Though French law does not in theory encourage the putting of a commercial value on the goodwill of a medical practice, holding that the confidence placed by a patient in his doctor is not an asset which can be priced in currency, there is a growing tendency for newcomers in a district to prefer the short-cut of a bought succession to the more laborious method known in the vernacular as squatting. The transaction between the incoming and outgoing possessor of a practice is often complicated by the transfer of a lease and medical and other fittings which are just as tangible as the goodwill of the patients is intangible and hypothetical. In a recent lawsuit, the purchaser of a practice disowned his signature to the deed of sale, pleading that he was free to cancel it as, according to the law, the confidence of the patients is no commercial commodity. While he lost his case, the situation with regard to the sale of a patient's goodwill is obscured rather than clarified: and the line separating the ethical from the unethical in this matter lacks definition. This is an additional reason for adhesion to a society whose technical advisers can pilot practitioners safely in these dangerous waters. The *Sou Médical* now has a membership exceeding 6000. There are five legal experts on its staff. The annual subscription is only 100 francs, and when an additional 50 francs are contributed as a subscription to the journal, *Le Concours Médical*, cover for half a million francs is provided in case of lawsuits. There are, of course, other concerns, not of a coöperative character, which do business in the same field. But the policies which they issue are apt to be worded with such forensic finesse that doctors may find it much easier to pay their subscriptions than to reap any benefit from them.

A DROP IN THE GOLD STANDARD

A recent discussion at the Société Médicale des Hôpitaux made it clear that the treatment of tuberculosis with gold has reached the negative phase which is apt to occur with all new treatments. With few remedies has the positive phase been so marked. For several years past gold treatment has been so popular that you had only to cough a little to qualify for it. The attack on it on this occasion was led by Prof. Emile Sergent, who referred to cases of gold poisoning he had seen in hospital and private practice as a sequel to the indiscriminating enthusiasm of his colleagues. As for the successes associated with it, he was inclined to suspect that the inherent tendency of tuberculous changes to retrogress had been—more or less unconsciously—exploited in favour of this last newcomer in the therapeutic field.

GOITRE

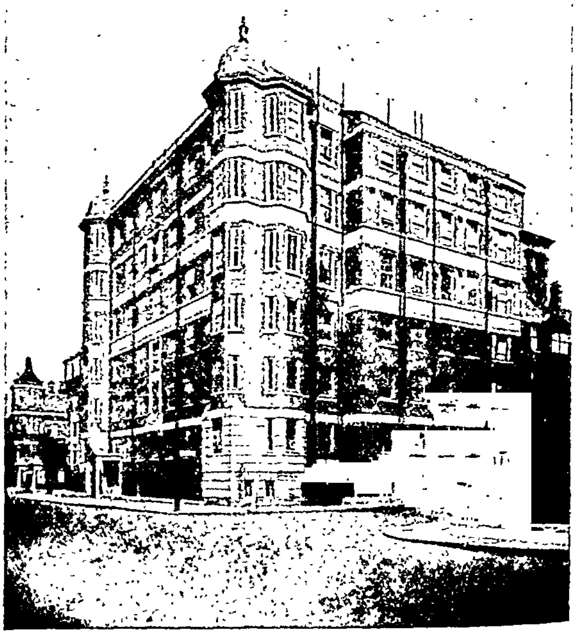
The tenth session of the Assises Nationales de Médecine Générale Française was devoted to a discussion of recent collective research into the nature of goitre. In many parts of this country goitre would seem to be on the wane, an improvement commonly attributed to better hygiene and, above all, to a better water-supply. In one area the diminution of goitre was associated with the introduction of sea fish and more meat in the dietary. In another area the influence of heredity was found to be so great that it was demonstrable on the distaff side in about 40 per cent. of all the goitres. While endemic simple goitre, when found in the large towns, would usually seem to be imported and not to have developed in them, the hyperthyreoses appeared, on the whole, to be more common in the towns than in the country (a difference less marked since 1918), and among the rich rather than the poor. Contributory factors are acute articular rheumatism, the infections of adolescence, typhoid fever and other water-borne diseases of the intestinal tract. In some areas hyperthyreosis is construed as a sign of resistance to tuberculosis; when the thyroid signs diminish, there is apt to be a recrudescence of an old pulmonary tuberculosis. While the advocacy of complete and prolonged rest in the early treatment of Graves's disease found little or no contradiction, opinions diverged on the merits of radiotherapy and operative treatment. The results of radiotherapy in 658 cases collected by Dr. J. Belot from various sources in Paris were very encouraging: failures 5 per cent., improvement in 25 per cent., recovery or great improvement in 70 per cent. Dr. H. Welti maintained that the results of thyroidectomy were superior, and that the claims made by the radiologists were not substantiated by surgeons who saw patients whom the radiologists had failed to cure. During the past five years he had performed 289 operations on 207 cases of exophthalmic goitre, with only one operative death. He had also operated on 167 goitres showing no signs of hyperthyroidism, and among them he had only two deaths to record. Another speaker tried to restore the balance by remarking that the radiologist is now beginning to see the operative failures of the surgeon. This was an interesting debate.

NEW RADIOLOGICAL DEPARTMENT AT THE CANCER HOSPITAL

ON Wednesday last H.M. the Queen opened the new buildings of the Cancer Hospital (Free) consisting of a private wing for paying patients, to be known as Granard House after the President of the Hospital, and of a new radiological department under the care of Prof. J. M. Woodburn Morison. The building also contains the new out-patient department which has long been badly needed. Our illustration shows the attractive frontage of the building on its corner site. The total cost of the new wing has been about £150,000.

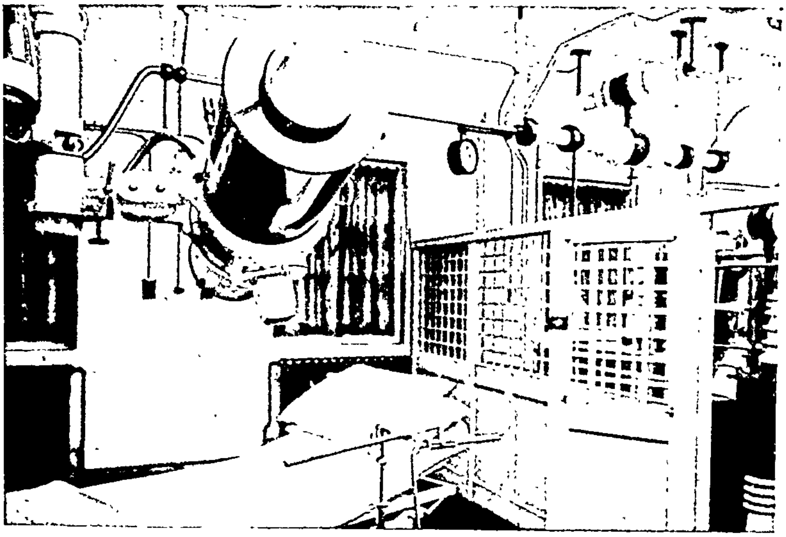
BEDS FOR PRIVATE PATIENTS

The first, second, and third floors of the building contain accommodation for 29 patients of limited means who can contribute towards the cost of their maintenance and treatment. The scale of maintenance fees, which has been approved by the Charity Commissioners, is 6 guineas per week in a single room, 5 guineas in a two-bedded, and 4 guineas in a three-bedded room. For radiological investigation the maximum charge is 5 guineas for a complete gastro-intestinal examination (exclusive of enema) with 3 guineas extra for an opaque enema; 3 guineas for examination of the urinary tract, with an additional fee for intravenous and retrograde pyelography; 2 guineas for investigation of the heart and lungs, or 3 guineas if stereoscopic films are taken; 1 guinea for investigation of either upper or lower extremity, or 2 guineas for a stereoscopic film of the shoulder. Other charges are in proportion. There is also a schedule of maximum charges for pathological examinations; the highest is 2 guineas chargeable for sugar-tolerance determination, preparation of autogenous vaccines, estimation of basal metabolic rate or histology of a frozen section taken at operation.



Profile of Granard House.

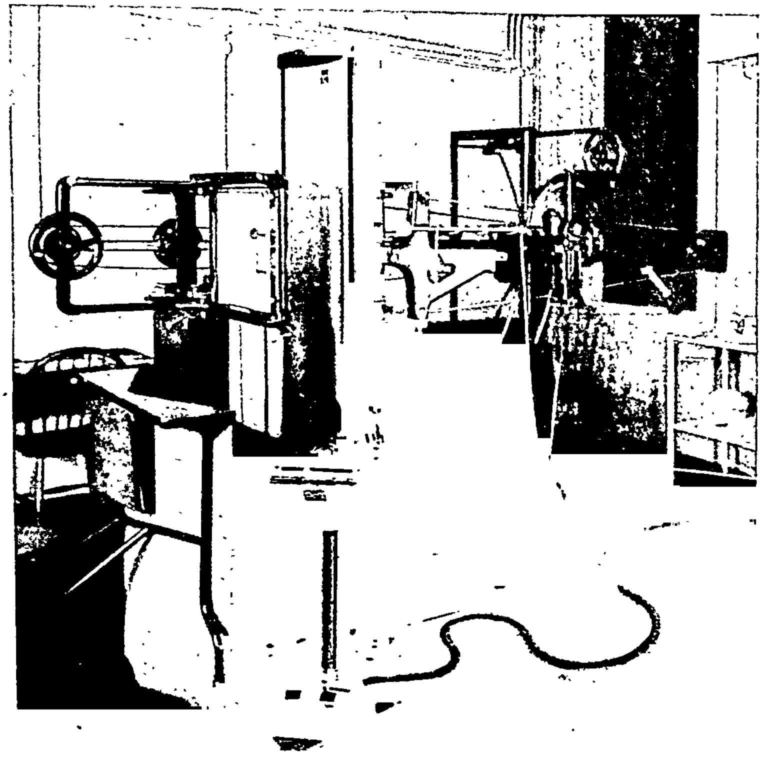
RADIOLOGICAL DEPARTMENT



Deep X ray therapy

This has been designed to secure the closest possible coöperation between clinical work on the one hand and scientific investigation on the other. Under the direction of the late Dr. Robert Knox the work of the department was found to be increasingly cramped for space and Prof. Woodburn Morison will now have three complete floors (fourth to sixth in the profile) under his direction. These are allotted to (1) physical investigations and the teaching of students, (2) X ray diagnostic work and radium treatment, (3) high voltage X ray therapy, artificial sunlight, and electrical treatment.

In association with the University of London and the Royal Colleges provision is made for post-graduate instruction of medical students in both clinical and scientific aspects of radiology. For this purpose a new lecture theatre and experimental laboratories are provided. Facilities are also available for the instruction of radiographers. The diagnostic section comprises rooms devoted to X ray investigation both by screening and by radiography, as well as the requisite dark-rooms, consulting- and dressing-rooms. We give an illustration of the arrangement of one of these rooms devoted to diagnosis. The high voltage X ray apparatus on the fifth floor (also illustrated) has been specially designed for the production of penetrating X rays. Special attention has been given to the protection of patient and operator and to the measurement of dosage. There is a wireless device by which the patient can speak to the operator some distance away.



Part of an X ray screening room

PHYSICS DEPARTMENT

This department, which is in charge of Mr. W. V. Mayneord, D.Sc., has been mainly concerned with the problems of X ray and radium dosage. When work was commenced, the only method of X ray dosage was with a barium platinocyanide pastille and a standard parallel plate was set up and calibrated in German r units before this was adopted internationally. Problems of distribution were next attacked, measurements in a phantom being made at 130 KV. pulsating potential, the maximum then available. Quite recently these measurements, with vastly improved apparatus, have been carried up to 400 KV., and demonstrate the striking improvement in depth dose and output now available.

The work on radium therapy has two aspects, theoretical and experimental. The distribution of radiation around various containers has been studied mathematically and experimentally, affording in many cases a fairly accurate idea of radiation fields. This work led to the design of surface applicators which give uniform irradiation, as well as charts enabling the correct amounts of radium in applicators of various sizes and various distances to be read off. Meanwhile, work has been done on the establishment of the r unit in gamma ray therapy, work which is now fairly complete. This should help in the standardisation and rationalisation of gamma ray therapy. Work has also been done on the variation of electron emission and possible sensitivity variations of tissues with wave-length, and some theoretical work is about to be published on the physical basis of biological action. Recently too the condenser dosimeter has been developed for both radium and X ray work, enabling both the quantity and quality of the radiation received in natural cavities of the body to be measured accurately.

Experimental work has also been carried out in conjunction with Prof. E. L. Kennaway on the optical properties of the carcinogenic hydrocarbons and allied substances. Biophysical problems are likely to be attacked in the future, now that means are available for measuring accurately and easily the various radiations used in clinical and experimental work.

Research in this department is financed chiefly by the hospital itself, but help is given by the British Empire Cancer Campaign, the Medical Research Council, and in certain directions by the International Cancer Research Foundation of Philadelphia.

"ACCREDITED MILK"

(FROM A CORRESPONDENT)

THE proposal of the Milk Marketing Board to add one more to the list of specially designated milks on the market will be received by the medical profession with rather mixed feelings. At the same time it is a highly important development and deserves detailed consideration, both on its merits and as an indicator of future developments in the long drawn out struggle for a clean safe milk-supply. It is a designated milk not sponsored by the Ministry of Health but introduced from the agricultural side, and those producers who comply with the requirements will be rewarded by receiving a bonus in the form of payment for their milk above the standard price given by the Milk Marketing Board, independent of their own exertions to sell the milk. The money will come out of the pool and is as such a contribution from all the milk producers. From this point of view it is wholly admirable, since the general effect must be to induce more and more producers to take the requisite steps to qualify for this additional payment and be placed on the roll of "Accredited Producers." Probably within a reasonably short time, a material proportion, even a majority, of the milk producers, will so qualify, and the whole standard of milk production will be raised and something which may fairly be called a clean milk-supply will be the general rule and not the exception. Put another way, those who do not conform to the new standard will be regarded as dis-credited milk producers, and it is not unreasonable to assume that as such their milk will be rejected for liquid consumption and they will have to be content with the much lower price payable for milk used for manufacturing purposes. Such no doubt is the laudable aim of the Milk Marketing Board, and their method of procedure is calculated to attain this object, using as it does the only practicable method to obtain a clean milk-supply, that of financial inducement.

But unfortunately, however, there is another side to the picture which induces considerable misgivings. To appreciate this aspect we have to consider the requirements necessary to be placed on the Roll of Accredited Producers. These are set out in the Report of the Reorganisation Commission for Milk (1933) and include :—

(*a*) The clinical inspection of herds and the elimination of diseased animals.

(*b*) The inspection of buildings to ensure compliance with a reasonable standard.

(*c*) The inspection of methods of producing and handling milk to secure compliance with a reasonable standard.

(*d*) The taking of, say, three surprise samples of milk over a period of three months and the satisfaction of a prescribed bacteriological standard.

Leaving out of consideration their indefinite nature and the considerable administrative problems involved, and assuming efficient control, it is obvious that at the best it is Grade A milk over again but with rather relaxed standards. And Grade A milk is fairly universally accepted as failing to give a safe milk-supply. It is well known that at least 40 per cent. of dairy cows are infected with tuberculosis, and it is notorious that clinical inspection will only eliminate a percentage of the infective animals, and a milk-supply free from tubercle bacilli cannot be guaranteed. The other three requirements refer to cleanliness of production. A cleanly produced milk-supply is highly desirable but merely a clean milk-supply is not a *safe* milk-supply. The risks of conveying to man tuberculosis, undulant fever, septic sore-throat, and the acute infectious diseases will be comparatively little reduced in the herds of accredited milk producers as compared with the ordinary producer. Stated briefly, the scheme of the Milk Marketing Board will materially assist in the production of a clean milk-supply but will do comparatively little to give a safe milk-supply, and it is a *safe* milk-supply which is insistently demanded by the medical profession.

The hope of the Milk Marketing Board that the new step will lead to an increased public confidence in the milk-supply with an added consumption is unlikely to be realised because an essential factor is lacking, the confidence and support of the medical profession. This can only be won by a *safe* as well as a *clean* milk-supply, and it is important to state this clearly. The proposal is one step in the right direction but not the only one and not even the essential step. In view of our infected herds and the impossibility of obtaining disease-free herds within a reasonable period, the only method available to give a safe milk-supply is efficient pasteurisation. A roll of accredited producers combined with pasteurisation of the milk supply would be a most valuable combination, but the Milk Marketing Board gives no sign that it appreciates this essential requirement. Without it the hope of a much larger consumption of liquid milk, which is so much needed both from the nutritional point of view and to help the milk producers, is likely to remain a hope unrealised. The medical profession wishes to help but it is unalterably opposed to anything short of a *safe* milk-supply.

One minor criticism may be mentioned. The name "accredited milk" is not a happy one. The expression "accredited" has become closely associated in U.S.A. and elsewhere, and is now being introduced into schemes in England and Scotland, for dairy herds which are accredited as free from tuberculosis. It is confusing to use the same term for milk supplied from herds which are not free from tuberculosis and which are not required to be so free. This expression "accredited" is firmly fixed in its usage for tuberculosis-free herds and should not be used with a quite different meaning. The nomenclature of designated milks is already confused and misleading and it is unfortunate that a fresh source of confusion is proposed to be introduced.

PUBLIC HEALTH

THE PRE-SCHOOL CHILD

A STUDY IN NUTRITION

So many of the measures adopted by health departments for safeguarding the health of children are founded either on general medical conceptions or the practice of other areas, that it is pleasing to notice an ad-hoc medical investigation leading up to concrete proposals. An enquiry into the physical condition of children between one and five years of age, in relation to their environment and social circumstances, has been conducted for Newcastle City Council by Dr. J. C. Spence, and it forms the text of a report [1] by the medical officer of health, Dr. J. A. Charles, on the social and administrative shortcomings which conduce to the state of affairs revealed. Three groups of poorer class children, totalling 125, and belonging in 113 instances to families where the breadwinner was unemployed, were submitted to careful medical scrutiny, their medical histories studied, and their home conditions investigated. The families chosen were regarded as fair samples of the class patronising clinics and similar social institutions. At the present time these inevitably include a large proportion of unemployed. As controls 124 children of the professional or well-to-do commercial class were examined by Dr. Spence. The numbers are admittedly small, but thorough clinical examination of the children by one examiner, or under his direction, was thought to be more reliable than an analysis of more numerous records compiled by a number of independent clinicians, and the time available placed a restriction upon the number of observations. In the first instance the children were classified from inspection under broad descriptions of the usual kind—good and satisfactory general condition, poor and unsatisfactory general condition and remainder. Inevitably this grouping was found to be deceptive in many instances in the light of more thorough clinical examination. This examination was directed specially to the following points—viz., height and weight, past or present rickets, anæmia, deficiency diseases and past illnesses.

Charts illustrating the distribution of heights and weights of the "professional families" class and the "labouring and artisan families" class are illuminating. Dr. Spence has adopted zones of heights and weights for each age as representing the normal ranges, and rightly describes these as constituting a modest standard. Stated briefly in figures, the charts show that 25 per cent. of the professional class children were above and only 5 per cent. below the standard heights, while less than 2 per cent. of the poorer class were above them and 47 per cent. below. As to weights, 48 per cent. of the better class children were above standard and 13 below, as against corresponding percentages of 11 and 55 among the poor. In the search for signs of rickets, Dr. Spence's past work [2] has convinced him that X ray examination is essential, and 103 children were so examined after suspicion had been aroused by clinical tests. In only 5 cases was there evidence of active disease. In the pursuit of anæmia, hæmoglobin values over 75 per cent. were accepted as satisfactory and under 65 per cent. as definite evidence of the disease. Among 25 of the better class children, taken as controls, 21 gave hæmoglobin readings above 75 per cent. and none below 70 per cent. On the other hand, of 121 of the poorer children, only 24, or 20 per cent., had hæmoglobin values over 75 per cent., and 28, or 23 per cent., were definitely anæmic. There was a notable absence of other signs of deficiency disease. Enquiry into the history of illnesses revealed a significant difference between good and poor class children. Of the former, only 5 out of 124 had suffered from pneumonia or pleurisy or chronic or recurrent cough, compared with 49 of the 125 poor children. Bringing together all his observations, Dr. Spence found that out of 125 poor children 45 (36 per cent.) were unhealthy or unfit and in 20 of these cases he considered that preceding illness was the starting-point of the unfitness; in the other 25 he could find no cause but improper or inadequate diet. As regards housing, he found that 27 poor children whom he was able to accept as healthy were living in houses with an average occupancy of 1·7 persons per room, while the 45 unhealthy were in more congested homes with an average of 2·6 persons per room. His conclusions are that the physical unfitness, giving rise to an appearance of malnutrition among 36 per cent. of poor children, is preventable, since the condition is much less frequent among the well-to-do; that the main immediate cause is physical damage by infective disease; and that the main factors which promote and perpetuate it are overcrowding in houses and insufficient diet. The relative importance of housing and dietary he suggests as a subject for a much larger enquiry, and it is clear from recent medical and political controversies that there is need for definite knowledge on such matters.

In commenting on the findings of Dr. Spence, Dr. Charles points to the heavier and earlier incidence of measles and its consequent influence upon mortality and chronic catarrhal disease in the more congested areas of the city. He shows that the results of this minute enquiry are in correspondence with the general findings among school entrants. In Newcastle it has been found that, among a small recent sample of the unemployed, the weekly expenditure on food averaged 4*s.* 5·8*d.* per man value, and at the prices reigning at that time a minimum adequate dietary would have cost 5*s.* 7½*d.* on the B.M.A. Committee's standard, or 5*s.* 1½*d.* on that of the Committee on Nutrition of the Ministry of Health. Consequently, he urges again the need for a forward policy in housing, increased hospital provision for measles and whooping-cough, more liberality in the assistance of the unemployed, and wider application of those measures for the care of "toddlers" which maternity and child welfare and education committees are permitted to take.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 28TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 9 (last week 3); scarlet fever, 2742; diphtheria, 1122; enteric fever, 31; acute pneumonia (primary or influenzal), 1163; puerperal fever, 36; puerperal pyrexia, 114; cerebro-spinal fever, 36; acute poliomyelitis, 6; acute polio-encephalitis, 1; encephalitis lethargica, 15; dysentery, 32; ophthalmia neonatorum, 100. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 7th–8th was as follows: Small-pox, 8 under treatment, 0 under observation (last week 11 and 0 respectively); scarlet fever, 1598; diphtheria, 1657; measles, 2857 (last week 3171); whooping-cough, 303; puerperal fever, 38 mothers (plus 14 babies); [illegible] 258; poliomyelitis, 2; "other diseases," [illegible] Hospital there were 15 babies (plus 6 m[illegible] neonatorum.

Deaths.—In 118 great towns, including London, there was no death from small-pox or enteric fever, 103 (46) from measles, 6 (1) from scarlet fever, 36 (6) from whooping-cough, 53 (12) from diphtheria, 49 (13) from diarrhœa and enteritis under two years, and 81 (17) from influenza. The figures in parentheses are those for London itself.

Measles is still diminishing, although this week there were 10 fatal cases in Liverpool and 6 in Newcastle-on-Tyne. Whooping-cough also caused 10 deaths in Liverpool and 5 in Birmingham. Fatal cases of influenza were chiefly confined to the northern and midland areas: Manchester reported 6 deaths, Leeds and Liverpool each 4; Birmingham reported 9 deaths and Newcastle-under-Lyme 3. Six fatal cases of diphtheria occurred at Manchester. Five fatal cases of diphtheria occurred at Liverpool, no more than 2 elsewhere.

The number of stillbirths notified during the week was 282 (corresponding to a rate of 41 per 1000 total births), including 47 in London.

PANEL AND CONTRACT PRACTICE

An Apology for Rules and Regulations

In an interesting essay on health insurance in England, contributed by Sir Henry Brackenbury to a New England journal (New Eng. Jour. Med., April 19th, p. 851), is a frank admission of disquieting features in the scheme. The drawback most commonly mentioned is the multiplicity of rules and regulations about medical benefit. No doubt, Sir Henry says, there is a tendency to multiply and complicate these unnecessarily, but he assures his readers that most of them "arise from three extremely valuable, and probably unique, features embodied in the English system." These are:—

(1) Every registered medical practitioner has the *right* to be a member of the service unless and until it is proved that, because of misconduct, his continuance therein is detrimental to the service as a whole;

(2) The close approximation of the conditions of the service as between doctor and patient to those which obtain in private practice;

(3) The considerable share assigned to the profession itself in administration.

It is because of, not in spite of, the confidence in the profession which these features disclose, Sir Henry Brackenbury writes, that provision has to be made for the occasional delinquent. If the state has no right to choose which physician shall take part in the service, machinery has to be established for dealing with anyone who conspicuously fails in his duty. If the state has limited its function to bringing together doctor and patient, leaving them free thereafter to act in accordance with recognised or traditional methods, it must provide means whereby, in case of dispute, each may have a square deal. If the state leaves purely medical matters to be judged by a purely professional body, there must be some authoritative delimitation of the respective spheres and some prescribed means for action. All these statutory requirements, rules, and regulations, need not, he concludes, trouble the physician any more than the ordinary requirements of the penal code trouble the law-abiding citizen. In fact, they do not worry him overmuch; they exist largely for his own protection. There is, however, a certain type of mind which tends to be distracted by them, and therefore they should be made as simple and few as possible.

Contract Fees for Specialists

A report upon hospital and nursing-home schemes, issued by the executive committee of the National Association of Local Government Officers, suggests that specialist surgeons and physicians should reduce their fees to members of the Association. The committee was asked to devise some scheme to help such of their members and dependants as are at present outside the existing hospital aid societies. The only self-supporting scheme on an insurance basis likely to meet their needs is discovered in the Hospital Provident Association (associated with the Manchester and Salford Medical Charities Fund) under which free service—in voluntary hospitals, public health hospitals, or private nursing-homes—is offered to members with an income up to £600 per year, and grants in aid are made to those above this limit. The liability of the H.P.A. is limited to 40 guineas in any one year, no assistance being given for home medical treatment, or in cases of tuberculosis, maternity, mental, and certain infectious diseases. It is stated that this Association—

> "has made arrangements with a large number of hospitals . . . whereby up to a certain number of beds, cases for the Hospital Provident Association could be admitted at an agreed rate of 10 guineas a week, 5 guineas of which was for the hospital charges and the other 5 guineas placed in a hospital suspense account of the hospital out of which fees for surgeons, anæsthetics, &c. were paid. By this method patients could obtain their treatment more cheaply than if they went into a hospital where they paid probably a less amount for the residence and a greater amount for the operation. In other words, in a hospital under agreement with the Hospital Provident Association a person could have treatment and an operation of almost any magnitude or cost at the 'all-in' charge of 10 guineas a week."

It seems that under this scheme patients who could afford reasonable specialist fees—as they should be able to do if their income is approaching £600 a year—are getting specialist services at an improperly low rate. Operations are matters often of life and death; they should be considered to be capital charges and not such as have to be met out of an annual income. If a patient buys a house he does not say "I cannot pay £900 for it as my income is under £500 per year." It is a question whether the specialists on the staff of these hospitals "in the north-western districts" should not protest against the exploitation of their services by boards of management. Specialists and others give their services to hospitals to treat the poor of the community who cannot pay their ordinary fees. There is no reason why those who can afford to pay specialist fees should not cover their liability by some form of insurance, but that is a different thing from asking a specialist to share 15 guineas with an anæsthetist for an operation requiring three weeks stay in hospital.

MEDICAL EXHIBITION CENTRE.—The third floor and the basement of British Industries House, near Marble Arch, are to be devoted to a medical exhibition centre which will be run under the guidance of an advisory committee whose chairman is Dr. Alfred Cox (see THE LANCET, Feb. 10th, p. 310). The centre will be officially opened on July 18th.

CORRESPONDENCE

TESTS FOR MOTOR DRIVERS

To the Editor of THE LANCET

SIR,—In answer to Dr. Howard Mummery I would point out (as I stated in my letter to the *Times*, April 23rd) that the National Institute of Industrial Psychology has in fact evolved a shorter series of tests than that described by your representative. I have had an interview with the director subsequent to my letter and have his authority for making some further statements. The psycho-physical test should come first, as by that test it may be demonstrated that the applicant is totally unfit to drive, in which event the training should be no longer continued. This would save persons who are obviously unfit from being put to the expense and trouble of a quite useless training. The part of the programme at present in operation at the institute which it would be desirable or necessary to keep might be summed up under the following headings : (1) vision, (2) reaction time, (3) judgment of speeds, (4) judgment of distances, (5) resistance to distraction, (6) vigilance.

The technique of applying these tests could be learned by a man of average intelligence, with driving experience, within a fortnight, and the institute would undertake to select and train such persons. The cost of training of these prospective administrators of these psychophysical tests would be about £3 3*s.* for each, and the provision of apparatus for each centre roughly £60. Candidates might be tested in groups of six or even more, and the duration of the test might be shortened to 30 minutes. If the fee paid to each teacher for the tests were, say, £2 2*s.* an hour, the cost to the individual candidate would be quite small, well within the fee of 10*s.* now suggested in the Road Traffic Bill.

It will be noted that examinations of general medical fitness are not in the category of tests. It is obvious that no layman could be entrusted with a medical examination, but it is probable that the tests as described would reveal any gross disability, and attention would be thus directed to the necessity of a professional medical examination. To require a medical examination in all cases would entail so heavy an expense and so often be unnecessary that it would clearly be an impractical policy to press its enforcement upon all candidates to drive.

It will also be noted that the test of " confidence and general road behaviour in driving a model car through moving scenery," cited in my letter to the *Times*, has been omitted. The experience of nausea felt by your representative and by Dr. Mummery throws some doubt upon the value of this particular test, and a trial upon the road itself would probably meet with more support from public opinion. It happens also that the apparatus used at the institute in the performance of this test is the only really expensive item. I have consequently omitted this in the motion I have tabled (a copy of which I enclose herewith) for considering this subject in Committee, and I propose that the psychophysical tests as mentioned above shall be used in combination with a test upon the road itself of confidence and general road sense.

In conclusion, may I express my warm thanks for the support which you give to my plea to " enlist the help of the industrial psychologist in planning tests suitable for mass application."

I am, Sir, yours faithfully,

House of Commons, May 7th. E. GRAHAM-LITTLE.

THE SCOPE OF PSYCHOTHERAPY

To the Editor of THE LANCET

SIR,—As director of the Institute of Medical Psychology I am grateful for your annotation under this heading last week. Not only the physicians of this institute but all other psychotherapists of experience will agree with your two special points of emphasis. It is certain that the early treatment of " nervous " disorders must involve child psychiatry (a name that really is preferable to child guidance). It is equally true that increasing experience should lead us to better diagnosis so that the lengthy and costly methods of analytic treatment shall only be employed for those who are likely to respond adequately. We, here, have for long been attempting to achieve this state of affairs, and certainly we have always recognised " that a flair for the sympathetic handling of patients is not always combined in one and the same person with the ability and the experience that are necessary for competent diagnosis." Every patient who is sent by his doctor to the institute has two interviews, of approximately an hour each, for the purpose of diagnosis, one of which is purely physical and the other from the psychiatric angle. These interviews are carried out only by the senior and most experienced members of the staff. As a matter of fact approximately one in four of the patients referred here as suitable is turned down by the examining physicians.

It is more than doubtful, however, whether any clinician, in whatever branch of medicine his interests may lie, would agree with your suggestion that, in order to limit a waiting-list, only those patients who were capable of complete " cure " should be treated, and those with conditions capable of alleviation be excluded. You selected your figures from the institute's last report to back your argument. Might it not have been more relevant to say that though the physicians' estimates of improvement on discharge were conservative, in that particular group of ex-patients, after three years 31·1 per cent. reported themselves cured, while a further 30·3 per cent. reported improvement (*more than slight*) maintained ? Including this particular group of cases, the results of the follow-up of all ex-patients (averaged) shows that 33·5 per cent. are " cured " and the total of " cured " and " improvement maintained " together is 69 per cent. The proportion of patients who are not helped or who relapse is 16·5 per cent. This list does not compare unfavourably with figures of the other branches of medicine, and surely speaks quite well for the diagnostic skill that is shown in selection of patients.

The staff of this institute certainly welcome your criticism and your suggestion, but, from the point of view of those who are seriously concerned with the scope of psychotherapy, I think these further figures should be mentioned.

I am, Sir, yours faithfully,

May 7th. J. R. REES.

THE REGISTRATION OF OSTEOPATHS

To the Editor of THE LANCET

SIR,—Sir Ernest Graham-Little has reminded us that the Osteopaths' Registration Bill is now before Parliament, and I think that medical men at least should be acquainted with the truth about this movement.

In the first place, osteopathy has nothing whatever to do with "bone setting" or with manipulative surgery or the therapeutic manipulation of stiff joints. Manipulative surgery is now a recognised branch of orthodox surgical practice based upon sound pathological principles. Osteopathy was started little more than 50 years ago by a certain Dr. A. T. Still of Chicago, who enunciated the principle that "the law of the artery is supreme," and taught that practically all diseases are due to pressure upon the blood-vessels in the intervertebral foramina, brought about by (imaginary) displacements or "lesions" of the vertebræ. About 20 years later a man named Palmer, of Davenport, Iowa, announced that he had made the "discovery" that 95 per cent. of all diseases are due to pressure upon the nerves in the intervertebral foramina, brought about by the same (imaginary) displacements of the vertebræ. He enunciated the principle that "the law of the nerve is supreme," and he founded a school of chiropractic in opposition to the school of osteopathy previously founded by Still. The essence of both these doctrines is the treatment of *remote* diseases by the manipulation or "adjustment" of the imaginary spinal lesions which are supposed to be their cause.

These rival factions (to mention only two) have flourished exceedingly in the United States of America. But they have almost exhausted the field of credulity in that country, and they are now making the most strenuous efforts to secure a status which would enable them the better to exploit the resources of this country. It should be clearly understood that this is an American stunt; the British element in osteopathy is practically negligible. A few osteopaths have taken medical degrees, which means that they have had some sort of education, and it is remarkable that these men have at once discarded the cardinal doctrines of osteopathy and chiropractic, because they are obviously impossible. They have however substituted yet another doctrine, namely "congestion," due to the same imaginary displacements of the spine. This doctrine, of course, is equally fallacious but rather more subtle, because more difficult to disprove.

Enough has been said to show that these factions are not agreed among themselves as to which particular lie shall be put across the public as a cloak for empirical manipulation of the spine, and it will be interesting to see whether our enlightened legislators decide to give their official blessing to "the law of the artery" or to "the law of the nerve" or to all and sundry of these quack manipulators. It has been naïvely suggested that osteopaths do not require the full training of the medical curriculum to fit them for the practice of their art. One answer to this is that the last issue of an osteopathic journal that came into my hands was concerned entirely with the treatment of cancer of the uterus.

I am, Sir, yours faithfully,

London, W., May 7th. A. S. BLUNDELL BANKART.

To the Editor of THE LANCET

SIR,—Opposition from Sir E. Graham-Little, M.P., to the recognition and legal regulation of osteopathy has been so persistent that it does not surprise me to learn that he has put down a motion for the rejection of the Bill which Mr. Robert Boothby introduced into the House of Commons. It is surprising, however, that Sir E. Graham-Little should continue to use against the Bill arguments which have been more than once refuted. May I, as an osteopath, state the position as we see it?

As the law stands, any person can offer to diagnose and treat disease. There is nothing to prevent an unqualified person setting up in practice as a healer, provided that he does not use any title or description which suggests that he is a registered medical man possessing certain academic degrees which in fact he does not possess. I am, as an osteopath, as much opposed as Sir E. Graham-Little is, to exploitation of the public by unqualified practitioners, and I have taken an active part in promoting the Bill now before Parliament, with the object of prohibiting the practice of osteopathy by persons who are not in possession of the registrable qualifications prescribed and defined in the Bill. Apparently he does not yet realise that his opposition to the Bill is calculated to leave unremedied the scandal of unqualified practice. The organised osteopaths in this country are trying to close the door against the unqualified practitioner in their field of work. He is content to leave it open, not only as far as osteopathy is concerned, but generally as regards the healing arts.

I seriously doubt whether his attitude commands the assent of the medical profession as a whole. Even if it does, I am not without hope that Parliament will deal sympathetically with a Bill which simply lays down the principle that osteopathy shall be practised in this country by qualified persons and not by those who are unqualified.

Sir E. Graham-Little's letter leads to his now familiar conclusion that all the trouble between registered and non-registered categories of medical practice can be settled by the simple expedient of compelling everybody to qualify as medical men and allowing those who wish to specialise—in manipulative therapeutics, for instance—to do so by post-graduate study. This is no remedy at all for the scandal of unqualified practice, unless he proposes also to prohibit practice by non-registered persons. Does he propose this? I have not yet elicited a plain answer to this question—but it cuts, I submit, at the root of Sir E. Graham-Little's objection to our Bill.

I am, Sir, yours faithfully,
WILFRID A. STREETER,
Hon. Director, Osteopathic Defence League.
London, W., May 7th.

** That treatment ought to be rendered only by those who are, through training and examination, found to be fitted all will agree, but it does not follow as the hon. director of the Osteopathic Defence League presumes that medical men desire professional recognition for osteopaths. Osteopathy, as Mr. Bankart points out, is not manipulative surgery, but a system of therapeutics; and treatment given under this system has no scientific foundation.—ED. L.

THE DOSAGE OF ŒSTRIN

To the Editor of THE LANCET

SIR,—Recent work on substitution therapy by œstrin in castrated animals shows that enormous doses of 500,000 to 1,000,000 international units are required to replace completely the œstrogenic function of the ovary in a castrated woman. Prof. Dodds, in his Goulstonian lecture, published in your last issue, considers that smaller doses are and must be valueless in clinical medicine, and claims the support of most gynæcologists for this view. Many women, however, suffer from slight degrees of ovarian deficiency, and quite small doses of œstrin may well be effective in them, which would be valueless in a castrated baboon. I. F. Stein and M. L. Leventhal (Jour. Amer. Med. Assoc., 1932, xcviii., 621) record that out of ten women treated for amenorrhœa by the injection of 100 mouse units of œstrin, five became pregnant. Dr. Gardiner-Hill has reported (see THE LANCET, 1932, i., 188) on two patients with amenorrhœa and sterility who were given an injection of 180 and 200 mouse units respectively; both menstruated and both became pregnant.

In this connexion the following brief record of three cases in which pregnancy followed the oral administration of Progynon, a follicular hormone, may be of interest.

CASE 1.—Healthy woman, aged 27. Married for four and a half years; contraceptives never used. Consulted me for sterility in 1930. She gave a history of scanty menstruation, of short duration, and with a five weeks' interval ever since adolescence. Sexually cool. Pelvic organs normal. The only treatment given was one progynon dragée of 250 mouse units daily. After one month's treatment the period was only two days over the normal four weeks. After two months' treatment the interval was four weeks exactly. After three months' treatment pregnancy occurred. Parturition had to be induced owing to delay, and a Cæsarean section became necessary owing to some obscure abnormality of the muscular contractions of the uterus, and acute dilatation of the stomach subsequently occurred. The Aschheim-Zondek reaction was negative at four months.

CASE 2.—Married woman, aged 28, with one child aged 7. No contraceptives used for two and a half years. Desired a second child. This woman gave no history suggesting any ovarian deficiency, normal sexually, and the periods regular and normal. She was given one dragée of progynon of 150 mouse units daily for 16 days, after which pregnancy resulted and terminated normally.

CASE 3.—Healthy woman, aged 36. Married nine years. No contraceptives used for three years. Consulted me for sterility. She gave a history of periods of short duration and slight loss, though regular in time, since adolescence. Sexually frigid. Treatment: one dragée of progynon of 150 mouse units daily for two months. During the third month two dragées were given daily. Pregnancy occurred at the end of the third month of treatment, and is proceeding normally. The Aschheim-Zondek reaction was reported as a "weak positive" at four and a half months. The œstrin content was within normal limits.

It is difficult to believe that the occurrence of pregnancy in these cases was either a coincidence only or the result of suggestion. Dr. Gardiner-Hill has suggested that such clinical results as these might be explainable on the "trigger" hypothesis of W. Shaw—a small dose stimulating a subfunctioning follicular apparatus to produce active follicles and so initiating the cycle which ultimately results in normal menstruation and pregnancy.

There is some evidence that a slight degree of anterior pituitary hypofunction also existed in two of my cases. I have treated one case of sterility on the above lines without success.

I am, Sir, yours faithfully,

Bridlington, May 5th. P. D. H. CHAPMAN.

BLOOD TRANSFUSION IN GASTRIC HÆMORRHAGE

To the Editor of THE LANCET

SIR,—Referring to Dr. Aitken's article in your issue of April 21st, I wondered if your readers would be interested in the blood-pressure findings in a series of cases investigated along lines similar though not so exhaustive as his. In 10 cases of hæmorrhage (5 of gastric or duodenal ulcer, 3 of pernicious anæmia, 1 of carcinoma of the stomach, and 1 of reactionary hæmorrhage) I took the systolic and diastolic blood pressure before, during, and ½, 1, 2, and 4 hours after transfusion. The transfusions were given by the Joubet syringe in 5 cases and with a Rotunda syringe using citrated blood in the remainder. The object of the investigation was to test the theory that a blood transfusion increases blood pressure, thus predisposing to further hæmorrhage. Far from this being the case, the effect noted in all these cases was a slight lowering of the systolic pressure during the transfusion and subsequently a pressure not significantly different from the initial readings except in one case where there was a drop from 150 to 120 mm. Hg.

In all 10 cases the transfusion was called for as an emergency method of treatment and 7 of the patients recovered and went home. Of the 3 who died, 1 had gastric ulcer, 1 pernicious anæmia, and 1 aplastic anæmia. The patient with carcinoma did not die until some time later. The series was a small one, but taken in conjunction with subsequent cases in which blood transfusion was *not followed by further* hæmorrhage, it suggests that the hypothesis that blood transfusion raises the blood pressure requires further inquiry.—I am, Sir, yours faithfully,

Radcliffe-on-Trent, Notts, May 2nd. H. A. PALMER.

PSYCHOLOGICAL MEDICINE AT THE NEW POST-GRADUATE SCHOOL

To the Editor of THE LANCET

SIR,—May I be allowed to reply briefly to Dr. Yellowlees's helpful letter in your last number, though I certainly cannot suggest, still less announce, any formal expression of policy on the part of the new school?

No courses have yet been arranged—indeed, Friday, May 4th, was the last date for applications for the four professorships. It is clear that, until these chief appointments have been made, no final decisions as to the remainder of the staff, or as to the character and duration of the courses to be provided, can be made.

Dr. Yellowlees may, I think, rest assured that the school, in appointing its teaching staff and in arranging for courses, will have before its notice the claims of psychological medicine and other subjects mentioned in the *Athlone Report of 1921*. Let me add that the school would welcome any suggestions, or indications of the desires of medical practitioners as to the courses to be provided.—I am, Sir, yours faithfully,

M. H. MACKEITH, D.M., M.R.C.P.,
Dean of the British Post-Graduate Medical School.
London, May 8th.

AN EARLY CASE OF X RAY DERMATITIS

To the Editor of THE LANCET

SIR,—About 1893 my brother, the late Dr. R. S. Nichol, of Manchester, was the victim in a revolver accident and received a bullet which lodged between the liver and the lung. The surgeons of that period had little or no experience of gunshot wounds, so it was wisely decided that, provided no bad results ensued, it would not be advisable to probe or essay an extraction of the bullet. The weapon was somewhat less than 0·320 in calibre and fired a lead bullet. Had it been a modern automatic with a nickel jacketed bullet and a powerful charge it is probable that the missile would have gone clean through the body without parking itself for future observation.

In 1895 came the news of the discovery of X rays and experiments were being carried out everywhere. By this time my brother was a medical student at the Victoria University, and hearing of the investigations then being made in the physics department, under the direction of Prof. Arthur Schuster, offered himself as a subject. Between 2 and 5 P.M. one afternoon he lay on a photographic plate, under a Crookes' tube, and took the prolonged and unbroken exposure. Unfortunately, good technique had not then been attained, and I think the attempt must have been futile as I do not remember hearing of any satisfactory photographic result. There was however a sequel to this exposure, for about ten days afterwards my brother showed me his chest and asked my opinion. I noticed a round discoloured patch about 8 inches in diameter, with the bullet wound as centre, very similar to a sunburn, or what we now see after an overdose of ultra-violet rays. The only conclusion I could come to was that the condition was directly due to the action of the X rays, and I urged my brother to make the discovery known. This he never did, and it was not until some time later that a similar phenomenon was observed and recorded. Perhaps one of your readers can tell me the first recorded case of X ray dermatitis.

My brother died in the Manchester Royal Infirmary in 1927, having never suffered any ill-effects from the embedded bullet.—I am, Sir, yours faithfully,

J. O. NICHOL, B.Sc., A.M.I.E.E.

Manchester, May 3rd.

A DISCLAIMER

To the Editor of THE LANCET

SIR,—In view of the publicity given in the press to my informal talk to the Ladies' Association of Queen Charlotte's Hospital, I should like to make it clear that I did not know that reporters were to be present, nor did I know that the proceedings were to be published.—I am, Sir, yours faithfully,

Harley-street, W., May 7th. LOUIS CARNAC RIVETT.

THE SELENIDE TREATMENT OF CANCER

Dr. A. T. TODD writes to point out that the annotation on p. 963 of our last issue gives too pessimistic an account of his results in the treatment of cancer. In particular the statement that ten of the patients described as apparent cures are alive "more than a year after the beginning of treatment" requires revision. The duration of the "apparent cures" is calculated, he informs us, from the *end* of treatment (which lasts at least a year) to the month of October, 1933, when his paper was compiled. At least 19 months, therefore, has now to be added to the duration of these "apparent cures" in order to obtain the period of survival as ordinarily reckoned; and on this it is seen that 7 out of 15 are alive and free from symptoms three years or more after their treatment began, while the other 8 have all survived more than two years. Publication of the figures has been delayed, Dr. Todd says, until it was likely that the results were reasonably permanent. He adds in conclusion: "Though I only accept what are called scrap-heap cases, there is no reason why the method should not be applied to current surgical practice. If my results in my cases are what is given, what is likely to follow the application of the method to cases after presumed complete operation?"

VACCINATION: THE MODERN VIEW

A LETTER from Colonel W. G. King, I.M.S. retd., and Major Myer Coplans, late R.A.M.C. (T.A.), reaches us commenting on the opening speech made by Dr. S. Monckton Copeman at the recent discussion under this heading which took place on Feb. 23rd in the section of epidemiology of the Royal Society of Medicine. The writers criticise Dr. Copeman for claiming to have introduced glycerinated lymph, but allow that his reference may have been due to the belated action of the British Government in issuing such lymph from an officially recognised institution. They consider that accuracy requires detailed mention of previous work in similar directions, and give detailed references in support, while they recognise that our report of Dr. Copeman's words was necessarily only a brief résumé.

Those who are historically minded may refer to a leading article in THE LANCET of April 28th, 1900 (p. 1216).

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. to be Surg. Capts.: G. R. McCowen, H. F. Briggs, C. F. O. Sankey, and F. J. D. Twigg.

F. H. Ward, E. J. Littledale, M. A. Rugg-Gunn, and S. H. Rhys Price to be Surg. Lts.

The following appointments are notified: Surg. Comdrs. G. B. Cockrem to *Effingham* and J. Kirker to *Victory*, for R.N.B.

Surg. Lt. Comdrs. E. C. Davis to *President* for course, and F. R. P. Williams to *Victory* for R.N.B.

Surg. Lt. J. G. V. Smith to *Pembroke* for R.N. Hospital, Chatham.

ARMY MEDICAL SERVICES

Col. W. D. C. Kelly, late R.A.M.C., retires on retd. pay.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. E. W. M. Paine, having attained the age for retirement, is placed on retd. pay.

Maj. C. L. Franklin to be Lt.-Col.

Maj. & Bt. Lt.-Col. C. H. H. Harold and Maj. D. W. Pailthorpe retire on retd. pay.

The undermentioned Lts. to be Capts. (Provl.): A. Macdonald and W. R. M. Drew.

Capt. J. C. Collins to be Maj.

TERRITORIAL ARMY

Lt. R. B. Brew to be Capt.

Lt. H. Rogers resigns his commn. and retains his rank.

Lt. W. F. Dorward resigns his commn.

E. H. Jaques (late Cadet, Durham Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

Supernumerary for service with O.T.C.—2nd Lt. R. W. Rattray to be Lt. supern. for serv. with Med. unit, Edinburgh Univ. Contgt., Sen. Div., O.T.C.

INDIAN MEDICAL SERVICE

Majs. M. L. Treston, A. Chand, R. Lee, T. S. Shastry, C. de C. Martin, J. H. Smith, J. B. de W. Molony, K. R. Batra, B. H. Singh, O. R. Unger, A. H. Harty, N. Briggs, F. R. Thornton, R. L. Vance, F. Griffith, and J. P. Huban to be Lt. Cols.

Temp. Lts. T. R. Pahwa, M. A. Gaffar, and J. N. Vasudeva to be Temp. Capts.

The undermentioned Lts. (on prob.) are rest. to the estabt.: W. M. E. Anderson and J. W. D. Goodall.

P. I. Franks, H. B. Wright, J. M. Davidson, D. P. Dewe, M. G. Leane, and G. E. S. Stewart to be Lts. (on prob.).

Lt.-Col. S. J. Bhathena retires.

ROYAL AIR FORCE

Flight Lt. (Hon. Squadron Leader) G. S. Ware relinquishes his temporary commission on completion of service and is permitted to retain the honorary rank of Squadron Leader.

Flight Lt. (Hon. Squadron Leader) J. G. Skeet relinquishes his temporary commission on completion of service.

COLONIAL MEDICAL SERVICE

The following appointments have been made: Dr. H. C. Armstrong, Dr. J. W. Denoon, Dr. F. J. Sladen, and Dr. G. Watt, Medical Officers to the Gold Coast, and Dr. N. E. W. Anderson, Dr. S. A. B. Black, Dr. R. D. Harding, Dr. A. C. Howard, and Dr. T. H. L. Montgomery, Medical Officers, Nigeria. Dr. W. K. Connell becomes a Junior Surgical Specialist, and Dr. C. F. Shelton a Junior Medical Specialist, Tanganyika. Dr. H. M. Nevin has been appointed Pathologist II., Institute for Medical Research, in the Federated Malay States.

Dr. J. T. Lydon has been appointed Admiralty Surgeon and Agent for Kingstown, and Mr. P. J. Smyth for Dublin.

OBITUARY

JAMES HAIG FERGUSON, F.R.C.P., F.R.C.S. Edin., F.C.O.G.

CONSULTING GYNÆCOLOGIST TO THE LEITH HOSPITAL AND ROYAL INFIRMARY, EDINBURGH

WE regret to announce the death of the well-known surgeon and obstetrician, Dr. Haig Ferguson, which occurred on May 2nd at his house in Coates-crescent, Edinburgh, in his 73rd year.

DR. FERGUSON

[Photograph by [illegible]

James Haig Ferguson was born in 1862 the son of the Rev. William Ferguson, minister of Fossoway, and was educated at the Collegiate School, Edinburgh, and at the medical school of the University. A prominent student he graduated as M.B., C.M. Edin. in 1884, took the M.R.C.P. in 1887, was elected F.R.C.P. in 1889, and proceeded to the M.D. with honours in the following year. He obtained the F.R.C.S. Edin. in 1902, and from that time forward held a series of important posts connected with his chosen specialty as obstetrician and gynæcologist. He served as resident physician at the Infirmary, the Maternity Hospital, and the Edinburgh Hospital for Sick Children. He lectured on midwifery and gynæcology in the University medical school, was both gynæcological and clinical tutor at the infirmary, and was duly appointed assistant to the physician for diseases of women and obstetric physician to the New Town Dispensary. With such varied and excellent equipment in the three great branches of professional knowledge, it is not surprising that he proved to be a practical and successful lecturer and that his services were in demand as an examiner. He acted in this capacity in midwifery and gynæcology at the Royal College of Surgeons, Edinburgh, at the University of Edinburgh, and the University of Aberdeen, and he passed rapidly from assistant to full gynæcological physician at the institutions with which he was connected.

He soon began to communicate to the medical press on obstetrical and gynæcological subjects, writing interesting notes for the *Edinburgh Medical Journal* and especially for the transactions of the Obstetrical Society of Edinburgh, while the reports of the Royal Infirmary contain also papers from him. He wrote a "Notebook of Obstetrical Nursing" in collaboration with the late Dr. F. W. N. Haultain, his colleague at the Public Dispensary, which went through several editions, the fifth one appearing in 1906; he collaborated also in a text-book of "Obstetrics and Gynæcology," and contributed to the "Encyclopædia Medica."

His academic and practical work and the all-round nature of his experience and acquirements fitted him inevitably for high official posts. Like many prominent Edinburgh men he started with presiding over the Royal Medical Society, later he was president of the Edinburgh Obstetrical Society—this twice with some interval, he served the Edinburgh Harveian Society in the same capacity, and was president of the Royal College of Surgeons of Edinburgh for the years 1929–31. He was an F.R.S. Edin. and received the hon. degree of LL.D. from his University and was one of the first Fellows of the College of Obstetrics and Gynæcology. In due course he became consulting physician to the Royal Infirmary, the Leith Hospital, and the Royal Maternity Hospital, while he was for a period chairman of the Central Midwives Board for Scotland. In this capacity he proved himself indeed the right man for the post. He dealt with the problems of the Board in a catholic spirit and was vigilant in seeing that the regulations were drawn in a generous manner, so that the Board was able to examine candidates for the certificate from continental countries and from the U.S.A., a certain reciprocity in registration becoming possible. He was of practical assistance to the General Medical Council in dealing with the situations arising both from the supply of suitable cases for teaching purposes and with the superintendence of the students' education. As a disciplinarian he was fair. He never hesitated to take any steps necessary to deal with unprofessional conduct among midwives, but he was sympathetic in his outlook and in particular he never forgot the public standpoint. As an example of his readiness to adjust the working of the Board to varying interests there may be mentioned his arrangement of a full-dress discussion on notification of puerperal pyrexia with the Obstetrical Society of Edinburgh and with representatives of the public authorities, when his freedom from prejudice stood him in good stead by securing the coöperation of general practitioners.

Ferguson worked at a very high pitch and it seems probable that his relatively early death was related to his unceasing activity and to the large demands on his professional attention. His periods of relaxation were few and took the form of spending short periods at Loch Rannoch. He will be greatly missed by patients, students, and professional colleagues, for he combined first-class professional competence with highly sympathetic personal qualities.

Dr. Ferguson, who was a member of the King's Bodyguard for Scotland (Royal Company of Archers), married in 1889 Penelope Gordon, daughter of the well-known surgeon, the late Sir Patrick Heron Watson, by whom he had one son and three daughters.

Prof. R. W. Johnstone writes: "Dr. Haig Ferguson's death leaves a great blank in the hearts of his friends. His strong but gracious personality never failed to leave an impress for good upon everyone with whom he came in contact. He was a man of handsome physical presence with a noble head and features, which, as age whitened his hair and care lined his face, became imbued with the very spirit of benevolence. His mere presence, as many a patient can attest, brought a helpful influence in all circumstances—comfort, encouragement, strength, good humour, gentleness, charity. An unusually high sense of duty dominated his whole character and life, involving self-sacrifice and self-expenditure to a degree that sometimes seemed almost quixotic but never other than wholly admirable and lovable to those less endowed with it than himself. Such was the charm of character and personality which he radiated that it tends to eclipse in one's mind the greatness of his more strictly professional attainments.

He was, however, a man with fine intellectual gifts. It was inevitable that such a man should obtain a very large practice, and he thus acquired a vast and varied practical experience. He was an exceptionally skilful obstetrician, endowed with that most important of all gifts in such work, patience. As a gynæcologist his sympathy and understanding led him to the heart of the psychological troubles that so often obscure the physical causes of the diseases of women, and gave him the unbounded confidence of his patients. As an operator he was sound and reliable rather than spectacular, and his results were very good. His professional interests were primarily clinical rather than scientific, and this is shown in his writings which are instinct with the wise judgment born of a wide practical experience. The same applies to his teaching, which while revealing a comprehensive knowledge of his subject was always mainly focused on the problem of how best to treat the individual patient. No student or visitor to his wards could fail to benefit from his clinical teaching, and probably none left without perceiving and acquiring something of his high sense of duty to his patients and of his high standard of professional conduct.

"The Transactions of the Edinburgh Obstetrical Society, of which he was twice president, show that Dr. Haig Ferguson was ever active in recording cases of special interest and in contributing papers on questions of practical importance. Amongst his recent contributions to obstetrics and gynæcology his modification of the axis-traction forceps is perhaps the most outstanding, the instrument being one of great practical value. He was also joint author of a well-known 'Combined Textbook' of both subjects, which recently went into a second edition. At the time of his last illness he was engaged in laboriously investigating the records of maternal mortality for the Scottish Department of Health.

"His patience, sagacity, and scrupulous fairness led to much administrative work being placed on his shoulders. He gave endless time and thought to the work of the Central Midwives Board for Scotland, of which he was a member from its inception and chairman for many years up to the time of his death. The Royal Maternity Hospital, the Royal Hospital for Sick Children, the Queen's Institute of District Nursing, and many other boards obtained his active and devoted service. The Royal College of Surgeons, of which he was president in 1929–30, and the 'Extramural School' also claimed much of his interest, while he never failed in attendance upon the meetings of the Obstetrical Society, in which his vast experience and sound judgment were held in the truest respect. The Lauriston Home for Rescue Work owed its inception in large measure to him, and its work and welfare were always close to his heart.

"He was fond of open-air sport, angling and archery for example, but his devotion to his work gave him little time to indulge in them. He loved hospitality and was the most genial of hosts, and the best of dinner-table companions. It would be easy to continue the catalogue of his interests and activities, but in the end one comes back to the man himself. He was in very truth a 'beloved physician,' and a perfect Scottish gentleman."

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held to-day, Friday, May 11th, at the Miller General Hospital, Greenwich, London, S.E., at 8.45 P.M. Dr. Cassie Williams will give an address on cookery and its relation to medicine.

ALFRED RICHARDSON, M.B., B.S.Lond., F.R.C.S.Eng.

PROFESSOR, CLINICAL SURGERY, UNIVERSITY OF LEEDS; SURGEON, LEEDS GENERAL INFIRMARY

THE sudden death of Alfred Richardson on April 22nd at the age of only 49 years was a profound shock in medical circles and to his many friends in Leeds. He appeared to be the very embodiment of perfect health, gifted with magnificent physique, active, and happy in his work. We are indebted to Mr. L. R. Braithwaite for the following obituary notice:—

"Richardson was essentially a Leeds man. He was a brilliant student qualifying M.B., B.S., London, in 1907, and adding to his qualifying degrees distinction in pharmacology and honours in medicine. He became a house surgeon at the General Infirmary at Leeds and step by step was elected casualty officer, resident surgical officer, surgical registrar and tutor. During his residential appointments he gained the F.R.C.S. England, and was clearly destined for the surgical staff, to which he was elected as an honorary assistant surgeon in 1920, rising to the full staff in 1927.

"Amongst his many other appointments the one he loved best was that of visiting surgeon to the Ministry of Pensions Hospital, where he found himself in an atmosphere of camaraderie and courageous optimism which exactly suited him. The affection between him and his patients at this hospital has been vividly described, and was shown by the large attendance of ex-Service men at his funeral. It need hardly be said that he himself served throughout the war both at home and abroad. He was honorary consulting surgeon at the Ilkley Coronation Hospital, the Normanton and Castleford Hospital, and several others. He succeeded in gathering together a wide and busy practice, especially in areas north of Leeds, where his name was widely known. His services as an expert surgical witness were in constant demand and he had a very large practice in this branch of his profession, his patent sincerity and power of lucid exposition making him invaluable.

"Richardson's capacity for surgery as an art was remarkable. He was cautious, calm, gentle, and yet firm, having always uppermost in his mind the well-being of the patient. His value to the university as a clinical teacher has probably never been surpassed. He was a true 'text-book' man in that he tirelessly drove home the things that were needed to get a qualification; but he did much more than this, he taught the need for sympathy, gentleness, and most rigorous examination and investigation. His popularity with students was proverbial and no success pleased him more than this. When he was appointed professor of clinical surgery about a year ago it was felt that we had in sight the man who would some day lead the surgical side from the more senior chair, and were well satisfied that he would do it with the same quiet enthusiasm which characterised all his work. And those of us who met him so often in the course of the daily round will always value delightful recollections. He would come unexpectedly to one's theatre and look on with a merry twinkle in his eye and a jest on his lips. One would return the visit and be met by the same happy smile and a repartee humorous and caustic but never resentful.

"As a student he showed an unusual interest in and aptitude for sports; his physique made him a redoubtable boxer and footballer. He retained the closest interest in sport, especially in the medical school, up to the time of his death. All loved Richardson as a brother, and as such we mourn him."

NOTES ON CURRENT TOPICS

Lotteries and Hospital Finance

In the House of Lords on May 1st the debate was resumed on the second reading of the Betting and Lotteries Bill.—Lord Somerleyton said there was still a general opinion that the voluntary hospitals of this country were in danger and ought to be supported by sweepstakes or lotteries. The hospitals were, in fact, in a very flourishing condition considering the bad times through which the country had passed. In the year 1931 the aggregate surplus of the London hospitals was £76,000; in 1932 it was £101,000, and it was pretty certain they would be better still for last year. Voluntary gifts to provincial hospitals amounted in 1930 to £12,734,000, and in 1931 to £11,568,000; including London the total for 1931 was £13,741,000. All this voluntary support would be jeopardised by sweepstakes and lotteries.—Lord Luke said that if lotteries on a large scale were to be held in aid of hospitals they would dry up the present sources of voluntary effort, but the Bill wisely permitted competitions which contained an element of skill.—The Earl of Feversham, replying to the debate, said that if the State inaugurated or tolerated the inception of lotteries for the purpose of raising money for hospitals, there would not be the same response from private persons or the same individual interest taken by private persons in their maintenance.—The Bill was read a second time.

Bills Advanced

In the House of Commons on May 1st the Contraceptives Bill and the South Devon and East Cornwall Hospital, Plymouth, Royal Albert Hospital, Devonport, and Central Hospital, Plymouth (Amalgamation, &c.) Bill were introduced and read a first time.

In the House of Lords on May 2nd the Workmen's Compensation (Coal Mines) Bill and the Water Supplies (Exceptional Shortage Orders) Bill were read a second time.

HOUSE OF COMMONS

WEDNESDAY, MAY 2ND

Sanitary Conveniences in Highlands of Scotland

Mr. Leonard asked the Secretary of State for Scotland if he was aware that a complaint was lodged on Jan. 31st, 1933, and a copy sent to the Department of Health, regarding the structural, sanitary, and other defects of the farm of Udale, Ross, and Cromarty, and that the local authority decided that it was not reasonably practicable to introduce water into the houses or to provide water-closets, and that on Dec. 29th, 1933, his department reported that its engineering inspector had advised that it was reasonably practicable to provide water-closets and introduce water; and whether any steps had been taken to force the local authority to carry out its statutory duties.—Sir Godfrey Collins replied: The answer to the first part of the question is in the affirmative. With regard to the second part, the county council have taken steps to secure the introduction of water into the houses, and the provision of a chemical closet for each house. With regard to the third part, there is no further action which, in the circumstances of this case, I can take.

Charges at a Municipal Maternity Home

Mr. Anstruther-Gray asked the Minister of Health whether his attention had been drawn to the fact that the Ilford council maternity home had charged a police constable £13 10*s*. for 16 days that his wife was in the home; and, in view of the declared practice of the home to base their charges on the income of the patient, he would inquire into the case, in view of the fact that a police constable's wages were insufficient to support so heavy a charge.—Mr. Shakespeare replied: The question of the charges to be made at this home is a matter within the discretion of the town council, but my right hon. friend will communicate with the council and inform my hon. friend of the result.

Suggested Flogging for Burglars

Mr. Potter asked the Home Secretary if, having regard to the increasing number of burglaries and to the hardship and suffering caused to those affected thereby, he would introduce legislation making it a condition that, in conjunction with punishment inflicted upon the offenders, there should be administered so many strokes of the cat as may be recommended by his medical advisers in such cases.—Sir J. Gilmour: There has been a large increase in recent years in cases of "breaking and entering," but the increase has been comparatively small in the particular crime of burglary, which is limited to entry of dwelling-houses by night. A large number of offences of house-breaking and shopbreaking are committed by persons, often young persons or children, who enter small houses or shops which are temporarily unoccupied and take small sums of money. Of the persons found guilty in 1932 of breaking and entering one-third were under 16 years of age, and over one-half were under 21 years of age. I do not think that the suggestion of my hon. friend would be a suitable method of dealing with the situation.

Coal-miners and Silicosis

Mr. David Grenfell asked the Home Secretary the number of men employed in the coal-mining industry who had been certified to be disabled through silicosis; the number partially disabled; the number in receipt of compensation; and the number of fatal cases recorded since Jan. 1st.—Sir John Gilmour replied: Since June 1st, 1931, when the medical board was appointed, up to April 30th, 1934, there have been 437 coal-miners certified by the board as disabled; 129 of these were certified as partially disabled. Earlier comparable figures are not available. From Feb. 1st, 1929, when the Various Industries (Silicosis) Scheme came into operation, up to the end of 1932, compensation was paid in 143 cases of disablement. There was a large number of cases in 1933, but the precise figure is not yet available. The number of deaths certified since Jan. 1st last is 14.

THURSDAY, MAY 3RD

Sickness Benefit and Public Assistance

Mr. Holdsworth asked the Minister of Health whether he was now in a position to reply to the representations made to him by the National Conference of Friendly Societies concerning Section 48 of the Poor Law Act, 1930, in which attention was drawn to the wrongful action taken by the London County Council whereby members of friendly societies had been having their sickness benefit wholly included when incomes were being assessed, or the needs tests being applied, in respect of applications received by that body for public assistance; and whether he now proposed, as a result of what transpired in London, to issue a special instruction on the subject to all public assistance committees.—Sir Hilton Young replied: I have now received further legal advice in regard to the proper interpretation of Section 48 of the Poor Law Act, 1930, and I propose to communicate the effect of that advice to public assistance authorities at an early date, and to furnish the National Conference with a copy of the circular to be issued.

MONDAY, MAY 7TH

Milk Publicity Campaign

Mr. Maclay asked the Minister of Agriculture whether he would draw the attention of the Milk Marketing Board to the importance of commencing as early as possible an extensive advertising campaign to encourage the public to consume more milk.—Mr. Ormsby-Gore, First Commissioner of Works, replied: My right hon. friend is quite satisfied that the Milk Marketing Board fully realise the desirability of encouraging the public to consume more milk; and the hon. Member will recollect that the proposals which he explained in his statement on milk policy in this House on Feb. 22nd include the provision of funds for a publicity campaign. Schemes for that purpose are now being formulated.

Cleanliness of Imported Milk Products

Mr. LAMBERT asked the Minister of Health if he was satisfied that all imported milk products were produced from healthy animals kept in conditions of cleanliness.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied : My right hon. friend is not in a position to say that all milk products are made from healthy animals kept in conditions of cleanliness, but he understands that most of the imported products are made from pasteurised milk or cream.

Mr. LAMBERT : Are we to understand that any kind of muck can be brought into this country under the name of butter, made under the most filthy conditions ?

Mr. SHAKESPEARE : I am informed that no danger to public health is involved.

Lieut.-Colonel ACLAND-TROYTE : Is there no inspection at the port to see what is the condition of the butter brought in ?

Mr. HANNON : Are we to understand that the Government can introduce no machinery to test the quality of the original milk from which these products are manufactured ?

Mr. SHAKESPEARE : Of course we can introduce machinery, but I should not like to come to the House and ask for a large expenditure which I could not justify.

Mr. HANNON : Are the people of this country to feed on milk products made from milk of the composition of which we have no knowledge whatever ?

Sir W. WAYLAND : Has the hon. gentleman ever visited a Polish or Russian dairy farm ?

Mr. SHAKESPEARE said that if the product was in liquid form the Ministry had ample powers and regulations with regard to bacteriological examination, but as regards non-liquid products he was informed there was no danger to health.

TUESDAY, MAY 8TH

Milk-borne Diseases

Brigadier-General CLIFTON BROWN asked the Prime Minister whether he would publish the report of the scientific committee appointed by the Economic Advisory Council to consider the incidence of milk-borne diseases ; and whether steps would be taken to submit its findings to agricultural interests, as well as to medical authorities, before any legislative action was taken thereon.—Mr. MACDONALD replied : The Committee's report has only just been received, and it has not yet been possible to consider the question of its publication. My hon. and gallant friend may rest assured that the interests of every section of the population will be carefully borne in mind by H.M. Government when they review the conclusions reached by the Committee.

Mr. LAMBERT asked whether, as this was a committee paid for by the taxpayer, the taxpayer could not have the benefit of their advice.

Mr. MACDONALD said that the rule had been that these reports were confidential until they were published; otherwise they remained confidential.

Mr. LAMBERT asked if he was aware that this question of milk-borne diseases was of extreme importance as affecting the agricultural industry, and if he would, if possible, publish the report.

Mr. MACDONALD said that as soon as he had had an opportunity of reading the report himself he would decide whether it should be published or not. Naturally, all the bias was always in favour of publication.

Warren Fisher Report and Dental Officers

Captain ELLISTON asked the Secretary to the Treasury whether the recommendations of the Warren Fisher Report could be extended to include dental officers as submitted in a memorandum by the British Dental Association.—Mr. HORE-BELISHA replied : The Committee on the Medical branches of the Defence Services suggested that some of their proposals in regard to the medical services might with advantage be applied to the dental services. I understand that representations have been made by the British Dental Association to the Defence Departments and that this question is now under consideration.

Charges for School Medical Treatment

Mr. DAVID DAVIES asked the Parliamentary Secretary to the Board of Education how much money was recovered fromparents in respect of charges for medical treatment during the last school year.—Mr. RAMSBOTHAM replied : The amount recovered from parents in respect of the medical treatment of children attending public elementary schools during the financial year 1931–32, the latest period for which complete audited accounts of local education authorities are yet available, was £69,370.

MEDICAL NEWS

English Conjoint Board

At the recent final examination of the Board the following candidates were approved in the subjects indicated, but are not yet eligible for the diploma of the Colleges :—

Pathology.—S. Alankaram, Madras and Roy. Free ; C. Anderson, St. Bart.'s ; W. G. R. Ashley-Emile, Middx. ; A. C. Ashton, Manch. ; S. H. Awad, Univ. Coll. and Glasg. ; K. C. Bailey, Camb. and St. Thos. ; E. B. D. Bangay, St. Bart.'s ; Mary Barber, Roy. Free ; C. Bard, Lond. ; R. I. Bence, Oxon. and Lond. ; H. B. Birnbaum, Glasg. ; J. R. Bodington, Camb. and Lond. ; E. J. J. Borges, Bombay and Middx. ; D. M. Bressler, St. Bart.'s ; B. B. Bridges, Camb. and Guy's ; J. L. Brown, Liverp. ; N. P. Brown, Camb. and Middx. ; R. W. D. Brownlie, Guy's ; E. W. Burstal, St. Bart.'s ; W. P. Cargill, Manch. ; R. M. Case, Birm. ; W. W. Cashmore, Camb. and Guy's ; R. C. F. Catterall, Camb. and Univ. Coll. ; J. G. Chappel, Univ. Coll. ; R. Clarke, Oxon. and St. Mary's ; Gladys E. Clyne, Roy. Free ; S. Cohen, St. Barts.'s ; N. D. Cousins, Manch. ; F. F. Croft, St. Bart.'s ; L. M. Curtiss, St. Bart.'s ; A. P. Dale-Bussell, Guy's ; M. C. Damkengrit, Camb. and St. Thos. ; S. M. Davidson, Camb. and St. Mary's ; C. E. M. de Gruchy and G. C. Denny, Guy's ; S. Devi, Roy. Free ; E. W. Dunkley, Lond. ; K. G. Eckersley, Leeds ; R. Farncombe, St. George's ; I. A. Feldman, Leeds ; J. D. Fergusson, Camb. and St. Thos. ; B. W. Fickling, St. George's ; W. J. Finegold, Charing Cross ; I. Finer, Guy's ; H. Firman, Manch. ; I. C. Fletcher, Camb. and Middx. ; J. R. Forbes, Guy's ; Margaret J. Foster, Camb. and Univ. Coll. ; Joan I. Franklin-Adams, Roy. Free ; E. Galinsky, Univ. Coll. ; J. E. Giesen, Guy's ; A. B. F. Gibson, Camb. and St. Thos. ; P. Glazer, King's Coll. ; C. H. Goodliffe, Birm. ; M. E. Gordon, Cardiff ; B. S. Grant, Lond. ; E. O'D. C. Grattan, Camb. and St. Thos. ; B. J. Green, and S. G. Griffin, Liverp. ; J. A. G. Hair, Univ. Coll. ; Irene G. Hamilton, Bristol ; E. E. Harris, Camb. and St. Bart.'s ; R. L. Hartley, Liverp. ; G. R. Hawkes, Camb. and Liverp. ; H. F. G. Hensel, Lond. ; T. H. Hills, Guy's ; C. A. Hinds Howell, Oxon. and St. Bart.'s ; J. Holden, Leeds ; D. A. B. Hopkin, St. Mary's ; J. J. V. Hopkins, St. Bart.'s ; J. H. Hovell, Charing Cross ; J. E. Ives, *Camb. and Univ. Coll.* ; J. I. A. *Jamieson*, Manch. ; J. E. V. Jones, Camb. and St. Thos. ; O. L. Jones, Liverp. ; D. Joy, Univ. Coll. ; G. H. W. Keates, Guy's ; W. E. Kershaw, Manch. ; A. W. Khan, Manch. ; E. L. Kirstein, Univ. Coll. ; E. H. Kitching, Leeds ; F. B. Lake, Guy's ; M. Lederman, Westminster ; M. J. Levi, Leeds ; W. Libertson, St. Bart.'s ; W. N. Lippitt, Birm. ; O. Lloyd, Middx. ; J. F. Lockwood, Guy's ; M. C. W. Long, St. Mary's ; E. B. McDowall, Camb. and St. Thos. ; H. M. McGladdery and R. McGladdery, St. Bart.'s ; *K. M. Mayall, Camb. and St. George's* ; *Ellen* Mayer, King's Coll. ; A. B. G. Mein, Westminster ; A. G. H. Menzies, Liverp. ; W. J. Mitchell, Guy's ; A. Moore, Univ. Coll. ; D. C. Moore, Manch. ; J. H. Moseley, Camb. and St. Thos. ; A. Mukerji, Middx. ; C. W. F. Outred, Guy's ; W. O. G. Paget, St. Bart.'s ; G. R. C. Palmer, St. Thos. ; R. L. Parish, Manch. ; G. W. V. Pegge, St. Mary's ; S. Phillips, King's Coll. ; E. H. Platts, Leeds ; A. W. Probert, Univ. Coll. ; J. Rabinovitch, Leeds ; J. Rapoport, St. Mary's ; H. W. Rees, Middx. ; W. G. S. Roberts, Birm. and *St. Thos.* ; *G. S. Robinson, Camb. and* Liverp. ; J. Robyns-Jones, Liverp. ; J. S. Ross, Camb. and St. Thos. ; Jean Ross, Univ. Coll. ; L. M. Rouillard, St. Thos. ; C. Royle, Manch. ; C. R. St. Johnston, Birm. ; S. V. Sansom, St. Bart.'s ; B. J. Shaw, Bir [illegible] Guy's ; H. Silman, Leeds ; A. S. R. Sinto [illegible] Smithson, Leeds ; B. P. Stone, King's [illegible] kes, Univ. Coll. ; E. W. Tapley, Manch. ; Dorothy H. Thomas, Univ. Coll. ; J. B. Tointon, Camb. and St. Thos. ; R. P. Tong, Liverp. ; B. M. *Truscott, Middx.* ; *R. W. D. Turner, Camb.* and St. Thos. ; M. M. Waldman, Westminster ; P. A. Walford, Camb. and St. Thos. ; T. J. Walters, St. Mary's ; F. G. Ward, Oxon. and St. Bart's ; M. Watkins, St. Mary's ; J. D. S. Watling and C. W. K. Willard, Univ. Coll. ; G. N. M. Wishart, Manch. ; H. L. Wolfe, St. Bart.'s ; G. M. Woolford, St. *Thos.* ; and H. Yarrow and J. G. Youngman, St. Bart.'s.

Medicine.—N. Angel, Birm. ; T. G. Armstrong, Camb. and Lond. ; E. C. Atkinson, St. Bart.'s ; Margaret D. Baber, Univ. *Coll.* ; J. C. *Baillie, King's Coll.* ; Mary Barber, Roy. Free ; G. Bates, Birm. ; R. I. Bence, Oxon. and Lond. ; D. Bickler, Leeds ; J. R. Bodington, Camb. and Lond. ; E. J. J. Borges, Bombay and Middx. ; D. M. Bressler, St. Bart.'s ; Jean M. Cass, Roy. Free ; R. Clarke, Oxon. and St. Mary's ; S. G. Clayton, King's Coll.; J. E. Darlow, Guy's; G. R. Davis, King's Coll.; N. J. Dias, St. Bart.'s; Dorothy S. Radcliffe Drew, Roy. Free; F. I. Evans, Camb. and Guy's; J. D. Fergusson, Camb. and St. Thos.; H. P. Fernandes, St. Bart.'s; Mervia Forrester-Jones, West Lond.; J. French and L. D. R. Frost, St. Bart.'s; D. J. Gilbert, King's Coll.; A. J. Glazebrook, St. George's; M. E. Gordon, Cardiff; E. O. C. Grattan, Camb. and St. Thos.; C. E. Greenwood, Oxon. and King's Coll.; P. R. Greeves, Oxon. and Middx; E. E. Harris, Camb. and St. Bart.'s; G. W. Hayward, St. Bart.'s; C. C. Hurst, Manch.; J. H. Lankester, Camb. and St. Thos.; W. Libertson, St. Bart.'s; W. N. Lippitt, Birm.; A. J. McCall, Liverp.; D. de la C. MacCarthy, St. Bart.'s; M. L. Meade-King, Camb. and Westminster; A. Moore, Univ. Coll.; G. H. Moore, Manch.; P. Morris, Westminster; R. M. Noordin and A. J. Owston, St. Bart.'s; W. H. Phillipps, Camb. and St. Thos.; W. H. A. Pieton, Oxon. and King's Coll.; R. M. G. Pole, St. Bart.'s; W. W. Roberts, Birm. and Sheff.; Katharine C. Rogers, Roy. Free; D. Sanyal, Lond.; I. C. Sarwal, Bombay and St. Bart.'s; S. R. Saunders, Cardiff; S. G. Shippard, King's Coll.; N. W. Sivolella, St. Bart.'s; A. F. Stallard, Camb. and St. Bart.'s; E. W. Tapley, Manch.; M. J. H. Thomas, Univ. Coll.; R. W. D. Turner, Camb. and St. Thos.; J. K. R. Waddington, Liverp.; B. Weiner, St. Bart.'s; and K. H. Wright, Guy's.

Surgery.—S. Alankaram, Roy. Free; A. G. V. Aldridge, Camb. and Birm.; I. J. Amorin, Manch.; W. G. R. Ashley-Emile, Middx.; C. H. Bliss and J. W. F. Brown, St. Thos.; E. J. Bury, Camb. and St. Mary's; I. Byer, St. Bart.'s; T. S. Cave, Camb. and King's Coll.; J. G. Chappel, Univ. Coll.; Gladys E. Clyne, Roy. Free; R. H. Dale, Camb. and St. Bart.'s; R. S. Dale, St. Mary's; J. R. Davidson, Univ. Coll.; D. H. Davies, Camb. and Middx.; G. M. Denning, Bristol and St. Mary's; A. R. O. Denton, Guy's; K. C. Eden, Univ. Coll.; T. S. Eddy and A. G. Edwards, Guy's; D. M. Evans, St. Bart.'s; E. W. R. Fairley, St. Thos.; E. L. Fisher, St. Bart.'s; P. S. Fox, Leeds; C. S. France, Manch.; C. M. Fysh, St. Thos.; A. B. F. Gibson, Camb. and St. Thos.; K. D. Gibson, St. George's; V. R. Ginde, Bombay and West Lond.; C. H. Goodliffe, Birm.; G. B. Grayling, Roy. Inf. Leicester; H. A. Hamilton, Camb. and Guy's; M. Hamilton, Univ. Coll.; W. H. C. M. Hamilton, Camb. and St. Thos.; G. R. Hawkes, Camb. and Liverp.; F. Janus, Manch.; F. J. G. Jefferiss, St. Mary's; J. R. R. Jenkins, St. Bart.'s; B. S. Jirge, West Lond.; D. R. Jones, Cardiff; P. G. C. Jones, Guy's; T. E. Jones-Davies, Camb. and St. George's; A. W. Khan, Manch.; M. B. Khan, Leeds; N. F. Kirkman, Manch.; J. L. Lanceley, Liverp.; W. A. Law, Camb. and Lond.; M. C. W. Long, St. Mary's; G. G. Macdonald, Univ. Coll.; E. B. McDowall, Camb. and St. Thos.; J. A. Mansi, St. Bart.'s; R. A. Mathews, Bristol; G. H. Moore, Manch.; R. S. Morris, Camb. and St. Thos.; E. J. Moynahan, Univ. Coll.; Edith A. S. Parry-Evans, Roy. Free; H. F. Patrick and S. H. Pearse, St. Thos.; G. W. V. Pegge, St. Mary's; R. Peters, Univ. Coll.; R. A. Piachaud, Ceylon and Univ. Coll.; T. H. Pierce, Liverp.; M. R. Preston, Middx.; E. J. Pryn, Guy's; R. H. Purnell, St. Bart.'s; S. Ramgoolam, Univ. Coll.; E. A. Richards, St. Thos.; Katharine C. Rogers, Roy. Free; I. Slome, Lond.; K. Soddy, Univ. Coll.; J. Starkie, Manch.; J. Stern and F. G. St. C. Strange, Lond.; J. C. Thomas, Univ. Coll.; Dorothy J. Thompson, Camb. and Bristol; R. C. H. Tripp and R. J. Vakil, St. Thos.; P. A. Walford, Camb. and St. Thos.; S. M. Whitteridge, Guy's; O. C. Wilkinson, Birm.; T. M. Williams, St. Thos.; P. L. E. Wood, Camb. and St. Thos.; R. F. Wyatt, St. Thos.; P. L. Young, St. Bart.'s; and Betty M. Zeal, Univ. Coll.

Midwifery.—A. G. V. Aldridge, Camb. and Birm.; A. W. H. Ashbery, Birm.; R. A. J. Asher, Lond.; G. T. Balean, Guy's; Phyllis M. Ball, Birm.; C. R. Barker, Univ. Coll.; D. Bhatia, West Lond.; A. P. Booth, Lond.; H. S. Brodribb, St. Bart.'s; J. A. B. Burnett, Charing Cross; Margaret M. B. Carey, Roy. Free; R. S. Carpenter, Lond.; Jean M. Cass, Roy. Free; R. C. F. Catterall, Camb. and Univ. Coll.; H. G. Ceresoto, St. Bart.'s; J. G. Chappel and S. C. Chatterjee, Univ. Coll.; W. E. Clarke, Charing Cross; W. B. Clegg, Guy's; A. B. Concanon, Liverp.; J. H. L. Conway-Hughes, St. Bart.'s; E. C. Cordeaux, Middx.; F. H. Culshaw and R. H. Dale, St. Bart.'s; J. R. Davidson, Univ. Coll.; D. A. Davies, Guy's; W. J. F. Davies, Cardiff; Bessie Dodd, Liverp.; E. W. Dunkley, Lond.; R. S. Ellis-Brown, Guy's; D. M. Evans, St. Bart.'s; E. W. R. Fairley, St. Thos.; A. Fearnley, King's Coll.; B. W. Fickling, St. George's; A. R. Ford, St. Bart.'s; I. M. Fradkin, Lond.; E. Galinsky, Univ. Coll.; V. R. Ginde, West Lond.; Muriel C. Goodchild, Roy. Free; C. H. Goodliffe, Birm.; B. S. Grant, Lond.; S. A. Greenwood-Penny, St. George's; W. E. Hadden, St. Thos.; H. A. Hamilton, Camb. and Guy's; M. J. Harris, Guy's; G. R. Hawkes, Camb. and Liverp.; G. H. M. Hemsted, St. Mary's; H. F. G. Hensel, Lond.; C. F. Heys, Guy's; K. F. W. Hinson and D. A. B. Hopkin, St. Mary's; J. J. V. Hopkins, St. Bart.'s; J. H. Hovell, Charing Cross; J. H. Hudson, Leeds; Ruth Hull, King's Coll.; J. J. Human, St. Mary's; B. S. Jirge, West Lond.; D. M. Jones, St. Bart.'s; R. N. Jones, Birm.; H. Kaplan, Cape and Guy's; M. R. Kark, Guy's; A. H. Khan, Birm.; E. L. Kirstein, Univ. Coll.; F. B. Lake, Guy's; F. H. Lamb, St. Thos.; M. Lederman, Westminster; A. R. Lee, Sheff.; F. D. M. Livingstone, Camb. and St. Bart.'s; O. Lloyd, Middx.; M. C. W. Long, St. Mary's; Christia F. Lucas, Birm.; A. J. McCall, Liverp.; R. McDonald, Guy's; E. B. Z. Masterman, Camb. and St. Bart.'s; J. G. Mathias, Lond.; D. Matthews, Cardiff; A. B. G. Mein, Westminster; R. L. Moody, St. Thos.; G. H. Moore, Manch.; A. Mukerji, Middx.; H. Nagler, Charing Cross; J. G. Nel, St. Bart.'s; W. S. Noble, Guy's; A. R. H. Oakley, Middx.; H. E. Osen, St. Bart.'s; S. Paletz, St. George's; Edith A. S. Parry-Evans, Roy. Free; Mary Paulosky, West Lond.; A. Pearlman, Middx.; A. L. Peers, Guy's; E. J. Perks, Bristol; S. Phillips, King's Coll.; Lillian M. Pickford, Univ. Coll.; G. Pollack, St. Mary's; T. S. Ross, Cape and St. Bart.'s; C. R. St. Johnston, Birm.; J. K. Samuel, St. Thos.; L. E. Sealy, Bristol; N. H. Seaton, Univ. Coll.; C. W. F. Shuttleworth, Guy's; J. Simon, Lond.; A. S. R. [illegible], Westminster; T. [illegible], St. Bart.'s; A. C. [illegible], Camb. and Middx.; F. G. St. C. Strange, Lond.; D. W. H. Thomas, St. George's; J. C. Thomas, Univ. Coll.; M. J. H. Thomas, Middx.; [illegible], Univ. Coll.; R. P. Tong, Liverp.; W. Wake, St. Bart.'s; M. N. [illegible], Lond.; J. K. R. Waddington, Liverp.; [illegible], St. Mary's; F. H. Waldman, Westminster; T. J. Walters, St. Mary's; [illegible] Watkins, Camb. and Manch.; J. G. Weston, Dubl. and Guy's; P. O. Wharton, [illegible]; S. M. Whitteridge, Guy's; O. C. Wilkinson, Birm.; A. E. Williams, Westminster; F. M. Wright, St. Bart.'s; [illegible] Yates, Lond.; and Winifred F. Young, Camb. and King's Coll.

University of London

During the period 1934–38 the faculty of medicine will be represented in the senate by Mr. H. L. Eason, M.S. (reappointed), and Dr. A. M. H. Gray. Mr. W. Girling Ball, F.R.C.S., will represent the general medical schools.

University of Birmingham

Dr. Stuart McDonald has been appointed lecturer in pathology in the university. He is at present demonstrator of pathology at the University of Durham College of Medicine, Newcastle-upon-Tyne.

Royal Medico-Psychological Association

The subject of the fifteenth Maudsley lecture, which Lord Macmillan is delivering to this association on Thursday, May 17th, at 3 P.M., will be the Professional Mind. The lecturer is president of the National Institute of Industrial Psychology. The meeting will take place at Manson House, 26, Portland-place, London, W.1.

Epsom College

The Council of Epsom College will shortly award a pension of £30 a year to a duly qualified medical man of not less than 55 years of age. If the candidate is a single man or a widower his income, independent of any allowance from the College or from the Royal Medical Benevolent Fund, must not exceed £100 per annum. Forms of application should be obtained forthwith from the Secretary, Epsom College, 49, Bedford-square, W.C.1, and must be returned completed to him not later than May 30th, 1934.

Tuberculosis Scholarships in Rome

The Italian Fascist National Federation against Tuberculosis has placed at the disposal of the Internat Union against Tuberculosis six scholarships at the Mussolini Institute in Rome. They are each of a of 6000 lire, plus board and lodging, and are inten enable foreign medical practitioners to stay at the ins and follow a course of studies. This stage of eight m will correspond with the academic year (from Nov. to July 15th) interrupted by the usual holiday perio

The scholarships will preferably be awarded to yo physicians who are already familiar with tuberculo problems, and the kind of work undertaken will be subj to agreement with the director of the institute.

Application should be made through the secretary the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock-square, London, W.C. 1, not later than July 1st.

London School of Hygiene and Tropical Medicine

The 1934–35 course of study at the school, whicl qualifies students to sit for the University of Londo diploma in public health, and covers a period of nin months' whole-time work, will begin on Oct. 1st. A open competition will be held on June 28th–29th for the Fishmongers' Company studentship which carries a free place in the course. Applications for this studentship must be sent in by June 18th to the secretary of the school, Keppel-street, Gower-street, W.C.1.

The Langley Memorial prize, of the approximate value of £21, is open to competition amongst officers of the West African medical staff, whether on the active or retired list. The award will be made for the best paper on tropical medicine or surgery; tropical hygiene and sanitation; or tropical entomology and parasitology. Special consideration will be given to original work. Papers must be delivered to the secretary of the school before Oct. 1st.

in this House on Feb. 22nd include the provision of funds for a publicity campaign. Schemes for that purpose are now being formulated.

Cleanliness of Imported Milk Products

Mr. Lambert asked the Minister of Health if he was satisfied that all imported milk products were produced from healthy animals kept in conditions of cleanliness.—Mr. Shakespeare, Parliamentary Secretary to the Ministry of Health, replied : My right hon. friend is not in a position to say that all milk products are made from healthy animals kept in conditions of cleanliness, but he understands that most of the imported products are made from pasteurised milk or cream.

Mr. Lambert : Are we to understand that any kind of muck can be brought into this country under the name of butter, made under the most filthy conditions ?

Mr. Shakespeare : I am informed that no danger to public health is involved.

Lieut.-Colonel Acland-Troyte : Is there no inspection at the port to see what is the condition of the butter brought in ?

Mr. Hannon : Are we to understand that the Government can introduce no machinery to test the quality of the original milk from which these products are manufactured ?

Mr. Shakespeare : Of course we can introduce machinery, but I should not like to come to the House and ask for a large expenditure which I could not justify.

Mr. Hannon : Are the people of this country to feed on milk products made from milk of the composition of which we have no knowledge whatever ?

Sir W. Wayland : Has the hon. gentleman ever visited a Polish or Russian dairy farm ?

Mr. Shakespeare said that if the product was in liquid form the Ministry had ample powers and regulations with regard to bacteriological examination, but as regards non-liquid products he was informed there was no danger to health.

TUESDAY, MAY 8TH

Milk-borne Diseases

Brigadier-General Clifton Brown asked the Prime Minister whether he would publish the report of the scientific committee appointed by the Economic Advisory Council to consider the incidence of milk-borne diseases ; and whether steps would be taken to submit its findings to agricultural interests, as well as to medical authorities, before any legislative action was taken thereon.—Mr. Macdonald replied : The Committee's report has only just been received, and it has not yet been possible to consider the question of its publication. My hon. and gallant friend may rest assured that the interests of every section of the population will be carefully borne in mind by H.M. Government when they review the conclusions reached by the Committee.

Mr. Lambert asked whether, as this was a committee paid for by the taxpayer, the taxpayer could not have the benefit of their advice.

Mr. MacDonald said that the rule had been that these reports were confidential until they were published ; otherwise they remained confidential.

Mr. Lambert asked if he was aware that this question of milk-borne diseases was of extreme importance as affecting the agricultural industry, and if he would, if possible, publish the report.

Mr. MacDonald said that as soon as he had had an opportunity of reading the report himself he would decide whether it should be published or not. Naturally, all the bias was always in favour of publication.

Warren Fisher Report and Dental Officers

Captain Elliston asked the Secretary to the Treasury whether the recommendations of the Warren Fisher Report could be extended to include dental officers as submitted in a memorandum by the British Dental Association.—Mr. Hore-Belisha replied : The Committee on the Medical branches of the Defence Services suggested that some of their proposals in regard to the medical services might with advantage be applied to the dental services. I understand that representations have been made by the British Dental Association to the Defence Departments and that this question is now under consideration.

Charges for School Medical Treatment

Mr. David Davies asked the Parliamentary Secretary to the Board of Education how much money was recovered fromparents in respect of charges for medical treatment during the last school year.—Mr. Ramsbotham replied : The amount recovered from parents in respect of the medical treatment of children attending public elementary schools during the financial year 1931–32, the latest period for which complete audited accounts of local education authorities are yet available, was £69,370.

MEDICAL NEWS

English Conjoint Board

At the recent final examination of the Board the following candidates were approved in the subjects indicated, but are not yet eligible for the diploma of the Colleges :—

Pathology.—S. Alankaram, Madras and Roy. Free ; C. Anderson, St. Bart.'s ; W. G. R. Ashley-Emile, Middx. ; A. C. Ashton, Manch. ; S. H. Awad, Univ. Coll. and Glasg. ; K. C. Bailey, Camb. and St. Thos. ; E. B. D. Bangay, St. Bart.'s ; Mary Barber, Roy. Free ; C. Bard, Lond. ; R. I. Bence, Oxon. and Lond. ; H. B. Birnbaum, Glasg. ; J. R. Bodington, Camb. and Lond. ; E. J. J. Borges, Bombay and Middx. ; D. M. Bressler, St. Bart.'s ; B. B. Bridges, Camb. and Guy's ; J. L. Brown, Liverp. ; N. P. Brown, Camb. and Middx. ; R. W. D. Brownlie, Guy's ; E. W. Burstal, St. Bart.'s ; W. P. Cargill, Manch. ; R. M. Case, Birm. ; W. W. Cashmore, Camb. and Guy's ; R. C. F. Catterall, Camb. and Univ. Coll. ; J. G. Chappel, Univ. Coll. ; R. Clarke, Oxon. and St. Mary's ; Gladys E. Clyne, Roy. Free ; S. Cohen, St. Barts.'s ; N. D. Cousins, Manch. ; F. F. Croft, St. Bart.'s ; L. M. Curtiss, St. Bart.'s ; A. P. Dale-Bussell, Guy's ; M. C. Damkengrit, Camb. and St. Thos. ; S. M. Davidson, Camb. and St. Mary's ; C. E. M. de Gruchy and G. C. Denny, Guy's ; S. Devi, Roy. Free ; E. W. Dunkley, Lond. ; K. G. Eckersley, Leeds ; R. Farncombe, St. George's ; I. A. Feldman, Leeds ; J. D. Fergusson, Camb. and St. Thos. ; B. W. Fickling, St. George's ; W. J. Finegold, Charing Cross ; I. Finer, Guy's ; H. Firman, Manch. ; I. C. Fletcher, Camb. and Middx. ; J. R. Forbes, Guy's ; Margaret J. Foster, Camb. and Univ. Coll. ; Joan I. Franklin-Adams, Roy. Free ; E. Galinsky, Univ. Coll. ; J. E. Giesen, Guy's ; A. B. F. Gibson, Camb. and St. Thos. ; P. Glazer, King's Coll. ; C. H. Goodliffe, Birm. ; M. E. Gordon, Cardiff ; B. S. Grant, Lond. ; E. O'D. C. Grattan, Camb. and St. Thos. ; B. J. Green, and S. G. Griffin, Liverp. ; J. A. G. Hair, Univ. Coll. ; Irene G. Hamilton, Bristol ; E. E. Harris, Camb. and St. Bart.'s ; R. L. Hartley, Liverp. ; G. R. Hawkes, Camb. and Liverp. ; H. F. G. Hensel, Lond. ; T. H. Hills, Guy's ; C. A. Hinds Howell, Oxon. and St. Bart.'s ; J. Holden, Leeds ; D. A. B. Hopkin, St. Mary's ; J. J. V. Hopkins, St. Bart.'s ; J. H. Hovell, Charing Cross ; J. E. Ives, Camb. and Univ. Coll. ; J. I. A. Jamieson, Manch. ; J. E. V. Jones, Camb. and St. Thos. ; O. L. Jones, Liverp. ; D. Joy, Univ. Coll. ; G. H. W. Keates, Guy's ; W. E. Kershaw, Manch. ; A. W. Khan, Manch. ; E. L. Kirstein, Univ. Coll. ; E. H. Kitching, Leeds ; F. B. Lake, Guy's ; M. Lederman, Westminster ; M. J. Levi, Leeds ; W. Libertson, St. Bart.'s ; W. N. Lippitt, Birm. ; O. Lloyd, Middx. ; J. F. Lockwood, Guy's ; M. C. W. Long, St. Mary's ; E. B. McDowall, Camb. and St. Thos. ; H. M. McGladdery and R. McGladdery, St. Bart.'s ; K. M. Mayall, Camb. and St. George's ; Ellen Mayer, King's Coll. ; A. B. G. Mein, Westminster ; A. G. H. Menzies, Liverp. ; W. J. Mitchell, Guy's ; A. Moore, Univ. Coll. ; D. C. Moore, Manch. ; J. H. Moseley, Camb. and St. Thos. ; A. Mukerji, Middx. ; C. W. F. Outred, Guy's ; W. O. G. Paget, St. Bart.'s ; G. R. C. Palmer, St. Thos. ; R. L. Parish, Manch. ; G. W. V. Pegge, St. Mary's ; S. Phillips, King's Coll. ; E. H. Platts, Leeds ; A. W. Probert, Univ. Coll. ; J. Rabinovitch, Leeds ; J. Rapoport, St. Mary's ; H. W. Rees, Middx. ; W. G. S. Roberts, Birm. and St. Thos. ; G. S. Robinson, Camb. and Liverp. ; J. Robyns-Jones, Liverp. ; J. S. Ross, Camb. and St. Thos. ; Jean Ross, Univ. Coll. ; L. M. Rouillard, St. Thos. ; C. Royle, Manch. ; C. R. St. Johnston, Birm. ; S. V. Sansom, St. Bart.'s ; B. J. Shaw, Bir [illegible] Guy's ; H. Silman, Leeds ; A. S. R. Sinto[illegible] Smithson, Leeds ; B. P. Stone, King's [illegible] kes, Univ. Coll. ; E. W. Tapley, Manch. ; Dorothy H. Thomas, Univ. Coll. ; J. B. Tointon, Camb. and St. Thos. ; R. P. Tong, Liverp. ; B. M. Truscott, Middx. ; R. W. D. Turner, Camb. and St. Thos. ; M. M. Waldman, Westminster ; P. A. Walford, Camb. and St. Thos. ; T. J. Walters, St. Mary's ; F. G. Ward, Oxon. and St. Bart's ; M. Watkins, St. Mary's ; J. D. S. Watling and C. W. K. Willard, Univ. Coll. ; G. N. M. Wishart, Manch. ; H. L. Wolfe, St. Bart.'s ; G. M. Woolford, St. Thos. ; and H. Yarrow and J. G. Youngman, St. Bart.'s.

Medicine.—N. Angel, Birm. ; T. G. Armstrong, Camb. and Lond. ; E. C. Atkinson, St. Bart.'s ; Margaret D. Baber, Univ. Coll. ; J. C. Baillie, King's Coll. ; Mary Barber, Roy. Free ; G. Bates, Birm. ; R. I. Bence, Oxon. and Lond. ; D. Bickler, Leeds ; J. R. Bodington, Camb. and Lond. ; E. J. J. Borges, Bombay and Middx. ; D. M. Bressler, St. Bart.'s ; Jean M. Cass, Roy. Free ; R. Clarke, Oxon. and St. Mary's ; S. G. Clayton, King's Coll.; J. E. Darlow, Guy's; G. B. Davis, King's Coll.; N. J. Dias, St. Bart.'s; Dorothy S. Radcliffe Drew, Roy. Free; F. I. Evans, Camb. and Guy's; J. D. Fergusson, Camb. and St. Thos.; H. P. Fernandes, St. Bart.'s; Mercia Force-Jones, West Lond.; J. French and L. D. B. Frost, St. Bart.'s; D. J. Gilbert, King's Coll.; A. J. Glazebrook, St. George's; M. E. Gordon, Cardiff; E. O. C. Grattan, Camb. and St. Thos.; C. E. Greenwood, Oxon. and King's Coll.: P. R. Greeves, Oxon. and Middx; E. E. Harris, Camb. and St. Bart.'s; G. W. Hayward, St. Bart.'s; C. C. Hurst, Manch.; J. H. Lankester, Camb. and St. Thos.; W. Libertson, St. Bart.'s; W. N. Lippitt, Birm.; A. J. McCall, Liverp.; D. de la C. MacCarthy, St. Bart.'s; M. L. Meade-King, Camb. and Westminster; A. Moore, Univ. Coll.; G. H. Moore, Manch.; P. Morris, Westminster; R. M. Noordin and A. J. Owston, St. Bart.'s; W. H. Phillipps, Camb. and St. Thos.; W. H. A. Pieton, Oxon. and King's Coll.; R. M. G. Pole, St. Bart.'s; W. W. Roberts, Birm. and Sheff.; Katharine C. Rogers, Roy. Free; D. Sanyal, Lond.; I. C. Sarwal, Bombay and St. Bart.'s; S. R. Saunders, Cardiff; S. G. Shippard, King's Coll.; N. W. Sivolella, St. Bart.'s; A. F. Stallard, Camb. and St. Bart.'s; E. W. Tapley, Manch.; M. J. H. Thomas, Univ. Coll.; R. W. D. Turner, Camb. and St. Thos.; J. K. B. Waddington, Liverp.; B. Weiner, St. Bart.'s; and K. H. Wright, Guy's.

Surgery.—S. Alankaram, Roy. Free; A. G. V. Aldridge, Camb. and Birm.; I. J. Amorin, Manch.; W. G. R. Ashley-Emile, Middx.; C. H. Bliss and J. W. F. Brown, St. Thos.; E. J. Bury, Camb. and St. Mary's; I. Byer, St. Bart.'s; T. S. Cave, Camb. and King's Coll.; J. G. Chappel, Univ. Coll.; Gladys E. Clyne, Roy. Free; R. H. Dale, Camb. and St. Bart.'s; R. S. Dale, St. Mary's; J. R. Davidson, Univ. Coll.; D. H. Davies, Camb. and Middx.; G. M. Denning, Bristol and St. Mary's; A. R. O. Denton, Guy's; K. C. Eden, Univ. Coll.; T. S. Eddy and A. G. Edwards, Guy's; D. M. Evans, St. Bart.'s; E. W. R. Fairley, St. Thos.; E. L. Fisher, St. Bart.'s; P. S. Fox, Leeds; C. S. France, Manch.; C. M. Fysh, St. Thos.; A. B. F. Gibson, Camb. and St. Thos.; K. D. Gibson, St. George's; V. R. Ginde, Bombay and West Lond.; C. H. Goodliffe, Birm.; G. B. Grayling, Roy. Inf. Leicester; H. A. Hamilton, Camb. and Guy's; M. Hamilton, Univ. Coll.; W. H. C. M. Hamilton, Camb. and St. Thos.; G. R. Hawkes, Camb. and Liverp.; F. Janus, Manch.; F. J. G. Jefferiss, St. Mary's; J. R. R. Jenkins, St. Bart.'s; B. S. Jirge, West Lond.; D. R. Jones, Cardiff; P. G. C. Jones, Guy's; T. E. Jones-Davies, Camb. and St. George's; A. W. Khan, Manch.; M. B. Khan, Leeds; N. F. Kirkman, Manch.; J. L. Lanceley, Liverp.; W. A. Law, Camb. and Lond.; M. C. W. Long, St. Mary's; G. G. Macdonald, Univ. Coll.; E. B. McDowall, Camb. and St. Thos.; J. A. Mansi, St. Bart.'s; R. A. Mathews, Bristol; G. H. Moore, Manch.; R. S. Morris, Camb. and St. Thos.; E. J. Moynahan, Univ. Coll.; Edith A. S. Parry-Evans, Roy. Free; H. F. Patrick and S. H. Pearse, St. Thos.; G. W. V. Pegge, St. Mary's; R. Peters, Univ. Coll.; R. A. Piachaud, Ceylon and Univ. Coll.; T. H. Pierce, Liverp.; M. R. Preston, Middx.; E. J. Pryn, Guy's; R. H. Purnell, St. Bart.'s; S. Ramgoolam, Univ. Coll.; E. A. Richards, St. Thos.; Katharine C. Rogers, Roy. Free; I. Slome, Lond.; K. Soddy, Univ. Coll.; J. Starkie, Manch.; J. Stern and F. G. St. C. Strange, Lond.; J. C. Thomas, Univ. Coll.; Dorothy J. Thompson, Camb. and Bristol; R. C. H. Tripp and R. J. Vakil, St. Thos.; P. A. Walford, Camb. and St. Thos.; S. M. Whitteridge, Guy's; O. C. Wilkinson, Birm.; T. M. Williams, St. Thos.; P. L. E. Wood, Camb. and St. Thos.; R. F. Wyatt, St. Thos.; P. L. Young, St. Bart.'s; and Betty M. Zeal, Univ. Coll.

Midwifery.—A. G. V. Aldridge, Camb. and Birm.; A. W. H. Ashbery, Birm.; R. A. J. Asher, Lond.; G. T. Balean, Guy's; Phyllis M. Ball, Birm.; C. R. Barker, Univ. Coll.; D. Bhatia, West Lond.; A. P. Booth, Lond.; H. S. Brodribb, St. Bart.'s; J. A. B. Burnett, Charing Cross; Margaret M. B. Carey, Roy. Free; R. S. Carpenter, Lond.; Jean M. Cass, Roy. Free; R. C. F. Catterall, Camb. and Univ. Coll.; H. G. Cereseto, St. Bart.'s; J. G. Chappel and S. C. Chatterjee, Univ. Coll.; W. E. Clarke, Charing Cross; W. B. Clegg, Guy's; A. B. Concanon, Liverp.; J. H. L. Conway-Hughes, St. Bart.'s; E. C. Cordeaux, Middx.; F. H. Culshaw and R. H. Dale, St. Bart.'s; J. R. Davidson, Univ. Coll.; D. A. Davies, Guy's; W. J. F. Davies, Cardiff; Bessie Dodd, Liverp.; E. W. Dunkley, Lond.; R. S. Ellis-Brown, Guy's; D. M. Evans, St. Bart.'s; E. W. R. Fairley, St. Thos.; A. Fearnley, King's Coll.; B. W. Fickling, St. George's; A. R. Ford, St. Bart.'s; I. M. Fradkin, Lond.; E. Galinsky, Univ. Coll.; V. R. Ginde, West Lond.; Muriel C. Goodchild, Roy. Free; C. H. Goodliffe, Birm.; B. S. Grant, Lond.; S. A. Greenwood-Penny, St. George's; W. E. Hadden, St. Thos.; H. A. Hamilton, Camb. and Guy's; M. J. Harris, Guy's; G. R. Hawkes, Camb. and Liverp.; G. H. M. Hemsted, St. Mary's; H. F. G. Hensel, Lond.; C. F. Heys, Guy's; K. F. W. [illegible] 's; J. J. V. Hopkins, St. B [illegible] ss; J. H. Hudson, Leeds; [illegible] Human, St. Mary's; B. S [illegible] t. Bart.'s; R. N. Jones, Bir [illegible] R. Kark, Guy's; A. H. Ki [illegible] Coll.; F. B. Lake, Guy's; F. H. Lamb, St. Thos.; M. Lederman, Westminster; A. R. Lee, Sheff.; F. D. M. Livingstone, Camb. and St. Bart.'s; O. Lloyd Middx.; M. C. W. Long, St. Mary's; Christia F. Lucas, Birm.; A. J. McCall, Liverp.; R. McDonald, Guy's; E. B. Z. Masterman, Camb. and St. Bart.'s; J. G. Mathias, Lond.; D. Matthews, Cardiff; A. B. G. Mein, Westminster; R. L. Moody, St. Thos.; G. H. Moore, Manch.; A. Mukerji, Middx.; H. Nagler, Charing Cross; J. G. Nel, St. Bart.'s; W. S. Noble, Guy's; A. R. H. Oakley, Middx.; H. E. Osen, St. Bart.'s; S. Paletz, St. George's; Edith A. S. Parry-Evans, Roy. Free; Mary Paulosky, West Lond.; A. Pearlman, Middx.; A. L. Peers, Guy's; E. J. Perks, Bristol; S. Phillips, King's Coll.; Lillian M. Pickford, Univ. Coll.; G. Pollack, St. Mary's; T. S. Protheroe, Guy's; R. H. Purnell, St. Bart.'s; C. O. Ribeiro, Univ. Coll.; D. T. Richards, Cardiff; S. Roberts, Bristol; Katharine C. Rogers, Roy. Free; M. Rooms and Eileen G. Rose, Leeds; W. T. Ross, Cape and St. Bart.'s; C. R. St. Johnston, Birm.; J. K. Samuel, St. Thos.; L. E. Sealy, Bristol; N. H. Seaton, Univ. Coll.; C. W. T. Shuttleworth, Guy's; J. Simon, Lond.; A. S. R. Sinton, Westminster; T. Smallhorn, St. Bart.'s; A. C. Spence, Camb. and Middx.; F. G. St. C. Strange, Lond.; D. W. I. Thomas, St. George's; J. C. Thomas, Univ. Coll.; M. J. H. Thomas, Univ. Coll.; R. P. Tong, Liverp.; B. M. Truscott, Middx.; J. K. B. Waddington, Liverp.; W. Waks, St. Bart.'s; M. M. Waldman, Westminster; J. St. J. F. W. Wallace-Collett, Lond.; T. J. Walters, St. Mary's; M. Watkins, St. Mary's; F. H. Weston, Dubl. and Guy's; D. O. Wharton, Camb. and Manch.; S. M. Whitteridge, Guy's; O. C. Wilkinson, Birm.; J. G. Williams, Westminster; P. M. Wright, St. Bart.'s; A. R. Yates, Lond.; and Winifred F. Young, Camb. and King's Coll.

University of London

During the period 1934–38 the faculty of medicine will be represented in the senate by Mr. H. L. Eason, M.S. (reappointed), and Dr. A. M. H. Gray. Mr. W. Girling Ball, F.R.C.S., will represent the general medical schools.

University of Birmingham

Dr. Stuart McDonald has been appointed lecturer in pathology in the university. He is at present demonstrator of pathology at the University of Durham College of Medicine, Newcastle-upon-Tyne.

Royal Medico-Psychological Association

The subject of the fifteenth Maudsley lecture, which Lord Macmillan is delivering to this association on Thursday, May 17th, at 3 P.M., will be the Professional Mind. The lecturer is president of the National Institute of Industrial Psychology. The meeting will take place at Manson House, 26, Portland-place, London, W.1.

Epsom College

The Council of Epsom College will shortly award a pension of £30 a year to a duly qualified medical man of not less than 55 years of age. If the candidate is a single man or a widower his income, independent of any allowance from the College or from the Royal Medical Benevolent Fund, must not exceed £100 per annum. Forms of application should be obtained forthwith from the Secretary, Epsom College, 49, Bedford-square, W.C.1, and must be returned completed to him not later than May 30th, 1934.

Tuberculosis Scholarships in Rome

The Italian Fascist National Federation against Tuberculosis has placed at the disposal of the International Union against Tuberculosis six scholarships at the Benito Mussolini Institute in Rome. They are each of a value of 6000 lire, plus board and lodging, and are intended to enable foreign medical practitioners to stay at the institute and follow a course of studies. This stage of eight months will correspond with the academic year (from Nov. 15th to July 15th) interrupted by the usual holiday periods.

The scholarships will preferably be awarded to young physicians who are already familiar with tuberculosis problems, and the kind of work undertaken will be subject to agreement with the director of the institute.

Application should be made through the secretary of the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock-square, London, W.C. 1, not later than July 1st.

London School of Hygiene and Tropical Medicine

The 1934–35 course of study at the school, which qualifies students to sit for the University of London diploma in public health, and covers a period of nine months' whole-time work, will begin on Oct. 1st. An open competition will be held on June 28th–29th for the Fishmongers' Company studentship which carries a free place in the course. Applications for this studentship must be sent in by June 18th to the secretary of the school, Keppel-street, Gower-street, W.C.1.

The Langley Memorial prize, of the approximate value of £21, is open to competition amongst officers of the West African medical staff, whether on the active or retired list. The award will be made for the best paper on tropical medicine or surgery; tropical hygiene and sanitation; or tropical entomology and parasitology. Special consideration will be given to original work. Papers must be delivered to the secretary of the school before Oct. 1st.

Royal College of Physicians of Edinburgh

A quarterly meeting of the college was held on May 1st, with Dr. Edwin Bramwell, the president, in the chair. Dr. Francis William Murray Cunningham (Hove, Sussex) was introduced and took his seat as a fellow. Dr. William Lindsay Kinnear (Dundee), Major James Henry Barrett, I.M.S., and Dr. David Rhys Lewis (Swansea) were elected to the fellowship. Dr. Robert Thin was re-elected a representative of the college on the conjoint committee of management of the triple qualification.

It was announced that the Cullen prize had been awarded equally between Sir Frederick Menzies and Lieut.-Colonel A. G. McKendrick.

Medical Tour in Poland

Those joining the medical tour to Poland, which is being arranged by the Royal Institute of Public Health, will leave London on August 2nd, arriving at Danzig on August 6th. A special visit will be paid to Inowroclaw, an inland watering-place with medical baths for dealing with cases of rheumatism, arthritis, and throat disease. On August 7th the party will reach Warsaw, where the hospitals and clinics will be inspected and an opportunity to visit the sanatorium at Otwock will be given. August 8th will be spent in Cracow, and on the 9th there will be a reception by the civic authorities of Gydnia. The party will reach London again on August 13th. Passports will be necessary, but Polish visas will be granted free for this tour. Further information may be had from the secretary of the institute, 23, Queen-square, London, W.C.1.

Research Fellowships in Tuberculosis

The Dorothy Temple Cross research fellowships in tuberculosis for 1934–35 will shortly be awarded by the Medical Research Council. The object of these fellowships is to give special opportunities for study and research to workers who intend to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis. Candidates must be British subjects and must possess suitable medical, veterinary or scientific qualifications, and preference will be given to those who wish to make their studies or inquiries outside Great Britain. The value of the fellowships awarded will depend upon the standing and qualifications of the candidate, but will not be less than £350 per annum, and they will as a rule be tenable for one year, exclusive of allowances. It may also be possible to award a senior fellowship of considerably greater value to a specially well-qualified candidate who wishes to undertake an intensive study of some particular problem of tuberculosis at a chosen centre of work in another country. Further particulars and forms of application are obtainable from the secretary of the Council, 38, Old Queen-street, Westminster, London, S.W.1. Applications must be made by June 1st.

Liverpool Psychiatric Clinic

The annual meeting of this clinic was held on May 7th, with Dr. W. M. Frazer, medical officer of health for Liverpool, in the chair. The speakers were Dr. Doris Odlum, honorary secretary of the National Council for Mental Hygiene, and Dr. S. Barton Hall, an honorary physician of the clinic. Dr. Odlum spoke on mental health and the community, and Dr. Barton Hall described the work of the clinic during the past ten years. It claims to be one of the first, perhaps the first, psychiatric out-patient clinic to be established outside London; it commenced its activities in 1924 thereby antedating the recommendations of the 1930 Mental Treatment Act, with regard to the establishment of out-patient clinics, by some six years. The experience has been that "in a very considerable proportion not only of the psychoneurotic but of the early mental cases, the problem is amenable to skilled psychological handling and a permanent readjustment between individual and environment can be brought about with some rapidity and without having recourse to measures, such as segregation away from home, which the public are still accustomed to regard as severe." It is hoped that in the near future an increase in trained staff will permit of an increase in attendances at the clinic and will also help to meet the ever-growing demand both for individual instruction and for lectures in psychological medicine.

National Temperance Hospital

The eighth annual Macalister lecture will be delivered at this hospital on Thursday, June 21st, at 9 P.M., when Dr. Robert Hutchison will speak on praise and dispraise of doctors.

Ladies' Medical Golfing Society

The spring meeting was held at Oxhey Golf Club on May 4th, 1934. The results were as follows: Canny Ryall Challenge Cup and Memento: Mrs. McCullagh, 75 net. Division I.—Scratch prize: Miss Dix-Perkin and Mrs. Russell Smith tied at 90. Handicap prize: (1) Mrs. Russell-Smith, (2) Mrs. Relph, (3) Mrs. Perry. Division II.—Scratch prize: Lady Goadby, 100. Handicap prize: (1) Mrs. McCullagh, (2) Mrs. Mortimer Woolf, (3) Mrs. Gardiner-Hill tied with Lady Goadby. Best Ball prize: Mrs. Russell-Smith and Mrs. Bain, 78½. 12 Hole Bogey Greensomes: Miss Sheila Dudgeon and Miss Betty Marriage, all square.

Royal Photographic Society Exhibition

The series of photographs by Lieut.-Colonel F. D. S. Fayrer, I.M.S. retd., now on view at the galleries of the Royal Photographic Society in Russell-square, provides an interesting record of a life spent in India. From the unlimited subjects at his disposal Colonel Fayrer has succeeded in presenting in a very attractive way many impressions of the daily life of India, its architecture, and the varying types to be met with amongst its people. One portrait in particular—No. 7, The Old Havildar—bears a striking resemblance to one of our famous literary men. The exhibition will remain open on week-days until May 31st.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, May 15th.

Special Meeting of Fellows, 5 P.M. General Meeting of Fellows, 5.30 P.M.

WEDNESDAY.

Surgery: Subsection of Proctology. 5 P.M. Annual General Meeting. Surgical Treatment of Carcinoma of the Colon. Discussion to be opened by Dr. Fred W. Rankin (Lexington, Kentucky) and Dr. T. de Martel (Paris). Sir Charles Gordon-Watson and Mr. J. P. Lockhart-Mummery will follow.

THURSDAY.

Dermatology. 5 P.M. (Cases at 4 P.M.) Annual General Meeting. Dr. G. B. Dowling: 1. Localised Myxœdema with Hyperthyroidism. 2. Pustular Psoriasis. Dr. F. A. Silcock: 3. Leprosy: Mixed Nodular and Anæsthetic Type. Dr. Hugh Gordon: 4. Sarcoid. 5. Peculiar Form of Urticaria.

Neurology. 8.30 P.M. Annual General Meeting. Pathological Meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, May 14th.—8 P.M., Annual General Meeting. 8.30 P.M., Prof. George E. Gask: Clean Wounds, Ancient and Modern (annual oration).

CHELSEA CLINICAL SOCIETY.

TUESDAY, May 15th.—7.30 P.M. (at the Hotel Rembrandt, Thurloe-place, S.W.), dinner, followed by a discussion on Ophthalmic Notes on the Air Force Pilot Overseas, opened by Squadron-Leader P. C. Livingston, R.A.F.

NORTH-WEST LONDON MEDICAL SOCIETY.

TUESDAY, May 15th.—9.30 P.M. (at the Regal Rooms, Finchley-road, N.W.), Dr. H. Avery: Diagnosis and Treatment of Common Gastric Disorders.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Manson House, Portland-place, W.

THURSDAY, May 17th.—7.45 P.M., Demonstration. 8.15 P.M., Prof. W. Schüffner (Amsterdam): Recent Work on Leptospirosis (lantern slides).

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY, 11, Chandos-street, W.

THURSDAY, May 17th.—8.30 P.M., Dr. Alfred Adler: Presidential Address.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

THURSDAY, May 17th.—3 P.M. (at Manson House, Portland-place, W.), Lord Macmillan: The Professional Mind (Fifteenth Maudsley Lecture).

ROYAL INSTITUTE OF PUBLIC HEALTH.
MAY 15th to 20th.—Congress at Norwich.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, May 14th, to SATURDAY, May 19th.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Course in Psychological Medicine; afternoons.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Course in Dermatology; afternoons and evenings.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Course in Urology for advanced Post-graduates; all day.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W. Lecture-demonstration on Anginal Pain, at 2.30 P.M., on Tues., by Dr. A. E. Clark-Kennedy.—PANEL OF TEACHERS. Individual clinics in various branches of medicine and surgery are available daily. Courses of instruction, clinics, &c., arranged by the Fellowship of Medicine are open only to Members and Associates.

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.

THURSDAY, May 17th.—4.30 P.M., Dr. E. Mapother: Prevention of Mental Diseases.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH, Paddington, W.

THURSDAY, May 17th.—5 P.M., Prof. J. C. Drummond: Vitamins in Relation to Present Day Problems of Public Health.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, May 16th.—4.30 P.M., Mr. Stanford Cade: Radium in Malignant Disease of the Urinary Tract.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

MONDAY, May 14th.—5 P.M., Dr. R. T. Brain: Rodent Ulcer.

WEDNESDAY.—5 P.M., Dr. I. Muende: Essentials of the Pathology of the Skin.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, May 15th.—3.30 to 5 P.M. (at the General Hospital), Mr. A. B. Danby: Pelvic Inflammations of Women.

WEDNESDAY.—4 P.M. (in the Lecture Theatre of the Medical Faculty Buildings), Prof. J. B. S. Haldane: Contributions of Genetics to Medical Science. Second of three lectures.

THURSDAY.—4 P.M. (in the Medical Theatre), Dr. H. Guy Dain: Regulations appertaining to National Insurance Practice (first of two lectures).

FRIDAY.—3.30 to 5 P.M. (at the Queen's Hospital), Prof. Wm. Gemmill: Surgery of the Sympathetic Nervous System.

LEEDS GENERAL INFIRMARY.

TUESDAY, May 15th.—3.30 P.M., Dr. MacAdam: Demonstration of Medical Cases.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, May 15th.—4.15 P.M., Dr. R. S. Paterson: Radiological Investigation of the Spinal Column with special reference to Compensation Work.

GLASGOW POST-GRADUATE LECTURES.

WEDNESDAY, May 16th.—4.15 P.M. (at the Royal Infirmary), Dr. A. M. Crawford: Medical Cases.

Appointments

FARRINGTON, GORDON, M.B. Lond., has been appointed Resident Medical Officer, London Lock Hospital.

FRANKLIN, JOHN L., M.D. Camb., M.R.C.P. Lond., Assistant Physician for Diseases of the Skin, Westminster Hospital.

Certifying Surgeons under the Factory and Workshop Acts: KINGSLEY, A. P., B.M., B.Ch. Oxon. (Burton Latimer, Northampton), and PENMAN, F. V. G., M.B., Ch.B. Glasg. (Dukinfield, Cheshire).

Vacancies

For further information refer to the advertisement columns

All Saints' Hospital for Genito-Urinary Diseases, Austral-street, St. George's-road, S.E.—Res. H.S. At rate of £100.

Ashton-under-Lyne, District Infirmary.—Asst. Radiologist. £300.

Barnsley, Beckett Hospital and Dispensary.—Res. Surg. O. £300.

Bedford County Hospital.—First and Second H.S.'s. At rate of £165 and £140 respectively.

Belgrave Hospital for Children, Clapham-road, S.W.—H.S. At rate of £100.

Birmingham Children's Hospital.—Res. Surg. O., Asst. Res. M.O. £175 and £125 respectively. Also H.P., H.S., and Cas. H.S. Each at rate of £75—£100.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £100.

Bristol City and County.—Asst. M.O.H. £500.

Bristol Dispensary.—Two M.O.'s.

Burton-on-Trent General Infirmary.—Cas. O. and H.P. £150.

Cardiff, King Edward VII. Welsh National Memorial Association. H.P. for Glan Ely Hospital. £100.

City of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.

Dewsbury and District General Infirmary.—H.S. £150.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £150.

Edinburgh City.—Clin. M.O. for Venereal Diseases Scheme. £750.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Jun. Asst. Path. £250. Also H.P., three H.S.'s, and Obstet. Asst. Each at rate of £50. Also Jun. Obstet. Surgeon.

Evelina Hospital for Sick Children, Southwark, S.E.—H.P. At rate of £120.

Fareham, Hants, Knowle Mental Hospital.—Asst. M.O. £550.

Glasgow, Lightburn Joint Hospital, Shettleston.—Res. Phys. £375.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Director of Radiological Dept.

Hospital for Sick Children, Great Ormond-street, W.C.—H.P. and H.S. Each at rate of £100.

Ilford, King George Hospital.—Deputy Res. M.O. £200. Also H.S. £100.

Italian Hospital, Queen-square, W.C.—H.S. At rate of £100.

Lancaster Royal Infirmary.—Jun. H.S. £130.

Lewisham Hospital, High-street, Lewisham, S.E.—H.P. At rate of £80.

Liverpool Eye, Ear and Throat Infirmary, Myrtle-street.—Hon. Ophth. Surgeon.

Liverpool, Royal Southern Hospital.—Hon. Asst. Gynæcologist and Hon. Laryngologist.

Llanelly and District Hospital.—H.S. £150.

L.C.C.—Temp. Visiting M.O. At rate of £100.

London Hospital, E.—Asst. Director of Medical Unit.

London Fever Hospital, Liverpool-road, N.—Two Asst. Phys.

London Jewish Hospital, Stepney-green, E.—Out-patient Asst. £125.

Manchester and Salford Hospital for Skin Diseases.—Asst. M.O. £100.

Miller General Hospital, Greenwich-road, S.E.—Cas. O. and Out-patient O. Each at rate of £150. Also H.P. and H.S. Each at rate of £100.

Oswestry, Robert Jones and Agnes Hunt Orthopædic Hospital.—H.S. At rate of £200.

Preston and County of Lancaster Royal Infirmary.—H.S. £150.

Queen's Hospital for Children, Hackney-road, E.—Surgeon to Ear, Nose and Throat Dept.

Reading, Royal Berkshire Hospital.—Res. Anæsthetist. At rate of £150.

Rochester, St. Bartholomew's Hospital.—Res. Surg. O. At rate of £225.

Rotherham Hospital.—H.P. £180.

Royal Northern Hospital, Holloway, N.—Res. M.O. £370. Also Clin. Asst. for Dermatological Dept.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon Physician.

St. Albans, Hill End Hospital for Mental and Nervous Disorders.—H.P. At rate of £200.

St. Giles' Hospital, Brunswick-square, Camberwell, S.E.—Asst. M.O. £350.

St. Helen's Hospital.—Jun. H.S. £150.

St. Mary Abbots Hospital, Marloes-road, Kensington, W.—Asst. M.O. £250.

St. Mary's Hospital, W.—Cas. H.S. At rate of £100.

Salford Royal Hospital.—Two H.S.'s. At rate of £125.

Sheffield Children's Hospital.—H.P. At rate of £100.

Sheffield, Jessop Hospital for Women.—H.S. to Maternity Dept. At rate of £120.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.

West London Hospital, Hammersmith-road, W.—Hon. Dermatologist. Also Hon. Asst. Anæsthetist.

Wolverhampton Royal Hospital.—H.S. Also H.S. to Ear, Throat and Nose Dept. Each at rate of £100.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Lesmahagow, Lanark.

Births, Marriages, and Deaths

BIRTHS

BATEY.—On May 2nd, at 64, Holland-park, W., the wife of Maurice Batey, L.D.S. R.C.S. Eng., of a son.

TAYLOR-YOUNG.—On May 3rd, at The Red House, Park-lane, Salisbury, the wife of H. S. Taylor-Young, F.R.C.S., of a son.

MARRIAGES

BRANDON—MITCHELL.—On April 30th, in St. Giles' Cathedral, Edinburgh, William J. M. Brandon, F.R.C.S. Eng., to Grizel M. J., youngest daughter of the late J. C. Mitchell, M.B., D.Sc., Johannesburg, and Mrs. Mitchell, Sundial, Gilmerton, Midlothian.

DEATHS

EVANS.—On May 3rd in London, Idris David Evans, M.D., B.S., Barrister-at-Law, Deputy-Coroner for Central London.

KIRK.—On May 3rd, at Southgate, N.14, James Kirk, M.D. (late of Straits Settlements and Bridlington), in his sixty-seventh year.

McCLURE.—On May 3rd, James Campbell McClure, M.D., Chevalier de la Légion d'Honneur, of 65, Wimpole-street, W.1.

TIMMS.—On May 5th, the result of an accident, Samuel Day Timms, L.D.S. R.C.S. Eng.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE THYROID AND LYMPHATIC LEUKÆMIA

THE striking resemblance between the symptoms of hyperthyroidism and of those of chronic lymphadenosis was noted originally in 1924 by G. R. Minot and J. H. Means. Irritability, agitation, hyperactivity, asthenia, increased sweating, and loss in weight, associated with a warm moist skin, a rapid pulse, and fine tremor of the hands, are found in both diseases. In both there is a raised basal metabolic rate, and improvement in both may result from treatment with Lugol's iodine solution. Dameshek, Berlin, and Blumgart have now reported (New Eng. Jour. Med., April 5th, 1934, p. 723) a case of "aleukæmic lymphatic leukæmia" in which apparent recovery followed complete thyroidectomy. The patient was a woman of 42; her spleen occupied almost the entire left half of the abdomen and the glands were also enlarged. The total white cell count was at its maximum 10,000 per c.mm.; the percentage of lymphocytes, most of which were of the immature type, was about 60; and there were about 20 per cent. of blast cells thought to be lymphoblasts. The basal metabolic rate was constantly in the neighbourhood of plus 60. Treatment with X rays and iodine was without effect, but after thyroidectomy the basal metabolic rate immediately fell to normal levels, and the clinical signs and symptoms of hypermetabolism disappeared. The lymph glands and spleen regressed about 90 per cent. from their original size, and all immature cells disappeared from the peripheral blood. The patient said she felt "wonderfully well." The authors recognise that remissions have frequently been reported in lymphatic leukæmia and that the effects recorded here may merely be due to such a remission, but the rapid onset of improvement after operation suggests that thyroidectomy was at least partly responsible.

Those in search of other references to this relationship will find the relevant observations briefly set out in a paper on the influence of the endocrine system in blood disorders by Dr. Douglas Hubble published in our issue of July 15th last year. Hubble concludes that it is a reasonable working hypothesis that the thyroid gland is disordered in chronic lymphatic leukæmia. "This is an assumption," he adds, "which, notably by Friedgood's research, has been brought to the edge of certainty."

NESTS FOR NON-PREGNANT RABBITS

THE private life of the rabbit, like that of Henry VIII, has been known to excite unfavourable comment, but Mr. C. W. Bellerby[1] has recently described a naïve and charming practice of the normal œstrous doe which may be considered creditable. Shortly before parturition the captive pregnant rabbit makes a nest by plucking fur from her breast, abdomen, and flanks and using it to line a hollow in a corner of the cage. Mr. Bellerby, whose laboratory in the department of social biology of University College, London, maintained a colony of 90 isolated, unmated, female rabbits, observed that during the spring the fond creatures were frequently making nests. Pseudo-pregnancy is not unknown in isolated does as a result of spontaneous ovulation, and he thought at first that this phenomenon must be occurring unusually often, but the results of a few post-mortems convinced him that this was not so. He began to watch his rabbits closely: "cages were scrutinised with the utmost care first thing every morning, any nest found being removed after examination." He began his investigation on April 1st, 1932, and narrowly escaped closing it on the same historic anniversary by ceasing observations at midnight on March 31st, 1933.

Among ten animals killed at different times during the year, pseudo-pregnancy occurred in only one, so that clearly most of the does had not even this much excuse for their behaviour. By far the greatest number of nests were made in the spring and none at all in the cold months. Hysterectomy did not check their activities; indeed not only was nesting more frequent in a series of 15 hysterectonised rabbits, but successive nest building by the same doe occurred far more often. About half the normal œstrus females practised nest building. No ovariectomised animal was seen to make a nest, so that ovarian secretion appears to be essential to their development of this instinct; this would account for the seasonal variation, because ovarian activity in the rabbit is greatest in the spring. Hysterectomy has been shown in the rabbit and guinea-pig to prolong the life of the corpus luteum of pseudo-pregnancy; Mr. Bellerby thinks it possible that hyperactivity of the ovary may follow hysterectomy, rendering the doe more sensitive to the stimuli, whatever they are, which provoke nest-building. There is something touching about the whole picture; presumably if Mr. Bellerby's does were human they would run a creche. We learn anyway that "these observations are entirely in accordance with the work of Weisner and Sheard (1933), who have found that maternal behaviour in the rat is not necessarily dependent on the formation of the corpus luteum."

LEWIS'S CATALOGUE OF BOOKS

WE have received from H. K. Lewis and Co., Ltd. (136, Gower-street, London, W.C.1), a second supplement to the catalogue of their Medical and Scientific Lending Library. This covers the years 1931 to 1933 (Price 2*s.*; to subscribers 1*s.*), and along with the first supplement (1928–30) forms a complete guide to the books in the library and incidentally a useful index to contemporary medical literature. For this purpose the value is greatly enhanced by a classified index of subjects, with the names of those authors who have written upon them. The catalogue is a further instalment of the firm's intention, expressed at the opening of their new building three years ago, to make the pathway between the producers and the consumers of books as smooth, as easy, and as inexpensive as possible. The catalogue bound up with both supplements is priced at 16*s.* (to subscribers 8*s.*).

VETERINARY SURGEONS

THE Register of Veterinary Surgeons for 1934 which has just reached us from the Royal College of Veterinary Surgeons (10, Red Lion-square, W.C.1, price five shillings), contains the names of 3379 members, a decrease of 14 on the number for the previous year. The number of students who presented themselves for examination at the College during the year was 898, of whom 57 per cent. satisfied the examiners, and there were 664 individual students examined in the year as compared with 488 in the previous year. The Register contains amongst other things a copy of the by-laws including the provisions of the supplemental charter of May 18th, 1932, which gave the College power to institute new post-graduate diplomas in tropical veterinary medicine and other branches of veterinary science, but in future years a separate volume is to be issued containing the Register only. The standard of production has vastly improved of recent years, and the Register as now issued is pleasing in form and substance.

DEMONSTRATIONS OF CONTRACEPTIVE TECHNIQUE.—On May 16th, at 2.30 P.M., a demonstration will be given by Mrs. Marie Stopes, D.Sc., and Dr. Evelyn Fisher, at the Clinic for Constructive Birth Control, 108, Whitfield-street, London, W. Application for tickets (which will be supplied to medical practitioners only) should be made in writing to the hon. secretary at the clinic.

[1] A Type of Maternal Behaviour in the Normal Œstrous Female Rabbit. By C. W. Bellerby, Quart. Jour. Physiol., 1934, xxiv., 77.

ADDRESSES AND ORIGINAL ARTICLES

MACHAON, OR THE FUTURE OF SURGERY*

By Geoffrey Keynes, M.D. Camb., F.R.C.S. Eng.
ASSISTANT SURGEON, ST. BARTHOLOMEW'S HOSPITAL

Some twelve years ago, while reading Parker's short "History of Surgery in Great Britain," I was struck by the immensely important part that war had played in the development of the craft of surgery. The god-like Machaon, son of Æsculapius, was the first military surgeon who has found a place in literature, his services to the Greek army during the Trojan wars having been celebrated by Homer in the Iliad. Since Machaon's time other surgeons have played their important parts in the unrecorded history of the innumerable conflicts with which humanity has punctuated its progress through the ages, and in historic times a surprising number of the great names in surgery are discovered to have been those of individuals who for a greater or lesser part of their careers were serving the armies of their countries.

Surgery and War

It is unnecessary to enter upon a list of all early military surgeons. Ambrose Paré, taken as the type, was one of the greatest surgeons of all time, and almost the only great surgeon of the sixteenth century, created a revolution in the practice of military surgery. The scales of orthodoxy fell from his eyes when he saw that the condition of the wounded soldiers who had been treated by the surgeons was on the whole worse than those who had not been treated at all. He accordingly abolished the fashionable boiling oil dressing and substituted dry dressings. He reintroduced the use of the ligature instead of the cautery for hæmostasis in amputation. He invented the use of the artery forceps as an aid to the application of the ligature. Paré's great textbook of surgery was translated into several European languages, and was a standard work for the greater part of the seventeenth century. Meanwhile in this country, Woodall, as the result of experience on the field of battle, invented in the early part of the seventeenth century the modern trephine with its centre-bit, and Wiseman, serving with the Cavalier armies during the Civil war, gained the wide experience which enabled him to write his classical "Chirurgical Treatise," published in 1676. Wiseman was the last of the great English surgeons to be trained in war, but in his writings he had laid the foundations on which solid progress could be built. The surgeons of the Napoleonic wars, the Peninsular war, and the Crimean war all added their contributions. Larrey introduced the plaster bandage and the many-tail bandage. Guthrie used the straight splint for fracture of the femur, and practised ligature of both ends of large arteries at the site of injury. Gamgee popularised absorbent and antiseptic dressings. Spencer Wells invented the hæmostatic forceps which bears his name and first used it in the Crimea. During the latter part of the nineteenth century war played a less conspicuous part in the development of surgery, but this brief catalogue of names will help to strengthen the thesis with which I opened my remarks.

The reason why war has exercised so great an influence on the craft of surgery is very plain to see. The earlier surgeons were necessarily occupied largely with the surgery of injuries, with repairing the damage done by arrows, spears, and slings, with amputating limbs, with the treatment of lacerated wounds, and with relieving depressed fractures of the skull. Until the advent of anæsthetics and asepsis, surgery had but small application in civilian practice, and consequently the military surgeons were in the ascendant, and the lines of their advance were limited to those prescribed by the necessities of war.

It is perhaps depressing to reflect that the advance of surgery, the noblest of the crafts, has been so intimately related to the most vicious and cruel of mankind's activities—namely, his desire to destroy his fellow creatures. But it is consoling to realise that the two greatest advances of all, anæsthetics and asepsis, owed nothing to the stimulus of war. Nevertheless it seems to be true to say that the future course of surgery will be largely shaped by events that have only recently taken place, for the reverberations of the greatest war of all have scarcely begun to die down in the world of surgery. I have purposely, therefore, not included the Great War in reviewing the past, for while it adds strength to my thesis it belongs in a surgical sense to the future. We can still hardly guess what will be the ultimate effect on surgery of the million tragedies enacted on the battlefields of France and Flanders. Possibly the surgical millennium will be attained without the necessity for such another cataclysm to stimulate the brains and hands of surgeons to advance their craft, the momentum given by the Great War being sufficient to carry surgery along for many years yet, particularly on certain lines presently to be considered.

Also it seems unlikely that the surgery of injuries, especially of fractures, will soon fall into the background of knowledge. Ever since the war the motor-car has provided a continually increasing number of victims on whom the surgeon may practise his skill, until the number of casualties occurring every year in a large country such as the United States of America exceeds those of any lesser war. These casualties are so scattered that they do not provide the opportunity for mass experience such as results from the organised treatment of the wounded during war, but at least they keep the lamp of knowledge alight—and this is the only crumb of comfort that we can derive from contemplation of what newspapers call "the toll of the road."

The Modern Development of Surgery

Modern surgery has become a technical process so refined in comparison with the rough-and-ready carpentry of our predecessors that some of its practitioners seem inclined to exalt it almost to the position of one of the fine arts. But although the practice of surgery demands the exercise of judgment as much as of skill and a full appreciation of human relationships, yet it contains in it nothing creative, and it remains the noblest of the crafts. Many surgeons are, indeed, in love with surgery, and some seem to feel almost like high-priests officiating at a sacrificial altar. But it is necessary to remember also the feelings of the victims. Very few patients love surgery; all of them, in fact, except a few with psychological abnormalities, hate surgery, and many do not scruple to say so, however grateful they may feel for the benefits they have received. To all but the most educated minds, surgery is only another name for a "cutting operation," and that is a thing engendering the sense of fear. The ordinary mind, therefore, shrinks from surgery, and often puts off invoking its aid until circumstances have forced the issue. It is often the patient, through delay, who is responsible for the failures of surgery, and the real advance of surgery depends almost as much upon the education and collaboration of the patient as upon the technical improvements of the craft. It is evident, therefore, that to the lay mind the apotheosis of surgery will not be the performance of some difficult process requiring exquisite skill and great judgment, but the total abolition of the necessity for any surgery at all. Fortunate it is that the race of surgeons is, on the whole, a race of honest and disinterested men. Their aim is indeed the perfection of technical processes so long as the need for such processes exists; but most do not hesitate also to abandon their operation and their pleasure in its skilful performance when the necessity for it has clearly disappeared. It is only human nature asserting itself if there is a slight lag in this abandonment in the face of the large rewards that even now await the skilful, and, I fear, sometimes the dishonest, craftsman. It may be that the advance of surgery towards its annihilation would be slightly accelerated by the standardisation or abolition of fees for individual operations, but that is a larger question involving social politics. I wish rather to examine the lines upon which surgery is likely to proceed in development as a technical and highly specialised process.

---

* An address delivered to the Royal Medical Society at Edinburgh on Feb. 9th, 1934.

SURGERY AND THE SCIENCES

The rise of surgery during the last 75 years has been so rapid that some of its votaries have become dazzled with their own brilliance. Out of this bedazzlement has repeatedly arisen the announcement that surgery has reached its zenith, and that no further developments of importance are to be expected of it. But any such pronouncement is rash and premature. Who can say what startling innovation may not suddenly arise from advances in the physical sciences, to name only one of the possible sources of benefit to surgery? For many years Harvey Cushing, practising cranial surgery at Boston, regarded a certain form of brain tumour as inoperable owing to the hæmorrhage which would follow its removal. Physical science then introduced the electrical coagulating and cutting current, finely adjustable at will. Soon afterwards Cushing was recalling those of his previously condemned patients who remained alive, in order that he might now safely remove these tumours, while controlling hæmorrhage with the coagulating current. He must have felt almost the same satisfaction as did Paré or Spencer Wells when they first procured hæmostasis by methods which were refinements compared with those of their predecessors. The cutting and coagulating currents are now rapidly coming into use and to some extent displacing "the knife." There are theoretical and practical advantages in sealing the lymphatics and small blood-vessels as the operation proceeds. Time is saved and loss of blood stopped; local dissemination of a cancer by the operation is probably prevented; and it may be safely predicted that electricity will have a considerable part in the future of surgery, for electrosurgery is only in its infancy.

The Legacies of War

This is, however, only an example of an adjunct to surgery drawn from a pure science, and its effect on surgery is indirect. The Great War, as I have already suggested, has left many legacies of surgical value, the end of which cannot be foreseen. The knowledge of fractures and their treatment that we possessed before the war seems now to have been absurdly inadequate. Our standards of results were much too low, our splints were primitive and many of them unmechanical, our methods of treatment much too static. With the innumerable gunshot fractures of the war and with minds like that of Sir Robert Jones to work upon the problems that resulted, a huge body of knowledge and experience quickly accumulated. Older methods and materials were discarded, the principle of traction began to assume its proper place, and a revolution in orthopædics was brought about. It may be said that the force of this war-time change is now spent; yet the post-war period has seen the introduction of novocain anæsthesia in the reduction of fractures, and of the various improvements in methods of fixation used by Bohler and his school. Fracture technique is, in fact, still advancing rapidly both on the continent and in this country. Also it must be remembered that it takes time for a new generation of orthopædic surgeons to arise, surgeons who are fully free to practise the newer methods and to justify them by their results. It may be that the advance in orthopædics will grow slower as the years pass, but it seems unlikely to die away for many years to come. In the meantime orthopædics might seem to be losing almost more than it gains, for few branches of surgery can have suffered more pruning as a result of the activities of the pure scientist and of the Ministry of Health. No longer are our hospitals infested with the victims of rickets and surgical tuberculosis. Heliotherapy and diet factors have dealt severe blows at the orthopædic clinic, and although unemployment has delayed this part of preventive medicine it is only a matter of time until surgery almost ceases to know these preventable diseases.

PLASTIC SURGERY

Another familiar example of the legacies of war is the advance of plastic surgery. Many of the principles had been known for centuries, but never before had there been quite the same pitiful appeal from thousands of the disfigured. It seems likely that here the limits of advance have been comparatively soon reached, and I should not anticipate that the future holds very much more in that direction. Already the sardonic observer may affect to notice a falling-off in the supply of legitimate grist for the plastic mill, and a tendency for it to emulate the mysteries of the beauty parlour. Face-lifting, and operations for the relief of abdominal obesity or for reducing the breasts to the dimensions demanded by the dictates of fashion, these all have their place. Call it æsthetic surgery if you will—it is not the highest form of our craft, but at least it is ministering to the (supposed) needs of one section of humanity. Fortunately the problem of the hare-lip has directed the attention of plastic surgeons to its frequent concomitant, the cleft palate; for there, if anywhere, was a field for gentle persuasion and refined technique, instead of the horrible crushing and mangling of infants that was formerly practised under the protection of the names of Brophie and his followers. The grafting of skin is an everyday affair, and a variety of methods are at our command, including the fascinating process of inlay graft. Even the grafting of a whole cornea has been successfully accomplished. The grafting of organs, even of the smallest, has been hitherto unsuccessful. Attempts have been made with the parathyroid gland, the adrenal gland, and fragments of the thyroid gland, but although temporary effects have been noted while the grafted tissue was undergoing absorption, there is, as far as I know, no proved example of a grafted organ having undergone true growth in its new host. The plastic surgeon may perhaps turn his attention in the future to the extremely difficult technical problems of grafting of organs or even of limbs by means of accurate suture of blood-vessels. We may not expect to see a repetition of the miracle of St. Cosmas and St. Damian when the lower limb of a dead Moor was grafted on to the body of a Christian, but it may well be that the surgery of the future holds some technical surprises of that kind in store.

Probably the science of tissue culture will help to throw some light on the problems involved. Clearly successful grafting depends for its success on many factors controlling growth and repair of which we have but the foggiest understanding at the present time. Tissue culture is the only line of research which is likely to help in this direction, and it may indeed prove of unexpected service to surgery in general, for every surgical operation is an experiment testing the capacity of the body for carrying out repairs, and some of our failures may be due to our ignorance in this branch of biological science.

The Growing Edge of Surgery

Any mention of the legacy of war must lead us inevitably to what is at the present moment the most conspicuous "growing edge" of surgery—namely, the surgery of the thorax. With knowledge of the treatment of gunshot wounds of the thorax came a rapid advance in the general surgery of the thorax, though this is restricted for the most part to dealing with the thoracic wall and the lungs. Assaults are continually being made upon what are almost the last strongholds of the body, the mediastinum and the heart itself, but progress here is slow. Cutler's experiments in endocardiac surgery seemed ten years ago to be about to blossom and bear fruit; but the disconcerting discovery followed that the mitral stenosis which the division of the sclerosed valves was designed to relieve was responsible only in a minor degree for the patient's disabilities. Usually the heart muscle was irretrievably damaged by toxic poisoning, so that the successful performance of an ingenious and dangerous operation produced little or no improvement in the few patients that survived. Also one of these few patients, after living a few years, recently died from other causes, and it was found at the post-mortem examination that actually the valves never had been cut at all. Many attempts have been made to treat carcinoma of the œsophagus in the mediastinum; but the operative mortality remains in the neighbourhood of 100 per cent. Surgery must expect to receive an occasional set-back of this kind, and the bolder spirits will not be discouraged. For instance, Prof. Grey Turner, of Newcastle-on-Tyne, has recently recorded the successful extirpation of a carcinomatous œsophagus with subsequent provision of a new external channel, formed partly of a tube of skin and finished off with a short length of small intestine, through which the patient is now merrily swallowing beef-steaks and beer. It may be taken as a general axiom in the march of surgery, that "the nearer the heart the slower," but it is within the thorax that some of the most important hopes for the future of surgery lie. It was at one time thought that the thorax would yield its secrets as readily as the abdomen had done, but it is being realised that the physiology and mechanics of the thorax are much more obscure, and that surgery in the thorax will always have to work on a narrower margin of safety than in the abdomen. No facile analogy between the two will really represent the facts. The thoracic surgeon to attain full competence will have to add familiarity with the use of the bronchoscope and œsophagoscope to his repertory, and to be in the fullest sympathy with the problems confronting the anæsthetist. Already lobectomy for bronchiectasis is becoming an operation of repute, and further developments will surely follow.

THE SYMPATHETIC SYSTEM

Another conspicuous point in the growing edge of surgery is the surgery of the sympathetic system. It is interesting to note how from small beginnings made a few years ago, a considerable body of valuable observations has now been accumulated—although the foundations were laid largely on fallacies! It is generally realised now that Leriche's operation of peri-arterial sympathectomy and Royle's operation of ramisectomy for spastic limbs were based on faulty premises and observations. Yet the work of these pioneers has borne excellent fruit, and to-day, as a result of advances made with the help of the anatomist and physiologist, the various forms of ganglionectomy constitute an important branch of surgery which is certain to develop further in the future.

The foregoing are examples of something that will be added unto surgery, probably in the near future. But, taking the long view, it seems probable that in the end surgery will be gradually shorn of many of her glories, and will ultimately have to take a back seat as an unimportant branch of something else. A considerable part of my personal interests centre in the surgery of the thyroid gland, but I recognise that the thyroid harvest will not be gathered for ever. When a fuller elucidation of the pathology of simple and toxic goitre and the relationship of the thyroid to the other endocrine glands has been achieved, it is likely that surgery will be almost entirely eliminated. At the present moment the thyroid surgeon can in a short time virtually cure the majority of his patients with toxic goitre, because he is able to snap suddenly one of the most important links in the vicious circle that maintains the disease. The patient is not really cured by this rather savage form of treatment, but is enabled to live at so different a level from what she was at before that she is "cured" by comparison. It is improbable that in 50 years' time anything so crude as surgery will be used to relieve the endocrine complex known as toxic goitre. Total thyroidectomy is now being practised for the treatment of heart failure: I cannot regard it as an advance in surgery.

The Cure of Cancer

That is perhaps only a small and simple example of what is going to happen to surgery. The obvious and larger problem is what relation will the surgery of the future bear to the greatest of all human scourges, cancer. So large a proportion of surgical activity is taken up with cancer that its removal from the sphere of surgery would cause an enormous hole in the surgeon's day. Moreover, it appears to me that if this is ever to happen at all it will happen suddenly, and surgery may be caught unawares and find herself smiting at a vacuum. It seems fairly clear that the cancer problem is a biological one connected with an abnormality of growth or with a process of repair gone mad. It is a loss of control of cell division, which can be initiated by the action of specific chemical substances. So precise has knowledge on this point recently become that pure chemical compounds have been synthetically produced, which can be made to cause a carcinoma or a sarcoma in an animal in a given time almost with complete certainty. These substances have complicated molecules, always containing the benzine ring, and have actually been made from other compounds which occur in the human body. The cancer problem is therefore partly a biochemical one, and the process of experimental cancer production is so nearly perfected that the successful reversal of the process may not be so far distant as we are often inclined to suppose. Surgery can often deal successfully with the primary cancerous growth when it is accessible. It is by the inaccessible parts of the disseminated disease that we are so constantly defeated. Cancer disseminates by the circulation, whether it be by blood-vessels or lymphatics, and perhaps it is by the same route that it will ultimately be attacked, particularly if a biochemical cause leads to the discovery of a biochemical cure. The "cancer cure," in fact, if and when it arrives, may be applied *through the circulation, and since all forms of cancer* appear to be closely related the same principle will apply to all of them. Once, therefore, the goal is reached a large part of surgery as we know it may be rapidly eliminated, and the surgeon be replaced as far as cancer is concerned by the vein-puncturing expert. Those surgeons who are sufficiently adaptable may be able to add the biochemical method to their repertory, for after all it will still be the surgeon who will make the diagnosis and have much of the responsibility for the treatment of the patients. Those who cannot so adapt themselves will have to rejoice with the rest of mankind as best they may, though finding a large part of their occupation suddenly removed.

It may be a long time yet before this desired consummation is achieved. But even in the meantime surgery is finding that gradual encroachments are being made on the cancer field, which was so peculiarly hers. I have borne some part myself in aiding and abetting this encroachment so that perhaps I am a biased witness; but it seems clear enough to me that radiology has virtually abolished pure surgery in cancer of the tongue, mouth, and pharynx, in cancer of the skin, anal orifice, and cervix, and in rodent ulcer. I hold unorthodox and perhaps unacceptable views on the value of radium in carcinoma of the breast, for as far as I am concerned the use of radium, or of radium combined with conservative surgery, has almost eliminated the radical operation. But this view, right or wrong, is at any rate an indication of the trend of events, that is, a gradual narrowing of the surgical circle which until recently so completely surrounded the Tree of Cancer. Radiology has at present scarcely any application in cancer of the alimentary tract, but this process of encroachment will not stop, and perhaps in the end it will be the radiologists and not the surgeons who will receive the rudest shock from the cry that "Cancer is Conquered."

There can be few departments of surgery in which technical refinement, both diagnostic and operative, has advanced more in recent times than in cranial surgery. It seems unlikely that the future will see further rapid strides, and even if it does, cranial surgery is but a relatively small department of the craft. It is highly specialised and can never be the concern of more than a few surgeons at any one time. It demands, however, the very highest type of practitioner. He must bring to his surgery a profound knowledge of physiology and neurology. He must be diagnostician as well as craftsman, and it is all these qualities which we shall demand of the few that we shall deem worthy in the future to practise surgery on our heads. This is indeed the ideal for all surgeons, to be as well versed in the science of their craft as in its technical performance, and it may be that, as surgery becomes a more restricted field, a higher and higher general standard will be expected.

Anæsthetics

The ordinary person's horror of "the knife" is equalled, and frequently exceeded, by the same person's horror of the anæsthetic. Already, if only the ordinary person could be made to realise it, most of the terrors of anæsthesia have been dispelled. The ordinary person's horror is made up of a conviction that she (though often he) will never wake up again, of a fear that the operation will be begun before she is unconscious, of memories (if there has been a previous experience) of the rubbery smell of the mask and of the feeling of suffocation and helplessness when the thing is on the face, of the smell and taste of ether, and, lastly, of the misery of vomiting and coughing with a painful abdominal wound. Modern methods of anæsthesia have already gone a long way towards eliminating these various sources of unhappiness in the patient. The use of the different narcotic drugs, such as nembutal, avertin, and sodium evipan, have made it unnecessary for any patient to know anything about the process of induction of anæsthesia. The use of local anæsthesia, spinal anæsthesia, and gas-and-oxygen have, at any rate in my own practice and doubtless in that of many others, largely eliminated ether and chloroform. It cannot be too widely known that both these drugs are to be regarded as poisons, particularly to the liver, and there can be no question to my mind that they should be encouraged gradually to drop out of use.

Often it is urged that it is wrong to use these improved methods in the teaching hospitals because when the average student gets out into the world and becomes the average practitioner he will find that circumstances force upon him the use of the older, and sometimes the simpler, methods. To some extent this is true, and it is undoubtedly the duty of the medical schools to teach *all* methods. But equally it is the duty of the medical schools to be in the van of progress, for only by the education of the young can general standards be raised in the long run. The student must always be shown the best, so that his almost inevitable fall into the rut of complacent routine may be delayed as long as possible. Education must be keyed up to the liveliest minds, not keyed down to the dullest in the matter of anæsthetics as in everything else. Thus, and thus only, will progress in the general world of surgery be accelerated. The effect of it is everywhere to be seen in the continually improving equipment of hospitals, great and small, throughout the country, and in better knowledge of how to use it for the advantage of the ordinary patient. The surgery of the future must seek to temper the wind more and more to this same ordinary patient. The surgeon will think less of his own prowess and more, ever more, of the sufferings of the patient. Even so familiar a thing as post-anæsthetic vomiting will not be taken as a matter of course, because it is nearly always avoidable. Progress in surgery implies not only increased technical proficiency on the part of the surgeon, but less pain and greater safety for the patient. It is clear that the anæsthetic question is closely bound up with this, and so good a beginning has been made with the methods I have mentioned that further improvement is bound to follow. Knowledge on the part of the patient that anæsthesia has no terrors makes for confidence. Confidence produces increased willingness in the patient to coöperate, and so leads directly to earlier diagnosis, earlier treatment, and better results. I therefore believe most firmly that the future of surgery lies to an important extent in the hands of the anæsthetists, and so of the chemists and pharmacologists to whose researches the whole of our recent progress in this line is primarily due.

I have indicated one or two major directions in which surgery in the future is likely to be curtailed. It is possible to enumerate many minor fields in which the same process is visible. Already the syringe has eliminated a great deal of minor surgery, such as most of the operations that used to be done for varicose veins and internal hæmorrhoids. The holocaust of tonsils still goes on, but there are signs that even here a change is beginning to appear, and it is not impossible that improved hygiene or the science of endocrinology, or both together, may eventually eliminate a large part of the lymphoid surgery that employs so many hands so profitably at the present time. The abdominal tonsil, on the other hand, shows no sign of a decline in popularity. The causes of appendicitis I believe to be many, and that anyone who thinks it will be prevented by dieting, or by regulation of the bowels, or by any one measure, is likely to be disappointed.

In many provinces of surgery there is that mysterious pendulum which swings so relentlessly to and fro. It is swinging at the present moment against the surgery of the upper abdomen in the treatment of gastric and duodenal ulcer, and no doubt it will in due course return as the tide of perforations and relapses after medical treatment begins to rise again. The time, so much desired, when the ætiology of ulcers is so well understood that they can be prevented seems still to be distant, and knowledge of how to treat them is therefore still essential. It is difficult to see how surgical ingenuity can devise many more variants of operative treatment, but the surgeon of the future may have formed a clearer idea than we have at the present moment as to exactly which is the best procedure to adopt—gastro-enterostomy, pyloroplasty, gastro-duodenostomy, partial gastrectomy, excision of the ulcer, and so forth.

The Follow-up System

Clear ideas, however, can only be attained by the acquisition of a large body of accurate statistical evidence, and this brings me to the mention of an important influence on the future trend of surgery which is certain to gain in strength as time passes—namely, the "follow-up" method of investigation. Surgery in the past has too often been content to muddle along without any clear guidance from the proved evidence of results. At the same time members of the surgical profession have often expressed discontent with the attitude shown by official scientific bodies, especially by the Royal Society, towards surgery. They have seemed to deny to surgery any scientific status, and I doubt whether even now our profession appreciates the underlying reasons for this. I am afraid the scientist has only too much grounds for regarding the surgeon as a skilled carpenter, as a man who likes carrying out experiments on the human body, but is not interested in the results. This attitude is the absolute negation of the scientific method, and is partly the cause and partly the effect of the chief weakness of many surgeons, that is, their great confidence in their own opinions. Most surgeons will deny that they are indifferent to the results, or alternatively plead that there is no time in the surgeon's day for the following-up of patients. This plea may excuse but does not justify indifference to scientific method; it merely shows the necessity for better organisation of surgical practice. The "follow-up" departments which are appearing in many centres, will, I believe, make a very big contribution to the progress of surgery, and tend to remove the aspersion on the surgeon of an unscientific approach to his problems. Erroneous "impressions" formed by individuals will be replaced by wider and more accurate information based on the histories of patients for a long period after their operations. Survival rates for a minimum of five years after treatment will be an essential basis for assessing the success or failure of any method used in the treatment of cancer. At the present time very few surgeons know even the number of recurrences that take place after their operations for hernia. Many of them believe there are no recurrences, but this is merely an agreeable ignorance of facts which can only be ascertained by a "follow-up" department. It is true that the compilation of statistics introduces a new difficulty—that of their interpretation, but I do not believe that it is beyond the wit of man to overcome this difficulty with thought and experience. Also the follow-up principle does not depend solely on statistical information for its value. If it compels the surgeon to see his patients at intervals for a long time after treatment, and to know beyond a shadow of doubt when they are dead, it will have performed a useful function. The scientific surgeon of the future will not depute his follow-up work to a junior assistant, but will see his successes and his failures with his own eyes. He may sometimes be a sadder and a wiser man, but at least he will be better able to interpret his statistics intelligently and to know when he is being misled by the pure statistician.

Standardisation and Mass Production

The general trend of human affairs at the present time is set strongly towards standardisation and mass production. Both eugenic principles and political theory favour the production of a standard man, and the time may come when all except standard men will be thrown away, a few non-standard individuals being kept, perhaps, as material for research. Surgery has hitherto kept its status as a pure handicraft—aided, it is true, by an increasing number of instruments of precision, but a handicraft it remains, aloof from politics, apart from the industrial revolution and mass production. But can we be sure that this blessed state can be indefinitely maintained? Does not a glimpse into the future induce a nightmare vision of standard operations being performed by machinery on standard men? This would tend to eliminate automatically those individuals not conforming to the standard, and so to accelerate the realisation of the eugenic ideal. Perhaps it might be permissible to offer in special circumstances and at an enhanced price an old-fashioned operation performed manually and finished with a special hand-sewn scar. Fortunately it seems to be impossible that anything so awful can ever take place, and the surgeon may look forward to a long-continued demand for the sheer skill of his naked hands (naked except for rubber gloves) in the service of suffering humanity.

I have necessarily given a very superficial survey of the future of surgery for the field is so wide and the possibilities so great. But it is wholesome occasionally to stop and survey the situation, even superficially, and think whither it may be leading us. It may be true that consideration of the past and how we got here is more valuable than speculation on the future. It is certainly true that the past does shed much light on the conduct of the present, and it should correct all those who through ignorance of the past, through an overweening complacency in their own achievement, or through an inability to realise that methods and ideas quite unknown to them can be of value, assert that no further technical advance in surgery can take place. The statement has been made at intervals and always it has been falsified, and I have tried hard myself to avoid giving any such impression. Perhaps I have conveyed the idea that the field of surgery will always grow narrower, but that is because I lack the imagination to be able to foretell what additions to the surgeon's repertory will be made. It is undeniable that subtractions are continually occurring and yet surgical activity increases rather than diminishes. Probably this is due to increased facilities for surgery, better diagnosis, and the better education of the people in surgical matters. It is, I think, certain that contraction will eventually occur, as preventable disease is eliminated and as earlier diagnosis renders surgery less and less necessary. The enthusiastic surgeon may console himself with the thought that congenital defects (in spite of eugenics) and accidents will always remain, whatever else may be taken from him. There may, alas, even be another war to which he will look to provide fresh impetus for the development of his craft, when the force of the Great War has expended itself. But even there lurks disappointment, for the next war may not be so much a war of wounds as the last one. Death will be dealt out in more insidious ways, and surgery may not be called upon to perform so many of her wonders. Destruction will be more complete, and will be carried far beyond the front line of the combatants, so that most of the surgeons may be themselves dead or out of action. Machaon will look less god-like in a gas-mask, and he will carry in his hand a hypodermic syringe and ampoules of antibacterial serum rather than a scalpel.

Surgery as a Science

You may have perceived that I have spoken through most of this address of surgery as the term is generally understood, that is, as a handicraft; but I have protested against the attitude of surgeons who choose to stand aloof from science and so tend to tie their profession down to the status of refined carpentry. I feel sure, however, that I have given to surgery a narrower sense than it will come to hold in the future, and than it already does hold wherever surgery is most alive, for as time passes it will draw nearer to the status of an applied science. To achieve this the surgeon will coöperate more and more closely with medicine and with biological and biochemical science. Examples of this tendency can be seen to-day in many fields of surgery, such as the thyroid gland and other endocrine glands, the central nervous system, the sympathetic nervous system, the urinary system, and so on. We have heard a great deal in recent years of the value of team-work, and this has not been entirely lip-service to an ideal. The pure scientist may at any moment stumble on facts related to surgery, and if these teams exist, surgery may receive unexpected advancement. Only the other day I was shown at the Cancer Hospital a series of mice which had been the subject of experiment in connexion with the genesis of cancer. Who could have foretold that œstrin, a crystalline hormone extracted from the urine of mares, would, when painted on the skin of a male mouse, produce enlargement of the prostate and the development of large inguinal hernias? Yet such is the extraordinary fact, and, irrelevant as it may seem, it may lead in directions of importance to surgery. It is impossible to foretell exactly how this balance between surgery and the allied sciences is to be achieved, but at least it must not be said that the surgeon has remained indifferent to any discovery, of whatever nature, that might lead to the advancement of his craft. The trend of events shows that the surgical mind can possess the qualities of sympathy and collaboration, and whatever the future may hold it is safe to assert that never was surgery in general more living than it is at the present moment. We may be forgiven if we believe that this is the golden age of surgery, for, after all, it is the present, not the past or the future, in which we live.

THE HORMONES AND THEIR CHEMICAL RELATIONS *

By E. C. Dodds, M.V.O., M.D., D.Sc., F.R.C.P. Lond.

COURTAULD PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF LONDON; DIRECTOR OF THE COURTAULD INSTITUTE OF BIOCHEMISTRY AT THE MIDDLESEX HOSPITAL

LECTURE III

The application of the study of organic chemistry to the internal secretions of the thyroid itself has proved so successful that the hormone has now been synthesised. Since, however, this work is well known, it will only be necessary to give a few of the more important landmarks.

Discovery of Thyroxine

It will be remembered that the thyroid gland was the first organ to which could be attributed an internal secretion. The classical writings of Sir William Gull in 1874 described the condition of myxœdema in great detail and laid great emphasis on the thyroid atrophy. Three years later Ord (1878) confirmed these observations and suggested the name—myxœdema. In 1895 Kocher demonstrated the relationship between natural myxœdema and that following thyroidectomy. It was also shown that post-operative myxœdema responded to treatment by the administration of thyroid gland.

The next important stage was the discovery of iodine as a constituent of the thyroid gland. It was put forward as a suggestion by Kocher in 1895 that normal thyroid gland might possibly contain iodine, since he had shown that iodine had a profound influence upon the morphology and activity of the organ. Tschirch (Kocher, 1895) attempted the search for this element, but entirely failed. The proof that the thyroid contained iodine was given by Baumann (1895), who continued his work until he isolated a protein which he termed iodothyrine. This substance contained iodine and possessed distinct physiological activity as studied upon thyroidectomised animals and myxœdematous human beings. Quantitative studies showed that the compound was more active weight for weight than thyroid gland, and that the iodine content was considerably increased.

From this time onwards a series of very elaborate

---

* The Goulstonian lectures for 1934, delivered before the Royal College of Physicians of London on March 6th, 8th, and 13th. Lectures I. and II. appeared in our last two issues.

chemical experiments were performed and various protein-like concentrates were obtained which were claimed to represent the actual internal secretion of the thyroid in a pure state. It will not be profitable to review all this work, but to jump to the year 1915 when the publication of Kendall's well-known experiments resulting in the discovery of the true internal secretion of the thyroid appeared (Kendall, 1915). The process resulting in the separation of this compound was extremely complicated and the yields very poor. The essential part of the manufacture consisted in a hydrolysis of the gland with barium hydroxide solution. So poor was the yield, that starting with over a ton of thyroid he obtained relatively few milligrammes of the active body. The formula $C_{11}H_{10}O_3NI_3$ was allotted to the compound in view of its percentage composition. Kendall maintained that the compound was an iodine derivative of an indol compound, but that has since been disproved and it will be unnecessary to consider it.

The crystalline compound isolated by Kendall was very soon found to be the most potent substance for raising the basal metabolic rate of any hitherto described, and it was only natural that severe competition ensued between clinicians and organic chemists for the few milligrammes of this body that were available. Until an adequate method for the preparation of thyroxine in large quantities could be obtained, no progress of any sort could be expected.

The next advance was made by Harington (1926) who, in 1926, described a new method for the isolation of thyroxine from the thyroid gland and one which gave a very much better yield, thus enabling a detailed study of the constitution of this interesting substance to be made. A long series of experiments proved that Kendall's ideas as to the constitution were incorrect, and that thyroxine was a derivative, not of tryptophane, but of tyrosine. Harington was able definitely to establish the constitution and to prove that thyroxine has the formula seen in Fig. 16. Still later, with Barger, he was able to synthesise the substance (Harington and Barger, 1927).

When injected subcutaneously or intravenously in minute doses, thyroxine is capable of raising the basal metabolic rate of experimental animals and of human beings. It will also completely relieve the symptoms of myxœdema. Its activity, however, when given by mouth is very slight owing to its great insolubility, and one must conclude that very little is absorbed.

Substitutes for Thyroxine

In view of our interest in synthetic substances it is necessary to consider certain other iodine-containing compounds present in the thyroid gland. One of these is di-iodo-tyrosine (Fig. 17). This compound appears to be completely inactive when administered in a similar manner to thyroxine. In so far as is known this substance is not a normal constituent of food, and therefore must be synthesised in the body—possibly in the thyroid. Harington suggests that it may represent a stage in the synthesis of thyroxine.

Another interesting compound is a derivative of thyroxine—namely, 3 : 5-di-iodo-thyronine (Fig. 18). This compound does not appear naturally in the thyroid in so far as is known, but can be made relatively easily in the laboratory. Gaddum (1927–28 and 1929–30) has observed that this compound possesses definite activity of the same type as is displayed by thyroxine. He found that the activity, as measured by acceleration of metamorphosis of tadpoles, was about *one-fifteenth* the activity of thyroxine ; whilst the effect of oxygen consumption of rats was about one-fortieth of that of thyroxine. In a recent paper by Anderson, Harington, and Murray Lyon (1933) clinical experiments with this compound were described. The desirability of using it is indicated by its relatively much greater solubility in water than thyroxine, and hence the possibility of its activity when given by the oral route. They were able to show that this compound when administered in doses of 50 to 75 mg. daily was capable of relieving all the symptoms of severe and well-established myxœdema. In all cases the basal metabolic rate was restored to normal and the characteristic myxœdematous appearance vanished. They justly concluded that this compound could replace thyroxine in every way, and that since it is readily obtainable by synthesis in a pure state, there is every reason to hope that eventually its use will entirely replace that of thyroid extract which, even at the best of times, is only capable of extremely rough standardisation. These workers do not discuss in any detail the reason for the similarity of activity between thyroxine and 3 : 5-di-iodo-thyronine. They suggest that perhaps this compound is transformed in the body into thyroxine itself. The interest from our point of view however lies in the fact that they have shown that the thyroid lock may be picked by a skeleton key. If we contrast the two formulæ it can be seen that they are relatively near to each other in structure, and all that is required is the introduction of two iodine atoms into the 3′ : 5′ position. However, the phenomenon is precisely the same as in the œstrin substitutes, but in the latter case the similarity between the natural substance and the skeleton key is by no means so close.

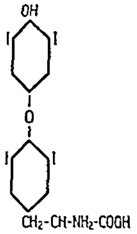

FIG. 16
Thyroxine.

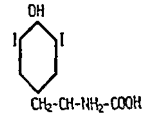

FIG. 17
Di-iodo-tyrosine.

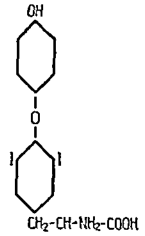

FIG. 18
3 : 5-di-iodo-thyronine.

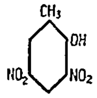

FIG. 19
4 : 6-dinitro-o-cresol.

It will be remembered that in discussing the significance of the activity of the œstrin substitutes the idea that they were converted in the body into œstrin did not appear to be justifiable, particularly when one bears in mind that this conversion, if it occurs at all, would occur in the body of the ovariectomised animal. If any organ were to be responsible for this conversion, one would have thought that the ovary was the most likely. In the same way one would also have thought that the thyroid gland would have been the seat of the conversion of 3 : 5-di-iodo-thyronine into thyroxine. Since, however, this compound is active in cases of myxœdema with presumably little or no functioning thyroid, it would appear that the same arguments apply in this problem as in the substitutes for œstrin.

Where do Hormones Act ?

Hitherto we have considered only the actions of these hormones and their substitutes upon surviving animals, and in order to introduce the next type of synthetic substance it will be necessary for a brief period to consider the actual site of action of these hormones. If we take one of the apparently simpler examples—namely, the action of insulin—it appears at first sight that insulin reduces the blood-sugar by increasing the oxidation of this substance in the body. This theory was held as a theoretical conception before insulin was isolated, and it was therefore with great surprise that no action of the then new hormone insulin could be demonstrated on either glucose solutions or on isolated tissues.

It is well known that thanks to the methods of Warburg (1926 and 1928) it is possible to work out the metabolism of slices of surviving tissue using some 10 mg. or so, and by the adoption of manometric methods the oxidative process of the tissue may be investigated. Very roughly it may be stated that this includes the breakdown of carbohydrate by two entirely distinct methods. The first is by a process known as respiration in which the glucose is burned to carbon dioxide and water; this we know to be controlled by an organo-metallic catalysis process of which the metal is iron and the catalyst most probably a hæmatin derivative. The second process is one known as glycolysis in which the carbohydrate is converted to lactic acid; this may occur both aerobically and anaerobically. These two systems are quite separate but bear a certain quantitative relationship to one another.

If we take a tissue slice and add insulin to it, and measure the metabolism continuously by the methods of Warburg, it is not possible to demonstrate any change whatsoever. It is also very strange to recount experiments with thyroxine. The addition of thyroxine to such a tissue slice will not produce any increase in either respiration or glycolysis, no matter how much thyroxine be added. We are here faced with a very complex problem in that insulin and thyroxine when injected into intact animals will produce profound modification of the carbohydrate metabolism and total metabolism respectively, and yet are completely without activity on the isolated tissue slice. It is indeed unfortunate that no explanation can as yet be advanced to explain this difficulty. There are of course a few examples of hormones that will act upon the isolated organs, for example oxytocin and adrenaline, yet it must be remembered that a surviving uterus possesses an elaborate arrangement of sympathetic nerves, whilst a spiral cut from an artery which can be made to contract by adrenaline also possesses a highly organised structure. Yet it can readily be proved that the respiration and metabolism of these tissue slices in the Warburg manometric apparatus are capable of responding to various chemical agents. For example, the addition of methylene-blue will cause a marked increase in respiration, and the same may be said of other compounds such as the naturally occurring pyocyanine and also the synthetic pyocyanine.

Action of the Nitrophenols

I propose to discuss a compound which possesses the unique quality of acting, not only on the body as a whole, but also on the tissue slice. This compound, 4 : 6-dinitro-o-cresol, possesses the formula shown in Fig. 19 and belongs to the group of polynitrophenols.

It has been known since the year 1885 that certain nitrophenols possessed a marked influence on metabolism; this was shown first by Cazeneuve and Lépine (1885). They were able to show that certain nitrophenols were toxic, and when injected in small and repeated doses death occurred with hyperpyrexia.

Little attention appears to have been paid to this important problem until the year 1928, when a series of experiments were commenced in Heymans's laboratory in Ghent (Heymans and Bouckaert, 1929; van Uytvanck, 1931; Moraes and Casier, 1933). Heymans and his collaborators were able to show that 2 : 4-dinitro-phenol was capable of causing death from hyperpyrexia in pigeons and dogs when administered in small doses at daily intervals, and that before the rise in temperature there was a very marked rise in the oxygen consumption.

In 1932 Plantefol and his collaborators published an extensive work on the pharmacological activity of 2 : 4-dinitro-phenol (Plantefol et al, 1932). In this important publication will be found the full pharmacological details of the action of 2 : 4-dinitro-phenol. They were able to show that the compound raises the basal metabolic rate in all animals whether injected subcutaneously or given by mouth. They also proved that the compound increased the respiration of yeast cells. In the final paper in this monograph they demonstrated the fact that only those nitrophenols which possessed two nitro groups in a position corresponding to the 2′ : 4′ were active. Other dinitro- or polynitro-phenols appeared to have the reverse effect.

Last year Cutting, Mehrtens, and Tainter (1933) published an account of the uses of dinitrophenol for the purpose of stimulating human metabolism, particularly with a view to producing a reduction in weight. They repeated the earlier experiments of Heymans, Plantefol, and others, and they were able to confirm that the administration of the compound to animals resulted in an immediate rise in basal metabolic rate. When daily doses of 3 to 5 mg. per kg. of body-weight were given to patients the basal metabolic rate rose rapidly to about +40 per cent. and remained at this level for as long as it was administered. As soon as the drug was withheld the basal metabolic rate fell to normal. They were interested solely in the treatment of obesity and their conclusions are that the compound is quite safe to use for a reduction in weight.

Work has been in progress in my laboratory for a considerable time on this problem and many polynitrophenols have been tested. Together with Sir William Pope (Dodds and Pope, 1933) I was able to demonstrate that 4 : 6-dinitro-o-cresol was many times more potent than 2 : 4-dinitro-phenol, and that its immediate toxicity to animals was of about the same order as the dinitrophenol. The various nitrophenols were investigated by administering them either by subcutaneous injection dissolved in sesame oil or by oral administration to guinea-pigs whose basal metabolic rate was followed by means of the technique described in the study of the thyrotropic hormone.

A typical example of the increase in oxygen consumption is shown in the following experiment. The basal oxygen consumption of the guinea-pig in question was found by the method already referred to, to equal 0·0135 c.cm. oxygen per gramme of guinea-pig per minute; the temperature of the animal at this stage was 97° F. Eight milligrammes of dinitro-o-cresol were dissolved in sesame oil and this was administered by subcutaneous injection. One hour afterwards the oxygen consumption had risen to 0·0376 c.cm. per minute and the temperature had increased to 100·9° F. Four hours later the temperature had reached 102·8° F., whilst the oxygen consumption had increased to 0·0460 c.cm. per gramme of guinea-pig per minute. The exactly similar experiment with 2 : 4-dinitro-phenol produced a rise of about one-fourth of the magnitude.

CLINICAL EXPERIMENTS

We concluded that dinitro-o-cresol was a much more suitable substance than dinitrophenol for clinical experimentation, since weight for weight it is many times more potent, and appeared to be of about the same order of toxicity. Together with Robertson (Dodds and Robertson, 1933[1]) I therefore proceeded to investigate the effects of this compound upon normal human beings.

The first series of experiments here outlined were those in which 3 mg. per kg. of body-weight were given. This caused alarming increases in the basal metabolic rate, from a normal of −5 to +70 in five days in one case, and from −10 to +100 in another. On withdrawing the drug the metabolic rate fell rapidly and within four days after the administration was discontinued the basal metabolic rate was down to normal.

A series of very interesting toxic phenomena were found when the basal metabolic rate rose above +50. The patients were uniformly restless and uncomfortable and suffered from severe attacks of sweating. Strange to say they were drowsy during the day and restless at night, the disturbed nights being mainly due to the great increase of sweat. Some patients suffered from severe headache, and all showed a slight lemon yellow pigmentation of the sclerotics and the skin. A very careful investigation of the blood and urine was performed when this pigmentation was at its height, but no evidence of excess of bile-pigments or their derivatives could be discovered in either blood or urine. The temperature was only slightly increased even when the basal metabolic rate was increased to +100. The patients also suffered from loss of appetite and felt very depressed and miserable.

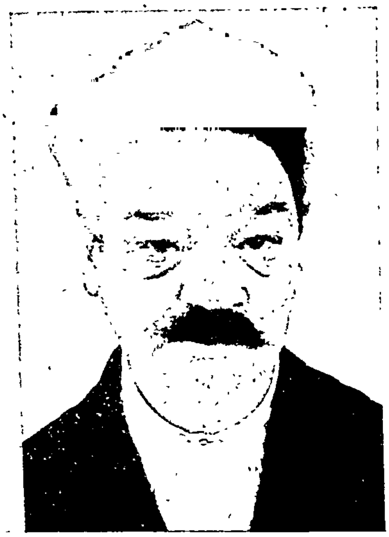

FIG. 20.—B.M.R. raised to + 20 by dinitro-o-cresol. Myxœdema unrelieved.

One of the most striking points about this elevation of the basal metabolic rate was that it was unaccompanied by a corresponding increase of pulse-rate or those changes which have been described by Read (1922) occurring in hyperthyroidism. This was the first indication to us that the action differed very considerably from that of thyroxine. We were able to obtain another striking demonstration of the difference between the action of thyroxine and dinitro-o-cresol, since we were able to observe its effect on a case of myxœdema (Dodds and Robertson, 1933 [2]).

The subject was a man, aged 42, who had had well-marked myxœdema and had been attending hospital for some three years. It had been found necessary to administer 2 grains of thyroid (B.P., 1932) daily in order to maintain the basal metabolic rate within normal limits and to keep him free from symptoms and signs of myxœdema. The administration of thyroid extract was stopped and the symptoms of myxœdema were allowed to develop. At this stage the basal metabolic rate as determined by the Benedict-Roth apparatus was −18. In the first place he was given daily doses of dinitro-o-cresol at the rate of 3 mg. per kg. of body-weight—that is to say the same amount that produced a rise of roughly +100 per cent. in three or four days in normal persons. The basal metabolic rate rose sharply from −18 to +73 per cent. and again the same toxic symptoms were observed—namely, lethargy during the day and intense perspiration during the night, loss of appetite, and general discomfort. The drug was discontinued and the basal metabolic rate fell rapidly to −18.

This observation proves conclusively that the myxœdematous person, with presumably no functioning thyroid tissue, responds as well to the action of this drug as does the normal person. In the second series of observations, sufficient quantity of the drug was administered daily to keep the basal metabolic rate well above normal, and it was found that in this case 100 to 150 mg. per day administered by mouth enabled him to maintain the basal metabolic rate at +20. Although his basal metabolic rate varied between +20 and +30 per cent., his myxœdema was unaffected as can be seen by the picture (Fig. 20), which shows the stigmata of the disease very clearly.

We have here, therefore, a very interesting spectacle of a myxœdematous patient with a basal metabolic rate of between +20 and +30, thus indicating that thyroxine does not relieve the symptoms and signs of myxœdema by merely raising the basal metabolic rate. The drug was then withdrawn and the basal metabolic rate fell to −18; thyroid was then administered until the basal metabolic rate was maintained at between 0 and +10 per cent. The symptoms of myxœdema disappeared in a very short time, and the next picture (Fig. 21) shows the patient again with a basal metabolic rate of +10 with all his symptoms of myxœdema cleared up. It is important to bear in mind that the first photograph, showing the symptoms and signs of myxœdema obviously present, was taken when his basal metabolic rate was +20 to +30 per cent.

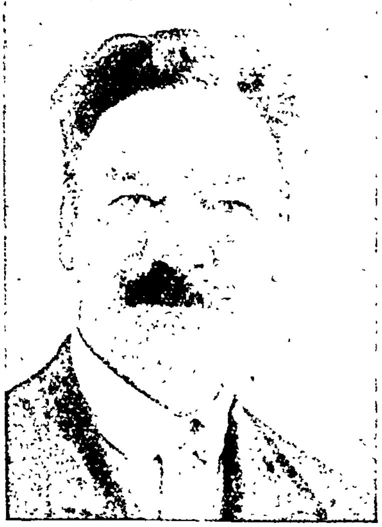

FIG. 21.—B.M.R. raised to + 10 by thyroid. Myxœdema completely relieved.

These experiments prove conclusively that we are here dealing with an entirely different mechanism and that a depression in basal metabolic rate bears no relation to myxœdema, nor, alternatively, will an artificially raised basal metabolic rate clear up the symptoms, and that therefore thyroxine must act in a manner quite apart from its mere stimulation of metabolism.

RESPIRATION OF ISOLATED TISSUES

There is one final difference between the action of dinitro-o-cresol and thyroxine that I have to bring to your notice. It will be remembered that I have already called attention to the fact that naturally occurring hormones will not act upon isolated tissues, and that however much thyroxine be added to a surviving slice of tissue, it is impossible to demonstrate any increase in the oxidation by the method of Warburg. In my laboratory Greville and I (Dodds and Greville, 1933) have been able to show that the reverse obtains with dinitro-o-cresol. The measurements were made in the Haldane-Barcroft-Warburg period to consider the actual site of action of these hormones. If we take one of the apparently simpler examples—namely, the action of insulin—it appears at first sight that insulin reduces the blood-sugar by increasing the oxidation of this substance in the body. This theory was held as a theoretical conception before insulin was isolated, and it was therefore with great surprise that no action of the then new hormone insulin could be demonstrated on either glucose solutions or on isolated tissues.

It is well known that thanks to the methods of Warburg (1926 and 1928) it is possible to work out the metabolism of slices of surviving tissue using some 10 mg. or so, and by the adoption of manometric methods the oxidative process of the tissue may be investigated. Very roughly it may be stated that this includes the breakdown of carbohydrate by two entirely distinct methods. The first is by a process known as respiration in which the glucose is burned to carbon dioxide and water; this we know to be controlled by an organo-metallic catalysis process of which the metal is iron and the catalyst most probably a hæmatin derivative. The second process is one known as glycolysis in which the carbohydrate is converted to lactic acid; this may occur both aerobically and anaerobically. These two systems are quite separate but bear a certain quantitative relationship to one another.

If we take a tissue slice and add insulin to it, and measure the metabolism continuously by the methods of Warburg, it is not possible to demonstrate any change whatsoever. It is also very strange to recount experiments with thyroxine. The addition of thyroxine to such a tissue slice will not produce any increase in either respiration or glycolysis, no matter how much thyroxine be added. We are here faced with a very complex problem in that insulin and thyroxine when injected into intact animals will produce profound modification of the carbohydrate metabolism and total metabolism respectively, and yet are completely without activity on the isolated tissue slice. It is indeed unfortunate that no explanation can as yet be advanced to explain this difficulty. There are of course a few examples of hormones that will act upon the isolated organs, for example oxytocin and adrenaline, yet it must be remembered that a surviving uterus possesses an elaborate arrangement of sympathetic nerves, whilst a spiral cut from an artery which can be made to contract by adrenaline also possesses a highly organised structure. Yet it can readily be proved that the respiration and metabolism of these tissue slices in the Warburg manometric apparatus are capable of responding to various chemical agents. For example, the addition of methylene-blue will cause a marked increase in respiration, and the same may be said of other compounds such as the naturally occurring pyocyanine and also the synthetic pyocyanine.

Action of the Nitrophenols

I propose to discuss a compound which possesses the unique quality of acting, not only on the body as a whole, but also on the tissue slice. This compound, 4 : 6-dinitro-o-cresol, possesses the formula shown in Fig. 19 and belongs to the group of polynitrophenols.

It has been known since the year 1885 that certain nitrophenols possessed a marked influence on metabolism; this was shown first by Cazeneuve and Lépine (1885). They were able to show that certain nitrophenols were toxic, and when injected in small and repeated doses death occurred with hyperpyrexia.

Little attention appears to have been paid to this important problem until the year 1928, when a series of experiments were commenced in Heymans's laboratory in Ghent (Heymans and Bouckaert, 1929; van Uytvanck, 1931; Moraes and Casier, 1933). Heymans and his collaborators were able to show that 2 : 4-dinitro-phenol was capable of causing death from hyperpyrexia in pigeons and dogs when administered in small doses at daily intervals, and that before the rise in temperature there was a very marked rise in the oxygen consumption.

In 1932 Plantefol and his collaborators published an extensive work on the pharmacological activity of 2 : 4-dinitro-phenol (Plantefol et al, 1932). In this important publication will be found the full pharmacological details of the action of 2 : 4-dinitro-phenol. They were able to show that the compound raises the basal metabolic rate in all animals whether injected subcutaneously or given by mouth. They also proved that the compound increased the respiration of yeast cells. In the final paper in this monograph they demonstrated the fact that only those nitrophenols which possessed two nitro groups in a position corresponding to the 2′ : 4′ were active. Other dinitro- or polynitro-phenols appeared to have the reverse effect.

Last year Cutting, Mehrtens, and Tainter (1933) published an account of the uses of dinitrophenol for the purpose of stimulating human metabolism, particularly with a view to producing a reduction in weight. They repeated the earlier experiments of Heymans, Plantefol, and others, and they were able to confirm that the administration of the compound to animals resulted in an immediate rise in basal metabolic rate. When daily doses of 3 to 5 mg. per kg. of body-weight were given to patients the basal metabolic rate rose rapidly to about +40 per cent. and remained at this level for as long as it was administered. As soon as the drug was withheld the basal metabolic rate fell to normal. They were interested solely in the treatment of obesity and their conclusions are that the compound is quite safe to use for a reduction in weight.

Work has been in progress in my laboratory for a considerable time on this problem and many polynitrophenols have been tested. Together with Sir William Pope (Dodds and Pope, 1933) I was able to demonstrate that 4 : 6-dinitro-o-cresol was many times more potent than 2 : 4-dinitro-phenol, and that its immediate toxicity to animals was of about the same order as the dinitrophenol. The various nitrophenols were investigated by administering them either by subcutaneous injection dissolved in sesame oil or by oral administration to guinea-pigs whose basal metabolic rate was followed by means of the technique described in the study of the thyrotropic hormone.

A typical example of the increase in oxygen consumption is shown in the following experiment. The basal oxygen consumption of the guinea-pig in question was found by the method already referred to, to equal 0·0135 c.cm. oxygen per gramme of guinea-pig per minute; the temperature of the animal at this stage was 97° F. Eight milligrammes of dinitro-o-cresol were dissolved in sesame oil and this was administered by subcutaneous injection. One hour afterwards the oxygen consumption had risen to 0·0376 c.cm. per minute and the temperature had increased to 100·9° F. Four hours later the temperature had reached 102·8° F., whilst the oxygen consumption had increased to 0·0460 c.cm. per gramme of guinea-pig per minute. The exactly similar experiment with 2 : 4-dinitro-phenol produced a rise of about one-fourth of the magnitude.

CLINICAL EXPERIMENTS

We concluded that dinitro-o-cresol was a much more suitable substance than dinitrophenol for clinical experimentation, since weight for weight it is many times more potent, and appeared to be of about the same order of toxicity. Together with Robertson (Dodds and Robertson, 1933 [1]) I therefore proceeded to investigate the effects of this compound upon normal human beings.

as 3 : 5-di-iodo-thyronine and the various phenanthrene and di-benzanthracene derivatives, it is incapable of replacing the activity of the natural substance. These latter require either the intact animal, or at least part of the intact animal, and therefore must act in an entirely different manner. It is hoped that these observations will concentrate the attention of workers on the fundamental problem of the action of hormones.

To many it would appear that the isolation of the hormone represents the be-all and end-all of the experimentalist's aim and object. Yet we know that unless the actual mechanism of action is understood, we only understand one fraction of the problem. Until we can find out where the hormones act and explain why dinitro-o-cresol will act upon an isolated tissue slice whilst thyroxine is without action, we cannot claim to have progressed very far in the study of these phenomena.

The Mechanism of Simmonds's Disease

Let us now return to our starting-point—namely, Simmonds's disease. Here we see that a destruction of the anterior lobe of the pituitary causes degeneration of the thyroid, the ovaries and testes, the pancreas, the suprarenal, and possibly the parathyroids. We have only studied in any detail the gonadotropic hormone (prolan) and the thyrotropic hormone, and we have seen that these hormones of unknown constitution and protein character cause the organs mentioned above to produce substances that are capable of being attacked by the organic chemist.

I cannot here consider in any detail the adrenotropic hormone which has been described by Collip, Anderson, and Thomson (1933). They showed that in hypophysectomised animals definite changes in the suprarenal gland could be seen and these could be prevented by the administration of extract of anterior lobe.

Anselmino, Hoffmann, and Herold (1934) have confirmed this work, and they have also been able to demonstrate similar alterations in the pancreas and in the parathyroid glands of hypophysectomised animals, and that these changes could be prevented by the administration of a suitable extract (Anselmino, Herold, and Hoffmann, 1933,[1 2]; Anselmino and Hoffmann, 1933).

We are now in a position to understand the mechanism of Simmonds's disease. Perhaps the accompanying diagram will go some way towards clearing up and sorting out this elaborate tangle of hormones (Fig. 22). We can see in it hormones acting upon the thyroid, gonads, suprarenal, pancreas, and parathyroid. Remember that these hormones are of the protein character and at present of unknown constitution, and it must be admitted that even the great advances in the study of organic chemistry are not yet adequate to deal, either from the analytical or the synthetic point of view, with these compounds. The respective organs mentioned above, when activated by the anterior lobe, produce their respective hormones which, with the exception of the pancreas, are clear-cut chemical entities which have yielded their secrets of constitution to the art of the organic chemist; their structure is also shown on this diagram.

Together with these formulæ appear the graphic formulæ of a series of skeleton keys which are capable of opening the lock equally well, and at one side of thyroxine and 3 : 5-di-iodo-thyronine, under adrenaline, will be found two skeleton keys—namely, ephedrine and tyramine, both of which appear to act in the same way as adrenaline.

The final column running transversely across the diagram has been labelled Pass Keys. In this group of compounds are found substances which will open more than one biological lock. Under the sex hormones we find the two carcinogenic hydrocarbons, 1 : 2-benzpyrene and 5 : 6-cyclopenteno-1 : 2-benzanthracene which, in addition to causing malignant disease when applied to the skin, are also capable of producing œstrus; here we also find calciferol or vitamin D which can protect against rickets and at the same time will produce œstrus if given in sufficient quantities. Included in this category is 4 : 6-dinitro-o-cresol under the heading of the thyroid secretion. This will perform part of the functions of the thyroid hormone, yet will not protect against myxœdema; on the other hand it will stimulate the metabolism of the tissue slice.

In general it would appear that the anterior lobe of the pituitary produces hormones of extreme complexity belonging to the protein class which act upon organs such as the thyroid, suprarenal, testes, and ovaries, which in turn produce hormones which have yielded their secrets to the organic chemists. These in turn may be imitated by similar compounds manufactured entirely in the laboratory without any connexion with any biological material. There still remains a very large section of the chart to fill in.

Conclusion

The first Goulstonian lecture was delivered in the year 1639, but to a biochemist the lectures for the year 1831 are amongst the most interesting. Exactly 103 years ago, at about this time of the year and in the same theatre, Dr. William Prout delivered three Goulstonian lectures before Sir Henry Halford, the then president, and the censors. It is safe to say that Dr. Prout was one of the first physicians to realise the importance of chemical knowledge in relation to medicine. In the first place he possessed an excellent knowledge of the advanced organic chemistry of the day, and was the first to apply this knowledge in detail to problems of animal and human metabolism. There can be little doubt that Dr. Prout's writings formed one of the major stimuli to Liebig.

It would take too long even to summarise the important researches of this distinguished Fellow of the College. Intimately concerned as he was in the controversy concerning Dalton's theory, he found time to establish beyond all doubt and in the face of the bitter opposition of Claude Bernard, the identity of hydrochloric acid as a normal constituent of the gastric juice. It is interesting to note the tone of his lectures. To the present-day reader, accustomed to the highly technical scientific papers, the writings of the period we are discussing are very involved, and the meanings are frequently wrapped up in elaborate phraseology. This philosophical method of approach to medical and scientific problems was, however, the order of the day. It must be remembered also that the great science of organic chemistry had only just been founded, and it was all but impossible to believe that the organic chemist would solve the composition of the most complex compounds in nature. Bearing this in mind, we can well understand the warning that Prout gives to his audience in the first Goulstonian lecture. He warns them against expecting too much from the chemist, and he remarks that "he (the chemist) will soon discover, for example, that nature will not permit him to officiate as her journeyman, even in the most trifling degree" (Prout, 1831). I trust that the evidence I have brought forward will convince you that even so discerning a prophet as Dr. William Prout took too gloomy a view of the future of chemistry as applied to medicine.

I record with pleasure my indebtedness to those who have kindly read through the manuscript of these lectures and have suggested improvements and corrections: Mr. J. W. Cook, D.Sc., Prof. E. L. Kennaway, F.R.S., Mr. W. Lawson, and Dr. J. D. Robertson. To Miss M. I. Powell I owe a very great debt for her care and trouble in the preparation of these lectures.

LEICESTER ROYAL INFIRMARY.—The annual report of this hospital fills an octavo volume of 360 pages. In 1933 admissions numbered 7069; the children's hospital received 1319 patients. There were 13,250 new out-patients and 20,592 casualties. Traffic accident cases numbered 1313, all but 40 of which were motor casualties. Of this total 296 cases were admitted; they spent 6557 days in hospital and cost £2850. For the third time in the last 16 years income met expenditure; the total income of £86,452 provided a credit balance of £30. The infirmary now possesses nearly half a gramme of radium element, which cost £6922. The Leicester and County Saturday Hospital Society is equipping Overstrand Hall, Cromer, as a home for female patients, and it will be opened at Whitsuntide. The erection of a home for men in the grounds will then be begun. Consequential changes will eventually liberate 50 beds for women and 60 for men.

THE CLINICAL INVESTIGATION OF STAPHYLOCOCCAL TOXIN, TOXOID, AND ANTITOXIN

By H. J. PARISH, M.D., M.R.C.P. Edin.
R. A. Q. O'MEARA, M.D. Dub., F.R.C.P. Irel.
AND
WINIFRED H. M. CLARK, B.Sc. Edin.

(From the Wellcome Physiological Research Laboratories, Beckenham, Kent)

THERE is a wide difference of opinion concerning the use of such measures as vaccine therapy, chemotherapy, and the administration of yeasts in the prophylaxis and treatment of boils and other staphylococcal diseases (vide Hallam, 1932); in general the results have been disappointing, and some other adjunct to surgery is clearly called for. Recently investigations have been made of the rôle of circulating antitoxin in affording protection against natural and experimentally induced infection, and concentrated antitoxic sera have become available for therapeutic purposes. Staphylococcal toxoid has also come into clinical use experimentally. The purpose of this paper is to describe a few experiments we have carried out with staphylococcal toxin, toxoid, and antitoxin, and, by correlating this work with observations which have been made in Australia, Canada, and Germany, to draw attention to some of the *immunological problems which still await* elucidation, more especially on the clinical side. Hitherto comparatively little has been done by pathologists in this country.

STAPHYLOCOCCAL TOXINS: PREPARATION AND POTENCY

Toxins have been prepared from a number of strains on Burnet's 0·8 per cent. agar medium to which Parker's 2 per cent. buffered broth (modified) has been added after 48 hours' growth (Parish and Clark, 1932). For assessing the value of our experimental toxins we have used skin neutralisation tests in the guinea-pig, and hæmolytic *titrations using* rabbit corpuscles, the potency in each case being *expressed in terms of the amount of a laboratory* standard serum "K," which has completely neutralised 1·0 c.cm. of toxin. Technical details of the hæmolytic test are discussed later in this paper.

Lightly coloured variants of *Staphylococcus aureus*, Wood 46, which was isolated in Australia from a case of extensive infected burns, have consistently produced good toxin in our hands; 1·0 c.cm. of each of eight successive batches of toxin has required for its neutralisation between 0·04 and 0·13 c.cm. of standard serum K, both in vivo and in vitro. These strains have been largely used for the preparation of toxin and toxoid for immunisation. Lightly coloured variants of other *aureus* strains have *also produced* better toxins than the parent cultures. For example, 1·0 c.cm. of toxin, *prepared from* a *culture* isolated in Sweden from an infected arm associated with vaccination, was equivalent to 0·003 c.cm. of serum K by guinea-pig intracutaneous test and 0·0025 c.cm. by hæmolytic test, whereas 1·0 c.cm. of toxin from a lightly coloured variant of this culture neutralised 0·01 c.cm. of serum K by both tests. In our series there has been no relationship between the potency of the toxin prepared by our method and the clinical severity of the condition from which the strain has been isolated; we have failed completely to prepare good toxin even from the Bundaberg strain which was responsible for the deaths of 12 children from staphylococcal septicæmia in 1928. A similar observation has of course been made in diphtheria, for it is well known by immunologists that strains of *Corynebacterium diphtheriæ* isolated from clinically severe and fatal cases are often of low toxigenicity under the conditions in which potent toxins are usually prepared in the laboratory.

The guinea-pigs "intradermic value," and the hæmolytic value using rabbit corpuscles as determined by combining power, have always approximated to one another, irrespective of the potency of the toxins. Titrations with sheep corpuscles have, however, sometimes given entirely different readings. Neisser and Wechsberg (1901), Bigger, Boland, and O'Meara (1927), and Gross (1932), amongst others, have commented on the differences in hæmolytic titre obtained with the blood of different animals, and Glenny (unpublished) is at present engaged in a special study of the different toxic constituents concerned and their corresponding antibodies. At this stage of the investigation the worker in the clinical laboratory, who is limited in the scope of his inquiry and in the numbers of toxins and sera at his disposal, should confine himself solely to titrations with rabbit cells. He will then have much less difficulty in deciding upon the end-point, and will not be handicapped, as in titration with sheep cells, by having to pay attention to the phenomenon of "hot-cold" lysis (Bigger, Boland, and O'Meara, 1927; Bigger, 1933).

PREPARATION OF STAPHYLOCOCCAL TOXOID

The toxoid has been prepared by adding 0·5 per cent. of formalin to the culture filtrates and incubating for 3 to 14 days at 37° C. to detoxicate. As a preliminary to investigating the antigenicity of the toxoid in laboratory animals or man, tests have always been carried out to ensure absence of toxicity and retention of combining power.

TITRATION OF STAPHYLOCOCCAL ANTITOXIN (ANTIHÆMOLYSIN)

We have already indicated that the antihæmolytic titre, when rabbit corpuscles are used, is a useful measure of antitoxic content. Since the titration of the antihæmolysin present in a patient's serum may furnish valuable information of his response to active immunisation with toxoid or passive with antitoxin, we give our technique in some detail.*

The reagents required include (*a*) our "standard" staphylococcal toxin, B.8750, (*b*) our "standard" staphylococcal antitoxin K, (*c*) rabbit red blood corpuscles (R.B.C.), thrice washed in normal saline, and re-suspended in saline—2 per cent. of "packed" R.B.C.—made up fresh each day, (*d*) the patients' sera, and (*e*) normal saline. It is sufficiently accurate to use dilutions of toxin and serum, prepared on a 50 per cent. difference scale. Two pipettes should be specially marked and set aside for use only with (*a*) undiluted standard toxin, and (*b*) undiluted standard serum respectively. They should on no account be used for any purpose other than measuring undiluted standard toxin and serum. It is advisable to use a separate pipette for each patient's serum, and all pipettes should be thoroughly washed out after use.

The minimum hæmolytic dose (M.H.D.) of standard toxin B.8750 has been determined by mixing in a series of tubes (*a*) a series of toxin dilutions showing 50 per cent. differences, 0·5 c.cm. to each tube, (*b*) 0·5 c.cm. saline, and (*c*) 1·0 c.cm. of 2 per cent. washed rabbit R.B.C. Readings have been made after 1 hour at 37° C., the end-point being the last tube to show complete hæmolysis; from this, the M.H.D. of the toxin can readily be calculated. Since the R.B.C. of different rabbits show individual variation in their resistance to hæmolysis, it has been customary to take the average end-point of a number of titrations as the true M.H.D. of standard toxin B.8750. On this basis, 2 M.H.D. of this toxin are contained in 0·5 c.cm. of a dilution of 1 in 20. When this dilution is used, the end-points of the antihæmolytic titres of sera undergoing test remain constant from day to day. The explanation is that, in titrations involving the neutralisation of toxin by antitoxin, R.B.C. added to the mixtures act solely as an indicator to detect the presence of uncombined toxin.

The method of setting up the titrations of the antihæmolytic power of sera is as follows: In each row of tubes are mixed together (*a*) a series of serum dilutions showing 50 per cent. differences, 0·5 c.cm. to each tube, and (*b*) 0·5 c.cm. of toxin B.8750, diluted 1 in 20. Five minutes later 1·0 c.cm. of 2 per cent. washed rabbit R.B.C. is added, and the contents of the tubes are again thoroughly mixed. After 1 hour at 37° C. the tubes are once more inverted to mix the contents, and then removed from the water-bath. The unhæmolysed R.B.C. are given an opportunity to settle, and the results are then read—usually after one to two hours. If desired, readings may be made after standing overnight, when the end-point will be the same as when readings are taken after a shorter interval (this is only of general application when rabbit R.B.C. are used in the titration). The end-point we have taken is the last tube to show complete absence of hæmolysis—i.e., complete neutralisation of the toxin.

In every series of tests of this type it is important to include a "standard" antitoxin as control. Our "standard" serum is conveniently represented by the symbol K, indicating that it is a constant. Since it is considerably more potent than samples of human serum, it is diluted 1 in 100 as a preliminary to titration on a 50 per cent. difference scale. The results of titrations of patients' sera are expressed as decimal fractions of serum K, never in terms of a variable such as M.H.D. of toxin. The outstanding advantage of this method of expressing the results is that, as soon as an official standard serum is adopted, the potency of sera titrated by this technique will be capable of being expressed in terms of the official standard.

CIRCULATING ANTITOXIN IN "NORMAL" ANIMALS AND MAN

Since Neisser and Wechsberg (1901) first demonstrated the presence of natural antibody in the sera of "normal" laboratory animals and human subjects, a number of workers have made confirmatory observations. The results of our titrations, using as the test toxin our standard toxin B.8750, are given in Table I.

TABLE I

Circulating antitoxin (antihæmolysin)—"normal" sera

—	Sera examined.	Antitoxin as decimal fractions of "standard" serum K.						
		0–0·003	0·007	0·01	0·02	0·03	0·05	0·07
Rabbit ..	100	88	2	7	1	2	0	0
Guinea-pig .	50	41	0	2	2	5	0	0
Horse ..	50	1	7	11	5	18	6	2
Human ..	100	31	34	30	4	1	0	0

This shows a wide variation in the antihæmolytic titre of different animals and men. A similar observation has been made by Bryce and Burnet (1932), who have also shown that about 50 per cent. of 61 normal rat sera which they examined contained demonstrable antitoxin. That so many animals of different species have appreciable amounts is not surprising in view of the widespread distribution of the staphylococcus.

---

* A memorandum giving full details of the technique of titrating the antihæmolysin in human serum was prepared in these laboratories and distributed at the January meeting of the Association of Clinical Pathologists.

CIRCULATING ANTITOXIN IN HUMAN DISEASE BEFORE TREATMENT WITH TOXOID OR ANTITOXIN

A number of papers, giving the results of titrations, have recently appeared in Australia, Germany, and Canada, but there has unfortunately been no common standard of reference, and the method of expressing the values, usually in terms of arbitrary "units," has made it difficult to compare the results obtained in different countries—hence our insistence earlier in this paper that values should be stated in terms of a serum which can later be linked up with an official standard serum. In Australia, Bryce and Burnet (1932) and Connor and McKie (1933) have shown that the antihæmolytic titre is slightly above "normal" in cases of sycosis and other superficial infections; although not markedly raised in patients with boils, it may be very high when carbuncles are present; it is considerably above "normal" in deep-seated infections such as osteomyelitis, and the highest titre recorded was in a case of pyæmia. Very similar findings have been published in Germany by Gross (1933). Once again titres were hardly appreciably raised above the "normal" level in patients with boils and other superficial infections; moderately high titres were recorded in carbuncle, acute osteomyelitis, and purulent arthritis of the knee-joint; the highest titres were in cases of chronic osteomyelitis and perinephritic abscess. Gross has also stated that the presence of antilysin in serum has helped to some extent in the recognition of staphylococcal infection and in appreciating its intensity. In Canada, Dolman (1933) found that the titres in patients with boils were no more and often less than those in "normal" subjects, but he is in agreement with the Australian and Canadian workers that deep-seated infections of bone and muscle give rise to very high titres.

We have not ourselves had an opportunity of titrating large numbers of sera from human patients, but the few titrations we have made with sera from cases of superficial boils and pustular acne have shown considerable variations in titre. Similar differences in titre have, however, occurred in normal individuals.

ACTIVE IMMUNISATION WITH TOXOID

Our experiments in animals have confirmed the observations of others that the amount of circulating antitoxin can be increased by the injection of either toxin or toxoid intracutaneously, subcutaneously, or intravenously. In Table II. are given the titres of the serum of rabbits and human subjects before and after subcutaneous injections of toxoid prepared from the Wood 46 strain.

TABLE II

Immunisation with toxoid, injected subcutaneously

Rabbits.	Total volume injected in c.cm.	Antitoxin as decimal fractions of standard serum K.		Period of observation in weeks.
		Before immun.	After immun.	
1–6	5–8	< 0·003	0·01–0·02	4
7	5	0·01	0·07	
8	8	0·01	0·16	
9	8	0·01	0·16	
Human subjects.		*(Boils and other superficial infections.)*		
1	0·4	< 0·003	0·02	3
2	5	< 0·003	0·03	23
3	4	< 0·003	0·03	18
4	0·35	< 0·003	0·37	4
5	5	0·01	0·02	21
6	5	0·015	0·07	21
7	1·3	0·02	0·05	3

immun. = immunisation.

In a recent paper by Connor and McKie (1934) it is stated that the average titre of circulating antihæmolysin of a group of rabbits rose from nil to 1 in 245 following immunisation with crude toxoid. When concentrated toxoid, which is known to cause less reaction in human subjects, was injected into another group, the rise in titre was less marked—viz., from nil to 1 in 145. A third group injected with vaccines prepared from toxigenic staphylococci (unphenolised and unheated) showed a slight but still appreciable rise (from nil to 1 in 42), which may possibly in part explain the good results that sometimes follow the therapeutic use of vaccines. Our experiments have confirmed Connor and McKie's conclusions that crude toxoid is an efficient antigen.

Some of the human subjects in our series had suffered from furunculosis for some years, and had recently had one or more boils when the course was commenced; a few of our patients have ascribed the rapid disappearance of their boils to the injections. The initial dosage in this and a later group now being immunised has been 0·05 to 0·1 c.cm. of toxoid B.8300. Injections have been repeated at intervals of 4 to 7 days, the volume being increased, in the absence of reaction, in 3 or 4 injections up to 0·75 c.cm. Rather severe local reactions have been encountered in some patients, but others have tolerated 1·0 c.cm. of toxoid without discomfort, a dose which is not, however, recommended for routine use. Dolman (1933) has reported an alleviation of symptoms coinciding with the increased titre of antihæmolysin during immunisation. The rise was more pronounced where the lesions were deep-seated, in which case the titres before treatment were also higher than in patients with more superficial infections. It is possible that here we are dealing with a "secondary stimulus" response. Probably the mechanism is also at work in human subject No. 4 (Table II.), in whom the injection of only 0·35 c.cm. of toxoid has resulted in more than a hundredfold increase in circulating antitoxin. In such a subject in whom the antitoxin-producing mechanism appears to respond to a minimal stimulus, it is easy to imagine a very marked rise in antitoxin following the injection of vaccines containing only traces of toxin or toxoid. A "secondary stimulus" response has also been noticed by us in rabbits which have previously been immunised with toxoid and then allowed to rest for some months. Connor and McKie's series (1934) included 18 cases of sycosis, a condition with little tendency to spontaneous cure; in 10 there was disappearance of the lesions, and in 4 others marked improvement. In a patient with carbuncle who had a relapse, the titre which had risen from 26 to 830 "units" had fallen again to 225.

Further evidence that active immunisation with toxoid protects against infection can be deduced from animal experimentation. We have injected cultures of the Bundaberg and Wood 46 strains of staphylococcus intradermally into normal and immunised guinea-pigs and rabbits, and found a very high degree of resistance to pyogenic lesions in the skin of the immunised animals. Immunised rabbits too have survived the intravenous injection not only of many lethal doses of toxin, but also of culture; in certain instances the immunised animals have been alive and well after two months, although so high a degree of protection is unusual. In one such experiment (Table III.) the course of the septicæmia has been followed, counts having been made of the numbers of staphylococci which appeared on plates inoculated at intervals with two drops of blood.

In both immune and normal rabbits there has been a rapid fall in the number of organisms present in the blood, but the immunised animals have shown a diminution in the degree of the septicæmia at an earlier period than in the case of the control group. Post-mortem examination of the control rabbits revealed large engorged kidneys from which films showed pus and staphylococci; in one rabbit numerous small abscesses were present, especially in the renal cortex. All the experiments carried out with actively immune animals suggest that circulating antitoxin is of value in combating infection with virulent staphylococci.

TABLE III

Living culture, Wood 86 strain (20,000 million organisms) injected intravenously into rabbits immunised with toxoid

PASSIVE IMMUNISATION WITH ANTITOXIN

As with active so with passive immunisation. Rabbits, guinea-pigs, and mice can readily be protected by means of antitoxin against many lethal doses of toxin, but protection against virulent culture has in general been much less complete, the immunised animals eventually dying in most instances from pyæmic infection.

A protection experiment with potent concentrated antitoxin has recently been carried out on eight groups of four mice, 32 animals in all, using 0·6 c.cm. of a 10,000 million suspension of living virulent culture, injected intraperitoneally, as the infecting dose. Four control animals died within 24 hours, and four mice, which had received 0·05 c.cm. of serum subcutaneously seven hours before the culture injection, survived for 48 hours. With increasing doses of serum the period of survival of the groups of four mice increased, until, of the last three groups which had received 0·6, 0·8, and 1·0 c.cm. of serum respectively, three mice were still alive after one month, and 10 had lived for longer periods than 10 days.

The results of a passive protection experiment in rabbits have shown that, while control animals died as a rule in 6 to 16 hours, 11 animals which had had varying amounts of serum intravenously immediately before the intravenous injection of virulent culture survived from 4 to 30 days. Another group of six rabbits which had been injected with antitoxin intravenously 24 hours before the virulent culture in the same experiment showed even better protection, for five were still alive and well after one month. It has been rare in our experiments to get protection as complete as in this experiment.

Closely analogous results have been obtained in hæmolytic streptococcal infections in the rabbit (Parish and Okell, 1927). They showed that rabbits can be protected by antitoxic serum against acute toxæmic death following the intravenous injection of large doses of living culture of hæmolytic streptococci, but that in most instances the surviving rabbits develop arthritis towards the end of the first week or later, and eventually succumb to the pyogenic assault of the coccus. (In staphylococcal infections in the rabbit arthritis does occur, but abscess-formation in the tissues and abnormalities of the bone-marrow are more common.) But even if serum, staphylococcal as well as streptococcal, can only combat early toxæmia, there would appear to be abundant indication for its employment clinically. The evidence adduced by Panton, Valentine, and Dix (1931) lends support to this contention.

Much further work is obviously necessary to establish the value of both staphylococcal toxoid and antitoxin in clinical medicine. It is suggested that frequent titrations of the antihæmolysin present in the patient's serum, by a method similar to that described earlier in this paper, should be carried out while this research is in progress, so that valuable data may be acquired as to the precise rôle of circulating antitoxin in combating infection and influencing prognosis.

SUMMARY

1. Toxins of various strains of staphylococcus vary widely in potency. Lightly coloured variants of *aureus* strains produce more potent toxins than the parent cultures. The guinea-pig intradermic value (combining power) of toxin approximates to the hæmolytic value, when rabbit corpuscles are used.

2. A simple technique is described for titrating the antitoxin (antihæmolysin) in the serum of patients.

3. The sera of numerous laboratory animals and human subjects contain appreciable amounts of "natural" antitoxin. In human staphylococcal diseases there may be wide variations in antihæmolytic titre, the highest value being obtained in deep-seated infections—e.g., of bone and muscle.

4. Active immunisation with toxoid leads to an increase in circulating antitoxin, and affords protection against infection, at least in laboratory animals. Clinical data are accumulating, showing the value of toxoid in the treatment of subacute and chronic staphylococcal conditions in man.

5. Antitoxin protects laboratory animals passively against many lethal doses of toxin. When given to mice and rabbits before a certainly fatal dose of living culture it prolongs and in some cases saves life. It is thus a rational form of therapy in human infection, in which preliminary reports of its usefulness are not discouraging.

A CASE OF
ANAEROBIC MENINGITIS FOLLOWING MUMPS

By T. Lawson McEwan, B.Sc., M.B. St. And., D.P.H., F.I.C.
BACTERIOLOGIST TO THE DEVON COUNTY COUNCIL; AND
L. N. Jackson, *M.C.*, D.M. Oxf.

Brain abscess and purulent meningitis associated with anaerobic micro-organisms occur not infrequently as complications of such conditions as chronic otitis media and pulmonary abscess, and more rarely by metastasis from other sites. The following case presents certain unusual features.

CASE RECORD

The patient was an overgrown lad, aged 16, working as a shop assistant. Seven cases of mumps had occurred in his family, and he contracted the illness himself on April 15th, 1933. The attack was a severe one with persistent fever. Ten days from the onset he complained of headache and stiffness of the back of the neck but no changes in the reflexes could be determined. Kernig's sign was negative. The tongue was heavily coated but moist; the mouth was foul with marked halitosis. Pain in the neck became severe during the next three days, mainly along the posterior border of the left sternomastoid. The temperature was 100·8° F. No evidence of otitis media, furunculosis, or pulmonary involvement could be obtained throughout the illness. Apart from the temperature and the pain in the neck nothing abnormal was found at this time.

The temperature fell to 98° F. on April 30th, but during that night the patient had delirium, and on the following night a shivering attack. The pain in the neck and stiffness grew worse. On May 2nd the plantar reflex became extensor on the right and doubtful on the left. Of the abdominal reflexes only the right upper could be elicited. Other reflexes were normal, except for slight bilateral ankle-clonus. The temperature was 102° F. Two days later (May 4th) enlargement of the upper left posterior cervical glands was noticed. Both plantar reflexes were then flexor. The glandular enlargement was marked on the following day and now involved the left supraclavicular group. Slight bilateral ankle-clonus could still be elicited. During the next few days the patient became mentally confused and showed signs of cerebral irritation. Kernig's sign remained negative. There was slight "fluffiness" of both optic discs, but no definite papillœdema.

Lumbar puncture was done on May 7th, and about 10 c.cm. of turbid cerebro-spinal fluid were withdrawn. The fluid was under pressure. The patient was rational on the following day and the temperature had fallen to 99·5° F. Turbid cerebro-spinal fluid was again withdrawn but not under pressure. On May 9th there was slight head retraction, headache was less severe, and ankle-clonus was now absent. The pulse was markedly dicrotic. Lumbar puncture yielded blood-stained fluid under slight pressure. The upper part of the swelling of the left side of the neck in the suboccipital region was now fluctuating, and this was incised under nitrous oxide anæsthesia on May 10th. Much foul chocolate-coloured pus was evacuated, and the abscess cavity was found to extend down to the bone. That evening the temperature had fallen from 101° to 99° F., and the patient was quite rational. He felt fairly well during the next two days on both of which lumbar puncture was done, but on May 13th he became worse, with marked head retraction and nocturnal delirium. On the 14th he had slight periodic tremor of all four limbs. There was now spreading cellulitis of the neck and a considerable secondary hæmorrhage from the wound. 5 c.cm. of turbid cerebro-spinal fluid were withdrawn by lumbar puncture. The patient died on the following day. Post-mortem examination could not be obtained.

LABORATORY FINDINGS

Specimens of cerebro-spinal fluid were examined on May 7th, 8th, 9th, and 11th, the material being delivered at the laboratory within two hours of withdrawal by lumbar puncture. The fluid of May 7th and 8th was distinctly turbid. Examination showed white cells over 5000 per c.mm. (polymorphs, 89 per cent.; small lymphocytes, 8 per cent.; large mononuclears, 3 per cent.). Nonne Apelt phase II, positive; Fehling's solution, not reduced; chlorides, 680 mg. per 100 c.cm. No micro-organisms of any kind could be detected in stained films from the centrifuged deposit, and cultures, both aerobic and anaerobic, yielded no growth after 14 days' incubation at 37° C. The fluid of May 9th was heavily blood-stained, but no organisms were seen, and cultures from the centrifuged deposit and of the clot yielded no growth. The fluid obtained on May 11th (the day following incision of the abscess) showed the same cytology and chemical characters as those of May 7th and 8th, but now great numbers of streptococci and slender Gram-negative bacilli were present. Aerobic cultures failed to yield growth, but both organisms appeared in anaerobic culture.

The pus withdrawn from the suboccipital abscess on May 10th was chocolate coloured and very foul. Cells were practically all polymorphonuclears with much detritus. Large numbers of streptococci and slender Gram-negative sluggishly motile bacilli were seen, and these were cultivated anaerobically. Primary aerobic culture failed. Examination by dark-ground illumination was made of the deposit from the various specimens of cerebro-spinal fluid and of the pus from the abscess, but in no case were any organisms of spirochætal type seen. Inoculations for aerobic culture were made by heavy streak sowings upon slants of agar fortified by 1 per cent. human blood, 1 per cent. glucose, peptic digest blood agar (Fildes) and 5 per cent. rabbit serum agar. Anaerobic culture was made by serial dilution shake in 6″ × ½″ tubes containing an 8 c.cm. column of a similar range of media. Cultures were incubated at 37° C., and examined daily over a period of 14 days.

CHARACTERS OF THE MICRO-ORGANISMS

As stated, no growth was obtained in primary cultures on slants under aerobic conditions. In deep shake cultures growth appeared in from four to five days about 3 cm. from the surface. Colonies were then isolated by cutting the tubes in the usual way. The streptococci, after three or four subcultures in deep stab, came to grow readily on the surface and could then be cultivated on plates aerobically. They proved to be of *viridans* type. The bacilli, occurring as pale yellow ovoid colonies of hazy outline, were slender rods, varying in length from 4 to 12 µ, and were pointed at both ends. They exhibited no pleomorphism and were Gram-negative and non-acid-fast. Sluggish motility was observed in individuals from young colonies. Repeated examination by dark-ground illumination failed to show any spiral forms in these cultures. Similar organisms were obtained from the cerebro-spinal fluid and from the abscess pus. Growth of the bacilli in subculture was poor and failed entirely after the fourth subculture. It was not possible to carry out pathogenicity experiments on animals.

DISCUSSION

Several cases of meningitis or brain abscess associated with a mixed infection by anaerobic fusiform bacilli and cocci are noted in the literature. Von Hibler[1] describes a brain abscess in which Gram-positive cocci and anaerobic bacilli were found; Russ[2] describes an influenza-like bacillus associated with a streptococcus. Dick[3] at post-mortem examination found: (*a*) slender Gram-negative bacilli and *Streptococcus viridans* in purulent meningitis following otitis media; (*b*) fusiform bacilli and pneumococcus in basal meningitis following bronchiectasis; and (*c*) fusiform bacilli and *S. viridans* in the pus from cerebellar abscess and purulent lepto-meningitis. Ghon, Mucha, and Müller[4, 5] record three different types of anaerobic bacilli found in cases of meningitis: (1) a small Gram-negative bacillus tending to form chains; (2) a motile bacillus "resembling *B. typhosus*"; and (3) a slender motile bacillus associated with Gram-positive cocci. The fusiform bacillus isolated in the present case appears to resemble the third type of Ghon, Mucha, and Müller, and also that designated Type II. by Smith,[6] although it showed no tendency to develop spiral forms on culture as invariably found by Smith and Tunnicliff in Type II. The association of fusiform bacilli, spirochætes, vibrios, and cocci in various combinations is well known in such conditions as Vincent's angina, necrotic gingivitis, pulmonary abscess, and gangrene and chronic otitis. Spread may occur from these sites to a great variety of situations in the body either by direct extension or by metastasis, and brain abscess and purulent meningitis is not an unusual complication of these conditions. As regards the pathogenicity of these various anaerobic organisms, inoculation experiments in guinea-pigs and mice have shown that while any one of the members of the association has little or only very modified pathogenic properties, combinations of them can be made to reproduce conditions similar to those of the lesions from which the organisms were originally isolated. Smith,[7] working with various combinations of fusiform bacilli, spirochætes, vibrios, and cocci, found that only when spirochætes were present in the combination were the foul necrotic conditions of the original lesion reproduced. In the present case, although the pus from the abscess was characteristically foul, spiral forms could not be demonstrated by dark-ground illumination or on culture. Pathogenicity experiments were not carried out.

The train of symptoms in the present case suggests that pus-formation occurred first in or near the occipital bone. It is known that the organisms of the group occasionally invade bone either metastatically or directly, producing osteomyelitis with widespread necrosis. Seecoff [8] records a case of osteomyelitis of the frontal bone following infection of the frontal, ethmoidal, and sphenoidal sinuses by anaerobes of this group. The infection spread through the diploë and death resulted from meningitis. Silberschmidt [9] reports a metastatic abscess of the femur, and Zinserling [10] mentions direct spread from a gangrenous lung involving the destruction of several vertebræ. The external abscess in the present case was found to extend down to bone. It is significant that slight signs of intracranial involvement appeared before any swelling was detectable externally, although there was stiffness and pain at the back of the neck. The aggravation of the intracranial symptoms and the development of the external swelling proceeded more or less concurrently. It would appear that pus had formed on both aspects of the occipital bone, producing the external abscess on the one hand and an extradural abscess on the other. The earlier specimens of cerebro-spinal fluid were definitely purulent but sterile, and this is not uncommonly found with suppuration close to but not involving the meninges. Such a finding would be consistent with the presence of an extradural abscess. The final infection of the meninges indicates the rupture of this abscess internally.

The origin of the infection must remain conjectural. Autopsy was not obtained and clinical examination during the course of the illness failed to show anything definitely suggestive. It is possible that the infection originated in the mouth, which was foul throughout, but it is noteworthy that at no time was there clinical enlargement or tenderness in the anterior group of cervical glands. Fusiform bacilli and *Streptococcus viridans* have been found by Davis and Mulholland [11] and by Gilmer and Moody [12] to be the preponderant organismal association in cases of periapical abscess. In a case of anaerobic brain abscess described by Worster-Drought,[13] pyorrhœa alveolaris was the only abnormality found at post-mortem.

COPPER STRIPS FOR SPLITTING PLASTERS

AND A PLASTER OPENING TOOL

BY ERIC I. LLOYD, M.B. Camb., F.R.C.S. Eng.

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, AND ORTHOPÆDIC SURGEON TO THE ROYAL NORTHERN HOSPITAL, LONDON

PLASTER-OF-PARIS bandages are nowadays frequently applied next the skin and their removal is often a tedious process. There are numerous occasions when it is wise to split a plaster while it is still wet in order to forestall the swelling which will follow an operation or recent fracture. There must be many who have spent a wearisome hour splitting a next-the-skin plaster with a knife the day after it was applied.

There is no reason why this should not be done while the plaster is still wet provided that steps are immediately taken to maintain the close fit of the plaster until it is dry. The difficulty hitherto has been technical, because the various methods of doing it have certain disadvantages.

The time-honoured strips of lead were perhaps the best of a bad lot; while the plaster was drying, a sharp scalpel was used to cut down upon the previously inserted metal, which was then tilted slightly on its side and wriggled out of the incision. If the strips were made narrow they came out quite nicely but the knife occasionally transgressed their limits; if the strips were wider there was difficulty in getting them out of the incision without spoiling the plaster, and in both cases a sharp knife might go right through the lead unless it was so thick and heavy that it made a deep mark on the inside of the plaster.

The fingers or toes of a limb are almost always left outside the plaster-of-Paris, and consequently a strip of soft metal can be pulled straight out longitudinally after the knife has cut down upon it. This method obviates all the difficulties of the other inasmuch as we are not restricted in the width of metal used and can choose a material which is highly malleable but sufficiently resistant to a knife to be used very thin.

Soft annealed copper strips are excellent for the purpose and slide easily if they are greased with vaseline. One only is used unless a bivalved plaster is required, in which case one is laid along the front and one along the back of the limb. In the ordinary way, when plaster-of-Paris is to be applied to a limb, one of these strips is placed along its anterior aspect and secured with a few turns of plaster-of-Paris bandage or held by an assistant. The plaster is then completed and a sharp scalpel cuts down upon the copper strip throughout its length, dividing every strand until it is clear that nothing remains bridging the gap. A bandage, plaster, or a series of webbing straps then closes the gap throughout its length and the copper strip is pulled out from one end. This is done by a metal handle which is slipped across the strip and grips it with a couple of turns before the strip is pulled out. The split plaster is now allowed to dry and need only be opened if necessity arises.

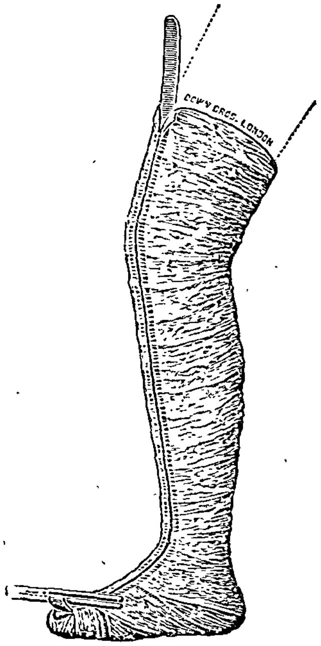

FIG. 1.—Copper strip in position. The plaster has been cut while still wet and the copper strip is about to be withdrawn.

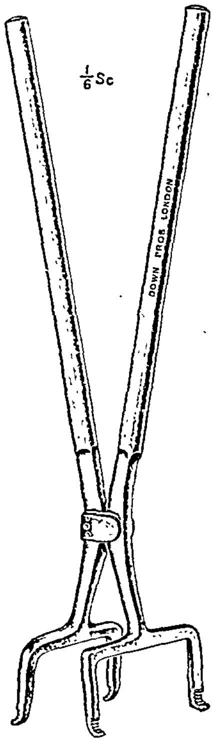

FIG. 2.—Plaster openers.

If plaster is applied over dressings, flannel bandage, or wool, the same technique is followed except that the copper strip is then placed next this instead of next the skin.

It might be thought that a plaster would be greatly weakened by a split throughout its length, but I have not found it so and I now often use these copper strips when applying plaster-of-Paris.

Removal of the plaster is greatly facilitated by the split in the plaster and is usually the work of a few seconds if the proper plaster opener is at hand.

This is a large double-pronged lever which takes apart rather like a pair of midwifery forceps and is inserted, one pair of levers at a time, into the chink in the plaster. The two parts of the plaster opener are then locked into position and the plaster levered open. It depends on the length of the plaster whether the opener has to be inserted in more than one place, but in any event it is a simple matter to repeat the process or to use a second plaster opener higher up the limb. It will be noticed from the shape of the lower ends and their radius of action that there is no risk of the levers injuring the limb if they have once been properly inserted.

The copper strips are made in sets of four (two of 18 in. long and one each of 26 and 32 in.). They are all of the same thickness, but the width is 1 in. for the short length and $1\frac{3}{8}$ in. for the longer. Two handles are supplied with each set and they may also be used for rolling out kinks after use, though this is easily done round any circular surface such as a chair leg. If these kinks are not eliminated, the knife may miss an occasional strand of bandage and the division of the plaster be incomplete.

The plaster openers were based on a pattern which has been known in this country for some years but they now bear little resemblance to their origin. The virtue of the copper strips lies in their thinness, malleability, and resistance to a knife. Whether original or not, I venture to think the two make a useful addition to the equipment of any surgeon who works with plaster-of-Paris. Both have been made for me by Messrs. Down Bros., 21, St. Thomas's-street, S.E.1.

Clinical and Laboratory Notes

A SECOND ATTACK OF PNEUMOCOCCAL MENINGITIS

By J. Gordon Clark, M.D. St. And.
CLINICAL ASSISTANT, DUNDEE ROYAL INFIRMARY; CLINICAL TUTOR, UNIVERSITY OF ST. ANDREWS

In December, 1932, I reported a case of pneumococcal meningitis in which the patient recovered (The Lancet, 1932, ii., 1330). I have now to record a second attack of pneumococcal meningitis in the same patient, resulting in death. From a review of the literature it appears that recovery from pneumococcal meningitis is uncommon, only about 50 authentic cases having been described (the first by Jemma in 1896). In none of these cases is there a record of a second attack of pneumococcal meningitis, and in this respect the present case seems to be unique.

First attack.—The patient was aged 29 when the first attack of pneumococcal meningitis occurred on April 16th, 1932. The onset was abrupt, characterised by severe frontal headache. Within five hours he was unconscious, and when admitted to Prof. A. Patrick's ward in Dundee Royal Infirmary seven hours after the onset he was unconscious and violent. With intervals during which he was rational his condition remained the same for 18 days. Then he gradually improved, and when he was discharged from hospital on June 28th he appeared to have recovered. Papillœdema, which had been severe, had subsided, and no visual defect remained. He was examined at monthly intervals thereafter and showed no sign of the disease. On Dec. 7th, 1932, lumbar puncture revealed a normal cerebro-spinal fluid. After that date he did not report again. The diagnosis had been confirmed by culture of pneumococci from the cerebro-spinal fluid.

Second attack.—The patient had been in good health since December, 1932, and had resumed his occupation as a shepherd. Occasionally he had complained of slight frontal headache.

On March 5th, 1934, he had been working during the morning. At midday he complained of severe headache of sudden onset. About 7 P.M. he became unconscious, and on admission to Dundee Royal Infirmary on the following morning he was unconscious and violent. His appearance resembled that observed at the commencement of the first attack of meningitis two years before. The cerebro-spinal fluid was turbid, under normal tension, and contained 11,300 cells per c.mm., all polymorphonuclears. Pneumococci were present in the film, and were grown in pure culture. The organism was found by Prof. W. J. Tulloch to belong to type IV. During the first attack of meningitis, lumbar puncture, performed daily, had appeared to afford relief, and it was proposed to carry out the same treatment during the present illness. His condition failed to improve, however, and he died three days after the onset of the disease on March 8th.

Post-mortem findings.—At autopsy, by Prof. D. F. Cappell, the brain was found to be soft and hyperæmic. Green purulent exudate had collected at the base of the brain and round the brain stem. A thin film of exudate covered the cortex of the cerebral hemispheres. The middle ear on both sides and the cranial sinuses were healthy. There was no evidence of lung consolidation, and there was no respiratory catarrh. No primary focus could be demonstrated which might have been responsible for infection of the meninges.

The clinical picture during the corresponding period in both attacks was similar. The abrupt onset with headache, followed within a few hours by mental excitement, restlessness, and unconsciousness, occurred in both attacks. In the first attack the cerebro-spinal fluid was less turbid, and contained fewer pus cells (1650 per c.mm., as against 11,300 in the second attack). In both no primary focus of infection could be found clinically, and in the second autopsy failed to reveal it.

I am indebted to Prof. Patrick for permission to publish the case.

CHEMICAL SPOT TEST IN DIAGNOSIS OF URÆMIA

By Jocelyn Patterson, M.Sc., Ph.D.
BIOCHEMIST, CHARING CROSS HOSPITAL

(*From the Institute of Pathology, Charing Cross Hospital*)

A TEST diagnostic of high blood-urea was devised by Weltmann and Barrenscheen,[1] who utilised the reaction between urea and p-dimethylaminobenzaldehyde (Ehrlich's reagent), which gives rise to a yellowish-green coloration of somewhat low intensity. Preparatory to applying the reagent to blood they precipitated the proteins with trichloracetic acid, and after filtering developed the colour in a clear filtrate. Blood specimens containing a normal amount of urea (20–40 mg. per 100 c.cm.) developed no perceptible colour, whereas those much above normal in respect to urea content showed the characteristic coloration, which was the more intense the higher the amount of urea present.

The reaction thus outlined, though attention was called to it by Hunt,[2] does not seem to have been employed to any large extent in this country, probably because the time and labour involved is only slightly less than some of the direct Nesslerisation or hypobromite methods, which go further in achieving a roughly quantitative estimation of blood-urea.

For several years past in this laboratory a simpler modification of the reaction has been in use and has proved invaluable in routine work. This consists merely in applying a drop of Ehrlich's reagent directly to a drop of plasma placed on a white filter paper. Where there is much nitrogen retention the spot on the filter paper shows immediately the characteristic greenish colour, no appreciable colour being present with normal or slightly raised blood-urea. More recently attention has been given to the best means of applying the spot reaction directly to whole blood, so as to provide a test which might well be done at the bedside. The technique described below, employing a composite reagent, has been found to work very satisfactorily and takes only one minute to perform on a given sample of blood.

Reagent.—To the Erhlich's reagent (10 g. p-dimethylaminobenzaldehyde, 100 c.cm. concentrated HCl, made up to a total volume of 300 c.cm. with distilled water), add 20 per cent. trichloracetic acid drop by drop with shaking until the cloudiness which forms with each drop just faintly persists.

Technique.—To a small volume of blood placed in a narrow test-tube—a few drops of oxalated finger blood will suffice—add an approximately equal volume of the reagent. Shake the mixture vigorously for a few seconds, and then pour a drop of the somewhat thick coagulum on to a white filter paper. The filtrate spreads as a gradually extending circle, leaving a brown centre of precipitated protein. Attention is then directed to that part of the spot external to the dark centre. With true uræmia the spot shows a distinct green colour. Blood specimens with normal or only slightly raised urea content show no coloration against the white background.

The subsequent development of the outer area of the spot has a certain amount of interest in a confirmatory sense. When dry the degree of yellow of a uræmia spot very slowly intensifies, and after the lapse of several hours the spot becomes a bright canary yellow. Bloods displaying little or no urea retention eventually leave only a dull pale green spot.

The test is of course no substitute for the blood-urea estimation; indeed it ought in general to be followed up by an exact determination. It is, however, eminently suitable for conditions of emergency where it is desired to ascertain at once whether or not there is gross retention of nitrogen.

SHROPSHIRE ORTHOPÆDIC HOSPITAL.—The long task of reconstructing this institution was reported at the recent annual meeting to be making fair progress. The trustees of the James Laing Trust have given £10,000 for memorials, to form part of the building, of the late James and Nancy Laing. Last year 1328 patients were treated—787 adults and 541 children. The adults stayed on an average 118, and the children 105 days. There was a credit balance on the year of £301.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS AND GYNÆCOLOGY

AT a meeting of this section on May 11th, with Dr. J. S. FAIRBAIRN in the chair, the subject of discussion was

Genital Prolapse

Mr. VICTOR BONNEY, in opening, said that the distressing charge had often been levelled against gynæcologists that no two of them held the same views about anything, and in respect to the cause of genital prolapse in women there seemed some justification for the criticism. He quoted varying views from a dozen current text-books on the matter, and submitted that the time had now arrived for a general consensus of opinion on the mechanism of prolapse. He contended that, contrary to the view underlying the expression "falling of the womb," prolapse was a purely vaginal phenomenon, one in which the uterus did not play a part; indeed the latter might constitute a hindrance to the prolapse. The vagina, in its relation to the peritoneal cavity, was best considered as a cul-de-sac which was intruded into a closed cavity the pressure within which was liable to sudden rises. The intra-abdominal pressure depended partly on the gas pressure in the intestines, partly on the muscular contraction of the parietes, and partly on the weight of the movable viscera. A perfectly free thin-walled cul-de-sac so situated would turn inside out when pressure in the closed cavity was raised sufficiently. So also would the vagina when the intraperitoneal pressure rose were it not for the ingenious mechanism evolved by nature to prevent it. Mr. Bonney regarded the cardinal ligaments as being more important in the occurrence of prolapse than the so-called pelvic floor. A mere bulging of the parietes would drag on the vagina but would not turn it inside out. He preferred the term "cardinal ligaments" to "utero-sacral ligaments." The worst cases of prolapse seen were those in women past the menopause. Prolapse manifested itself in forms which varied according to which structures were defective in the supporting architecture of the vagina, and Mr. Bonney described in detail and showed illustrations of the various operations which had been devised to deal with them. No operation, he said, was ideal which did not take into account and rectify or abrogate all the factors which were responsible for the particular deformity; hence no procedure could be regarded as a panacea for all cases.

Prof. FLETCHER SHAW directed his remarks especially to treatment. It was said that in Manchester all cases of prolapse were treated by one operation, but each case was, in fact, dealt with as its particular features required. In one case there might be more cystocele, in another more rectocele. The most important parts were those above the muscle and those attached to the muscle itself. The general principle in treatment, however, was to tighten up the parametrium and the muscle lower down to the levatores ani. It was not removal of vaginal tissue which was important, but the stitching of the deep tissues. In practically all the cases the uterus was left in an anteverted position and therefore maintained in anteversion. In the operation he did not rely on the reduction in size of the vagina by removal of vaginal mucosa, though a certain amount was removed. A factor common to every case of prolapse was some weakening of the muscular floor of the pelvis, due either to congenital or development causes, or, more commonly, to damage during labour. In most cases, however, there was an additional cause, sometimes increased abdominal pressure as in factory workers. This probably accounted for many cases seen in the north of England in virgins. The weight of a fibroid of the uterus or subinvolution of the uterus might be a factor. Prof. Fletcher Shaw said that his figures took account only of results that had persisted for at least three years. In 529 cases of operation for prolapse there were no deaths and at his hospital the unsatisfactory cases numbered only 20 (or 3·64 per cent.), and these 20 included those who experienced any symptoms at all since the operation; 5 had had subsequent confinements and 4 failed to come for further examination. In those confined again it was reasonable to suppose that the subsequent labour caused recurrence of the prolapse. Eight had some laxity of the posterior fornix very difficult to cure. During 25 years Prof. Fletcher Shaw had had 9 deaths following this operation, the causes including pneumonia, heart failure, embolism, cystitis, pyelitis. Only 27 of the women in his series had had children after the operation; the tendency was to defer the operation until they had had what they regarded as a reasonable family; 22 of them were all right, while 5 had had a recurrence. In his experience there was practically never any difficulty with subsequent labour which was mostly easier and shorter, because part of the cervix had been removed. In patients operated upon over 50 years of age there were 97 per cent. of cures; in the 4 cases not cured the disability was very slight. A number of the cured cases ranged in age from 70 to 75. In nulliparæ the cures from the operation were 96·9 per cent. The belief of himself and his colleagues was that the pelvic organs were held in place by the muscular tissue and the parametrium, and that prolapse meant that these tissues were weakened by some such cause as he had referred to. It was also their belief that all these cases could be cured by the operation which had been devised for buttressing, shortening, and firming up the tissue concerned. The results of the operation had been, in the experience of Manchester, excellent.

Prof. A. LEYLAND ROBINSON based his remarks on the assumption that descent was due to weakness of the supports of the genital apparatus, or to an increase of strain upon them. Congenital defect was fairly common; it was shown in the rapid onset of symptoms in young primiparæ after normal labour. With regard to acquired predisposition, the efficiency of the structures supporting the birth canal could be impaired in two ways: by lacerations, causing severe mechanical defects, or by muscular weakness or atrophy induced by subinvolution, the menopause, or severe debility. Any injury was, naturally, at once attended to, but loss of muscle tone might supervene after a normal delivery, or might be associated with hidden injuries, such as internal rupture of the levatores muscles. In the absence of actual injury this lowering of muscle tone was apt to be overlooked until the onset of symptoms drew attention to prolapse. In a woman with inherent muscle weakness any such factor as increased abdominal pressure, constipation, over-work, bronchitis, could initiate descent.

As to prevention, any procedure which protected the pelvic muscles from undue pressure, over-stretching, or laceration would deter descent of uterus and vagina. The condition of the pelvic floor should have an influence in deciding as to the mode of delivery in any given case. He emphasised the importance of episiotomy for the prevention of prolapse. Pessaries were useful (1) for diagnosis, (2) as a temporary measure for healthy parous women, and (3) as a palliative. Operation the speaker regarded as curative only after the cessation of the childbearing period of life, but surgery might be needed for the repair of injuries or to relieve symptoms. He recognised two clinical groups of cases, according to whether the defect was in the middle and upper or lower supports of the birth canal. He was a firm believer in the efficiency of vaginal operations for the cure of prolapse. His experience with over a thousand cases had convinced him of the soundness of the so-called "Manchester operation," which he analysed to show its advantages. By its means the length of the vagina was increased rather than diminished, the external contours reappeared, and the normal functions of the vulva as a shock-absorber and a barrier to infection were restored to the patient.

The **PRESIDENT** said he considered that the method described by Prof. Robinson of tightening the utero-sacral ligaments was valuable as it avoided the tendency mentioned by Prof. Fletcher Shaw as a common cause of failure for the posterior fornix to come down.

Prof. V. B. **GREEN-ARMYTAGE** held that in this country gynæcologists were prone to be too conservative in these matters, and to adhere to one particular kind of operation. He thought that close adherence to the operation of the Manchester school had blinded gynæcologists to the defects and disadvantages of that procedure. In America and several continental countries prolapse cases were divided into three categories: (1) the woman with prolapse who wanted more children—for her, a modified Manchester operation without amputation of the cervix gave this possibility and made a cure; (2) the woman with prolapse who did not want more children—here the interposition operation gave excellent results; (3) the woman over 45, for whom the valuable Mayo-Ward operation could be performed; it took only 30 minutes. Prolapse in virgins under 20 years of age was one of the chief bugbears of the specialty, and he would have liked to hear particulars of the method by which Prof. Fletcher Shaw dealt with these cases.

Mr. J. M. **WYATT** said he did not remember to have seen a case of prolapse in a virgin under 40 years of age unless there was a fractured pelvis. As to the strain of work, he believed that young women worked as hard in London as elsewhere, yet they did not seem to suffer from prolapse due to this cause. He believed prolapse was often due to severe strain short of laceration. Sometimes after prolonged labour prolapse took place, but without any perineal tear, whereas a quicker delivery, even if accompanied by a tear, did not result in prolapse. He had seen many cases in which the prolapse was limited to the lower vagina; they were cases of low rectocele or low cystocele, and he did not think the Fothergill operation was of value in dealing with such cases.

Mr. J. **CHASSAR MOIR** remarked that Prof. Fletcher Shaw had described what he termed the important deep stitching to brace the uterus, and then, he said, he amputated the cervix. Dr. Moir would like to know why this last was done. It meant primary bleeding, and probably secondary bleeding at the end of a week. He had sometimes known considerable hæmorrhage occur after the Manchester operation, and would like to know how this could best be avoided.

Mr. **BONNEY**, in reply, said the debate had shown that the three openers were substantially in agreement, but the text-books on the subject did not reveal such harmony, or what prolapse essentially consisted of. He still did not think that the uterus had anything to do with prolapse: in fact the larger the uterus the more definite the resistance it offered to the occurrence of prolapse. Mr. Bonney did not regard the interposition operation as a good procedure. It was not an anatomical operation and was not comparable with the Fothergill, or the other operations usually performed at that site. It seemed to act partly by pulling on the cardinal ligaments, partly by reinforcing the anterior vaginal wall. Not only for the sake of patients and operators, but also that of students, he hoped agreement on the nature of genital prolapse would be attained.

Prof. **FLETCHER SHAW** replied that all three openers were agreed that in every case of prolapse there was a deficiency in the supporting structures, as a result of either congenital weakness or of some damage. He still thought that the weight of the uterus had some effect in bringing about prolapse, but only in the presence of such weakness as he mentioned. He thought the figures he was able to produce were sufficient justification for loyalty to the Manchester operation. He did not think the interposition operation was ever required for prolapse. In almost every case he removed the cervix but there were a few exceptions. Even if the cervix appeared to be normal, the use of sutures pushed it further down the vagina. Hæmorrhage might occur at the end of seven days, and that he regarded as evidence of sepsis. If the first indication was overlooked there might be trouble. Practically always when bleeding occurred it was from the cervix. If the urine was turbid, cystitis should always be suspected, the urine examined microscopically, and, if infected, treated before any operation was performed.

MEDICAL SOCIETY OF LONDON

As the subject for the annual oration delivered on May 14th Prof. G. E. **GASK** chose

Clean Wounds, Ancient and Modern

remarking that it might come as a surprise to some of his hearers to learn that modern aseptic surgery, of which we are so proud, is not entirely the product of our generation. There were at least two previous periods in past ages in which clean and rational surgery was practised. On a roll of papyrus 5000 years old which came into the possession of an American Egyptologist, Mr. Edwin Smith, during the American Civil War, was given by his daughter to the New York Historical Society in 1906, was translated by James Henry Breasted and published in 1930, is a description of 48 cases, written in a style which suggests that it was for the instruction of students. Details are given of a number of flesh wounds: the treatment being similar in all cases, it may be inferred that it was the accepted practice of the time. In the first place the wound was to be closed by stitching, and from the fact that the stitching is mentioned early and is included in the diagnosis, we may conclude that the wound was to be closed at the earliest possible moment. In the second place fresh meat was to be bound upon the wound for the first day, and for the first day only. In the third place the stitching was to be loose, the edges of the wound being drawn together by two strips, presumably of plaster. Finally the wound was to be dressed with grease and honey every day until healed. Fresh bleeding meat is a useful styptic and may assist bactericidal action. Honey is the same as the treatment with hypertonic solution introduced by Sir Almroth Wright.

The Hippocratic method of treating wounds, said Prof. Gask, compared favourably with that of modern times. Water for washing wounds was filtered or boiled. Dressings were of new material, and the hands and nails of the operator were cleaned. Their local medications were wine and oil. As Greece declined, the Grecian school shifted to Alexandria and later to Italy. Galen, who worked in Rome about A.D. 150, was described as the founder of experimental medicine. He taught the world much, but he tried to explain everything in the light of pure theory instead of by careful observation and interpretation of facts. Some of his doctrines, accepted as gospel truth, had much to do with preventing the advancement of medical science. One of the most notable of these superstitions was the Galenic doctrine that "coction," or suppuration as we would now call it, was an essential part of the healing of wounds. This damnable doctrine was handed down from generation to generation until it was disproved by Lister.

Hugh of Lucca, known only through the works of his son, Theodoric (Teodorico Borgognoni), who completed his book on surgery in 1266, recognised that suppuration is not a necessary stage in the healing of a wound. "It is not necessary," he wrote, "to place a poultice over a suture, as the stupid do, . . . to generate pus in wounds, as almost all modern surgeons profess. No error can be greater than this. It is nothing else but to hinder nature, to prolong the disease . . . and what is worse the unskilful bring it about with their cures that flat wounds suppurate and hollow ones become fistulous." Theodoric's pupil, Henri de Mondeville, has left a vivid picture of the contemporary method of treating wounds, which he called the treatment of the ancients, adding "By this treatment more patients die than recover and the convalescence of those that survive the treatment is prolonged for three months." He himself elaborated a form of treatment of wounds and gave practical proof of the value of his treatment which must have convinced all but those who did not wish to see. These were his instructions :—

> Do not probe wounds.
> Remove all foreign bodies.
> Approximate the lips of the wound as much as possible and suture them if necessary.
> Foment afterwards with warm wine.
> Dry them with pledgets soaked in wine.
> Apply a plaster spread on a piece of tissue and cover it again with pledgets wrung out in wine.
> Bandage according to the rules of the art.

He believed and proved by experiment that suppuration was not an essential phase of healing, and that wounds properly treated "heal in a little time, without pain, and with a single dressing." But after his death his treatment fell into disuse.

Passing on to the middle of the nineteenth century, Prof. Gask invited his hearers to the small chemical laboratory attached to a brewery in Lille, where Pasteur's discovery that fermentation and putrefaction were due to the action of living organisms made possible the progress of modern surgery and preventive medicine. Lister seized on Pasteur's discovery and with it made surgery safe for humanity. He had long wondered why Lister chose such an inconvenient antiseptic as carbolic acid when he had heat ready to his hand. Lister must have had good reasons for his choice. What were they ? It was in 1860 that Lister went to Glasgow Infirmary and was distressed at the frightful mortality there of suppurating wounds and the ravages of hospital gangrene. Dr. Thomas Anderson, who had studied under Berzelius and Liebig, was then regius professor of chemistry in the university. Lister and Anderson lived near each other in the West of Glasgow, and it was Anderson who called Lister's attention to Pasteur's discovery of the dependence of putrefaction on minute living organisms. Prof. Gask imagined Lister saying "If these tiny organisms are the cause of putrefaction, it is possible they are the cause of suppuration, and if one could prevent them from entering the wound one might prevent suppuration. It is worth trying." Then it would seem natural for him to turn to Anderson and ask : "How can I kill these organisms ?" As a chemist Anderson was likely to think along chemical lines. A large sewage farm, recently made to the west of Carlisle, had given annoyance by its smells and carbolic acid had been found to be the most efficient preventive. Perhaps Lister made a journey to Carlisle to see for himself what was done ; at all events, he secured some crude carbolic acid and began his investigations.

Had Pasteur been a surgeon he might have chosen heat as his sterilising agent. In fact, when addressing surgeons at the Académie de Médecine in 1874, he said :—

> "Surgical instruments should . . . be put through a flame . . . for this reason : if a sound were examined with a microscope, it would be seen that the surface presents grooves where dusts are harboured, which cannot be completely removed even by the most careful cleansing. Fire entirely destroys these organic dusts ; in my laboratory . . . I never make use of an instrument without previously passing it through a flame."

It is easy enough for us to realise now, Prof. Gask remarked, that heat is the best method of sterilisation, but the fact remains that Lister chose a chemical disinfectant, in the first instance probably because he was told of it by his friend Dr. Anderson, and secondly perhaps because he was looking for a substance which would kill germs which were in the air, as well as those which had already settled in and contaminated the wound. In his later years Lister was filled by the idea that his work had been ineffective. He could not see the need for the modern operating theatre, with its ritual of cleanliness, and he thought the lessons he had taught were wasted. But although much has been done, still more remains to do. Though a surgeon may make a clean wound and carry out intricate operations with the certainty that healing will be swift, he is still almost powerless in the face of an infected wound. Can we say, Prof. Gask asked, that we have materially improved the treatment of pyogenic infections ? Can we cure even a whitlow, or a poisoned wound, with the assurance with which we can make a clean cut ?

WEST END HOSPITAL FOR NERVOUS DISEASES.—Last year there were 585 in-patients and 4000 out-patients, and income exceeded expenditure by £2596. The work of the pathological, neuro-surgical, and psychotherapeutic departments increased substantially during the year, and the staff of the child guidance unit has been nearly doubled to deal with the demands made upon it in its first year of working. The X ray apparatus has been condemned and re-equipment will cost £1000. At the annual meeting last week Lord Harewood, the chairman, announced that the pathological department is to be named after the late Mrs. (Josephine) Marshall, of New York, "in connexion with a generous gift which is to be received from Mr. Charles Marshall and Mrs. Field."

REVIEWS AND NOTICES OF BOOKS

Rheumatism in General Practice

BY MATTHEW B. RAY, D.S.O., M.D. Edin., Senior Physician, the British Red Cross Clinic for Rheumatism; Physician, the St. Marylebone General Dispensary. London: H. K. Lewis and Co., Ltd. 1934. Pp. 404. 16s.

THE development of interest in the rheumatic diseases has resulted in a glut of text-books on different aspects of the subject, though there are relatively few, anyway in the English language, which set out to cover the whole ground. Dr. Ray has succeeded in doing this in a book of quite moderate dimensions. The book is divided into two parts: the first gives a general consideration of the ætiology, clinical features, diagnosis, and treatment of these affections; the second deals with their local manifestations in the various regions of the body. The text is illustrated by six plates, five of which are X ray photographs of the hand in different forms of or different stages of arthritis with a normal hand for comparison. The preliminary chapter covers such considerations as the physiology of the skin, heat regulation, the adaptive functions of the body, the endocrine system, and so on. The next seven chapters are devoted to a detailed description of the various forms of rheumatism and arthritis. Some would criticise the space devoted to rheumatism in children, particularly the section on rheumatic heart disease. It is doubtful whether it is possible to treat usefully so big and important a subject in one chapter. The section on fibrositic affections is admirable, and the anatomical notes are most helpful. There seems no good reason for the distinction, in Chapter VII., between gout and metabolic arthritis, since Dr. Ray states—and it is the common view—that gout is a disorder of metabolism and probably an allergic condition. The two chapters on physical treatment which end the first section will be invaluable to those who are unfamiliar with the methods of physiotherapy.

In the second part of the book each region of the body is considered in turn, with the forms of arthritis that may attack it. From the point of view of diagnosis this section should be most helpful. One omission is worthy of mention. We searched in vain for an account of the so-called climacteric arthritis which has attracted much attention of late years.

This book will interest and inform all those who are interested in the rheumatic diseases. It would be even more useful to the general practitioner for whom it is designed if some expression of personal opinion, some advice on the best lines to pursue, were offered him. The conflicting views are fully and faithfully set out and the choice between them left to the reader. In this sense the book fails to give help where it is needed; in other respects it justifies Lord Horder's warm praise in the "foreword," that it is "the best account of rheumatism in our language."

The Way of all Women

BY M. ESTHER HARDING, M.D., M.R.C.P. With an introduction by C. G. JUNG. London: Longmans, Green and Co. 1933. Pp. 315. 15s.

THIS books aims at interpreting the main problems of woman's life in terms of the psychological system of Dr. C. G. Jung, and it shares the disconcerting qualities of Jung's writings. An elusive intimation is conveyed, throughout, of new and valuable ideas; but the impression is blurred and our anticipations disappointed by the author's limited power of exposition. Just as the reader feels that he is about to get to the core of the argument, his comprehension is frustrated by a lapse into symbolic language, or else by the attribution of a strained ulterior meaning to such words as Truth, Reality, and Life.

Woman, according to Dr. Harding, has to pass through a naïve, a sophisticated, and a "redeemed" phase. When the uncritical victim of the instinctive forces of nature, or of the conventions of the society in which she lives, woman is in the naïve stage. The sophisticated stage characterises the woman of the world, who, intent on power or superiority, exploits men for money or for prestige, or for the satisfaction of her instincts. The flirt, the gold-digger, the scalp-hunter, and the courtesan are instances. Both naïve and sophisticated women belong to a "lower" type. What, the reader expectantly asks, distinguishes the higher or redeemed type? Several answers are given, varying in comprehensibility. Thus the redeemed type of woman is said to be characterised by having discovered a "supra-personal value," such as the ideal of liberty or fraternity, or the love of God, or the study of analytical psychology; by a new orientation of consciousness which centres itself in a non-personal region of the psyche (this non-personal quality should prevent her from using the term "I" to express the new conception of self); by allowing her libido to activate her primordial images and by taking her fantasies seriously; by allegiance to the aims of a part of her self which is in harmony with the movement of Life throughout the generations; by a "deeper" experience of feminine spirituality or Eros; also by the *Reality* of her inner experience and by her contact with inner *Truth.*

In her passage through the above-mentioned stages the woman must learn to distinguish her "individuality" (the differentiation of this entity is the keynote of the whole book) from the "anima" projected upon her by men, and from the "animus" which she herself projects on to men. The "anima" is the ideal of the perfect woman, secretly cherished by all unredeemed men; the animus serves the same function, vice versa, for the woman. We are informed, however, that at times, by a supreme effort, the animus, felt by the woman as a ghostly lover, may be changed into the "redeemed" or "spiritual" animus. These qualifying adjectives do not give us much information about the new kind of animus. How then is a woman to recognise her "redeemed animus"? By the fact, we are told, that through it she gains a relation to the masculine principle in herself, the Logos or Wisdom. "When," says Dr. Harding, "the woman is identified to the animus, she is possessed by influences and rationalisations and so-called principles which do not represent true wisdom at all. These are the work of the ghostly lover. *True* wisdom can be known only through the spiritual or redeemed animus who is a mediator between the conscious and unconscious."

Though the author's failure to clarify the philosophical assumptions of the Jungian system may be regretted, her book contains much that can be warmly praised. The chapters on Work, Friendship, Marriage, and Maternity contain many valuable ideas and useful phrases, and this is also true of those entitled "Off the Beaten Track" and "Autumn and Winter." The book is not written especially for medical readers, but it will be found useful by many of these in affording a picture of normal psychological development which may help them to guide a certain type of neurotic and unstable female patient towards mental stability.

The Singing Voice

By E. R. GARNETT PASSE, M.R.C.S., L.R.C.P., D.L.O., B.D.Sc. With a foreword by CLIVE CAREY. London: Sir Isaac Pitman and Sons. 1933. Pp. 85. 6*s.*

Mr. Clive Carey, in a foreword to this little book, says that it has always been a debatable question as to how far a singer should possess a knowledge of the physiology of the throat, the usual contention being that such knowledge makes him "throat conscious" and is to be discouraged. In his opinion the problem is rather whether the student should learn his art by imitation and sensation alone, or whether he should obtain mastery through conscious knowledge of what he is doing; and he makes the curious remark that some knowledge of the functions of the jaw, palate, tongue, lips, and resonance chambers is necessary to enable him to experience any sensations at all. Dr. Passe begins with an elementary account of the physics of sound and of audition, proceeds to describe the anatomy and physiology of the vocal organs and their action in the production of sound, and concludes with a short chapter on their care; the most valuable part of this latter section is the warning against using the voice when the throat is inflamed. He makes a number of loose statements; some of these are amusing and unimportant, as when he says that small fishes are able to appreciate the vibrations set up in the water by the fins of other fishes of their size and species, whilst these are imperceptible to larger fishes. Others are more serious, such as the statement that the vocal cords actually touch each other all the way along their edges during phonation, and that the nasal cavity is completely shut off by the palate during the singing of vowel-sounds. His description of the mechanism of the formation of vowels and consonants is too incomplete to be of much assistance to the student of singing; indeed, Dr. Passe has been so careful throughout to avoid instruction in the details of voice-production that he has failed to inform the student on many matters which concern him. At any rate he has avoided any risk of making pupils "throat conscious" by too much knowledge.

Practitioner's Library of Medicine and Surgery

Vol. V., *Traumatic Surgery.* Associate Editor: THEODORE S. MOÏSE, B.A., M.D., Surgeon to the Eastern Maine General Hospital, Bangor, U.S.A. London and New York: D. Appleton-Century Company. 1934. Pp. 1080. 50*s.*

THIS volume is but one in a comprehensive series covering the whole subject of surgery, general and orthopædic. Since the aim of the series is to cater for the general practitioner, one is forced both by the scope of the work and by its bulk to consider it as a work of reference. No one outside the sphere of specialised surgery is likely to read the work as a whole. The authors of the various sections of the volume on traumatic surgery have observed to quite different degrees the idea of ready and easily accessible reference. Faced with an accident to treat, the practitioner wants to know primarily what are the symptoms pointing to serious trauma, and how far he is likely to be able to treat the case himself; secondarily, he wants to know how much can be expected for his patient from major surgical interference.

The just balance between these two aspects of the subject is nicely held in the section on traumatic surgery of the genito-urinary tract, which is, incidentally, one of the best in the book. The outlook of the practitioner is rather lost sight of in descriptions of such subjects as operations for rupture of the lesser curvature of the stomach, exploration of the bile-passages, or diagnostic blocking of the sympathetic nerve-supply to the extremities. More practical is the excellent section on pyogenic infections of the hand, with illustrations of actual cases, before and after treatment, and indications of the exact incision employed. The survey of the various types of treatment of burns is full and critical, showing finally the rationale on which the tannic acid method is based. Treatment of septic wounds by the Carrel-Dakin technique is described in detail. Compound fractures are, however, dismissed in four pages, without definite stress having been laid on the necessity of regarding these injuries as among the primary surgical emergencies. The treatment by the closed method of Winnett Orr is not mentioned. Fractures and dislocations occupy nearly 400 pages of the text, and these are not among the best sections. The accounts of fractures in particular are difficult to follow. To say that the tibia is noted for its "inability to unite following fracture" does not seem to get us much further. An illustration of a fracture of the *ulna* (p. 220) is given to show the action of the pronator quadratus in producing displacement of the fractured *radius.* It seems probable that Figs. 154, 176, and 185 are all in their wrong context. There is a curious naïvety about such a remark in a text-book as " . . . one had better call in specialised aid in order to avoid difficulties later. If complications then occur one's mind is at ease with the feeling that all care has been exercised."

In spite of the unevenness of the different sections, there is sufficient material in the volume to repay study, but its value as a work of reference is to those who already have a critical appreciation of surgical problems.

Smoke and the Atmosphere

By J. R. ASHWORTH, D.Sc. Manchester University Press. 1933. Pp. 131. 7*s.* 6*d.*

THIS is a description of experiments made by Dr. Ashworth upon atmospheric pollution in Rochdale. He describes a variety of methods which he has evolved for examining the purity of the air, and his book is certainly a record of great enthusiasm and energy in examining a subject which receives far too little attention.

Many of his experiments were made with wet deposit gauges which, as he points out, give a heavier deposit than dry gauges. The effect of size, position, and exposure of gauges is discussed and also that of wind upon the deposit obtained. The wind is credited with blowing impurities out of the dry gauge, but of failing to do so when rainwater is allowed to collect in the bottom. Dr. Ashworth favours the latter type of gauge, although the dry gauge has been standardised by the Committee for the Investigation of Atmospheric Pollution. This preference for the wet gauge gives rise to some slight discrepancies in the argument. For example, on p. 24, the deposits in Cheltenham and Wakefield are compared and inferences are drawn which are hardly justified in view of the fact that the Cheltenham gauge was a wet one, the Wakefield gauge a standard one. Descriptions are given of the author's "horizontal gauge," which is intended to catch impurities carried horizontally; also of the "daily deposit recorder," which aims at getting the amount of deposit from hour to hour during the day; how far the results obtained by these instruments can be accepted as reliable is a matter of some doubt. It is not easy to measure a deposit as Dr. Ashworth does by simply counting, with the naked eye, the number of particles falling upon a piece of greased paper; the limitations of vision alone would cause the omission from the observed deposit of all particles except the very large ones. Such inferences as that "one million particles weigh almost exactly 1 gramme," can hardly be justified. An interesting theory is advanced to the effect that the rainfall is influenced by the quantity of atmospheric impurity; it was found that Sundays in Rochdale give a lower rainfall than weekdays. A chapter is included on the effect of pollution on light, and the author's photographic method of measuring ultra-violet light is described. There are five appendices and a list of references. The book makes interesting reading for anyone concerned with the problem of atmospheric pollution.

Prof. G. B. HASSIN informs us, in reference to the review of his book on "Histopathology of the Peripheral and Central Nervous Systems," in THE LANCET of March 17th (p. 577), that he has never claimed that hydrocephalus is caused by inability of the choroid plexus to absorb the spinal fluid.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

II.—THE SOCIAL PROBLEM GROUP

THE most dangerous type of criminal is the one who turns in ordinary society and is accepted at his face value as a respectable citizen. So it is with defect. The potential parent who carries the seed of defect, unknown even to himself until it is too late, constitutes a more intractable problem than the individual who is outwardly and manifestly defective. This is the rock on which any proposals for sterilisation are liable to split.

A PARADOX AND ITS EXPLANATION

The evidence given before the Brock Committee goes to confirm the view that the proportion of mentally deficient persons among the parents of mentally defective children is remarkably small. Several independent investigators report that they failed to discover more than about 5 per cent. in this category. We need not search for any mysterious principle to explain this. The reason is precisely the same as that which determines why black sheep eat less than white—there are fewer of them. The ratio of defectives to carriers of defect, who much more commonly beget defective children, cannot be calculated exactly, but it is estimated to be in all probability less than 1 to 10.

It would, however, be an elementary error in logic to conclude that because defective children seldom have defective parents, therefore defective parents seldom have defective children. Yet this appears to be an inference that is not infrequently drawn. Some go further; they suppose that defect is akin to genius and that, by the sterilisation of persons liable to produce defective offspring, there would be considerable danger of robbing the world of great men. It may be pointed out in passing that such an argument would carry much greater weight if urged against milder methods of birth control practised by people who are intellectually well endowed. But in point of fact the alleged danger is exceedingly slight. On this subject also there is valuable new evidence in the Brock report. In a large sample of 3650 children born to parents at least one of whom was an ascertained defective, collected from different parts of the country, it appears that less than 1 per cent. could be classed as of superior intelligence, and over 40 per cent. were classed as defective or mentally subnormal. In another sample of about 1600 families from Merseyside, each containing a defective child, it was found that when both parents were normal 70 per cent. of the children were normal; when one parent was subnormal—including in this case the mentally retarded, the epileptic, and the insane, as well as those certified to be mentally deficient—the percentage of normal children fell to 57; and when both parents were subnormal the percentage fell to 41.

These figures indicate, and there are other strong grounds for believing, that intelligence (or the lack of it) is largely an inherited character. The first essential step, therefore, if mental deficiency is to be eliminated, is to discover some method of distinguishing the carriers of defect. Since to all appearance there is a continuous gradation of intelligence from the wise to the simple, and there is no clinical method for determining whether a borderline case is defective or not, it might seem a hopeless task to pick out the carrier. But this is not so, for though not certifiable as defective he is frequently subnormal in intelligence or comes from a subnormal class. The same investigators who are quoted in the Brock report as finding no more than 5 per cent. of defectives among the parents of defective children, state that at least 30 per cent. of the parents are persons of low intelligence. The Wood Committee, it may be recalled, discovered that a large number of defectives of the primary amentia type were found in quite a restricted group of families, a group including "a much larger proportion of insane persons, epileptics, paupers, criminals (especially recidivists), unemployables, habitual slum dwellers, prostitutes, inebriates, and other social inefficients than would a group of families not containing mental defectives." It has, in consequence, been termed the Social Problem Group, and the failure in life of the individuals who comprise the group must be attributed primarily to their poor mental endowment. It is possible, the Wood report states, that, although the majority of them are not so low-grade that they can be actually certified as defective, a not inconsiderable number might prove to be certifiable if examined by experienced medical practitioners.

ENVIRONMENT SUPPLEMENTS HEREDITY

These considerations suggest that the most fruitful soil for defect is composed of a mixture of bad environment and weak heredity. Too often in the past parties have taken opposing sides on this question and maintained that all the blame for the persistence of defect must be attributed to one or other of these two factors. For our immediate purpose it is less important to decide, if we could, which plays the chief part than to observe that they supplement each other at every point. To say that intelligence is an inherited factor is not to imply that environment counts for nothing. On the contrary, external conditions—the kind of home in which a child is nurtured and the class of school to which he is sent—have an immense influence in moulding his mentality and in determining what he makes of his talents. The more intelligent the parents, the greater is the chance that the children also will be intelligent; on the other hand, if the parents be half-witted or mentally retarded, the less likely are the children to have an environment calculated to bring out effectively such abilities as they possess. Informed opinion, supported by the investigations of Dr. F. D. Turner and Dr. L. S. Penrose at the Royal Eastern Counties Institution at Colchester, now rather favours the view that while a small proportion of defect is due to purely external causes, *and a decidedly larger proportion is due to* purely hereditary causes, many, and possibly the majority of, defective cases arise from a combination of the two, in the sense that the genetic seed will only result in defective fruit given a suitable environment. Certainly, in the present state of our knowledge, it is impossible frequently to disentangle the two factors. It must be understood that "environment" here includes prenatal influences, when the condition of the parent determines the environment of the child; this would go some way to account for the prevalence of defect in the social problem group. In the Colchester investigation a systematic clinical and psychological examination of the patients, coupled with an inquiry into their family history, suggests that in 9 per cent. of the first 513 patients examined defect was due to environmental causes alone, in 29 per cent. it was due solely to heredity, while in 62 per cent. it was held to be conditioned by a combination of heredity and environment.

FERTILITY OF THE SUBNORMAL

We have seen that the carrier of defect is not usually a normal person. He is most frequently found in a group that is definitely subnormal. Add to this that like is attracted to like. The dull tend to marry the dull and defective, with the inevitable result that defect tends to be cornered and concentrated in this particular class of the community. That may not be altogether a bad thing, because it is easier to cope with defectives who are to be found in clusters and not indiscriminately scattered.

But there is another aspect of the problem that is serious. Whereas low-grade defectives are usually confined in institutions or under the care of their relatives, so that they are not free to marry and beget children, there is no such control exercised over the majority of the individuals who make up the social problem group. Nor have they sufficient intelligence, foresight, or self-control to set a limit themselves to the number of children they produce. The consequence is that the fertility of this subnormal class is much above the average fertility of the normal population.[1]

AN EXAMPLE FROM MR. LIDBETTER'S COLLECTION

A concrete example will serve better than further argument to point the moral. It is taken at random from the valuable collection of pedigrees recently issued by Mr. E. J. Lidbetter,[2] and it is undoubtedly typical of conditions with which social workers are painfully familiar, although the first generation of the families concerned is larger than the families one commonly meets to-day, even in this class. Only a part of the pedigree is reproduced and it is presented here in form somewhat different from the original, but using the author's own description where possible.

The story starts with two parents, presumably of poor mentality, for they were stated to be living in deplorable conditions and from time to time they were dependent upon public assistance. They had 15 children of whom 3 were stillborn, 5 died in infancy, 2 at four years, and 2 others under twenty. Of the remaining three, two were low-grade mental defectives, one being also an epileptic who died in the workhouse at thirty years of age. The other defective, a female (F.), married a feeble-minded man (M.), but before considering the offspring of this marriage it will be of interest to examine M.'s family history.

Here we begin with a man who was committed to prison for some minor offence and there died. His widow was on poor relief for several years. They had 14 children of whom 8 died in infancy and at least 3 were reared in poor-law schools. One of these three children, a girl of low mental order, cohabited for several years with, and subsequently married, a man who came to London from a small village in the Eastern counties. His mental state is not recorded, but one might infer from his choice of mate that his intelligence was not bright. They had 10 children of whom 5 were born before marriage. The family wandered about from place to place in East London, so that it is impossible to give a complete account of their drain on public funds, but the known and measurable periods of their chargeability to various boards of guardians amounted to nearly 10,000 days. Five of the woman's children are known to have been born in workhouses, the last of them nine years after her husband's death, and all who survived, six in number, were reared or maintained intermittently in poor-law schools. M. was one of these six children.

It seems almost criminal that this mentally deficient couple, M. and F., each coming from a stock with such a deplorable record, should be permitted to unite in wedlock. Their first child, like his father, was born in a workhouse a month after the marriage. The father indeed had spent his life in poor-law institutions except for two periods, one of five years when he was in Dr. Barnardo's Homes, and one of four and a half years when he was in the Army Labour Corps. Only for very short intervals during the later years of the record did he and his wife leave the workhouse, but their brief freedom sufficed for them to bring six children into the world. Two of the children survived and these were reared in poor-law schools. Latterly it appears that the relationship of the couple became somewhat casual: the woman disappeared but she was known to be living an immoral and uncertain life in the common lodging-houses of East London.

A PROBLEM TO BE TACKLED AT ITS SOURCE

In this example there is no evidence of organic disease. We have simply a combination of poor mentality, high fertility, and sordid conditions. It is a weak policy simply to avert our eyes from the degradation of human life and waste of public money that such conditions imply. Sooner or later the problem will have to be tackled at its source. Means must be found of discouraging from parenthood persons of the social problem type, who are more than likely to give birth to children of feeble if not defective intelligence, to be a constant drag upon the community in their turn.

The proposal of the Brock Committee that voluntary sterilisation should be permitted to any parent who has produced a defective child is one that should commend itself to all as a step, though only a small step, in the right direction.

THE LANCET

LONDON: SATURDAY, MAY 19, 1934

CENTENARY OF THE LIVERPOOL SCHOOL OF MEDICINE

It was in 1834 that a grand old band of workers organised systematic lectures, covering eight medical and premedical subjects, in rooms belonging to the Liverpool Royal Institution; and to celebrate the foundation of this school of medicine just a hundred years ago, Prof. John Hay delivered an oration on Friday last in St. George's Hall, where the first infirmary once stood. The school from its start was coloured by its proximity to a famous port. An Act of George III. required every ship in the African trade (at that time mostly in slaves) to carry a surgeon qualified at Surgeons' Hall or by examination at a county hospital, and the infirmary had risen to the occasion by examining candidates at its monthly board meeting and passing nearly five hundred young surgeons into this service between the years 1789 and 1807.[1] Facilities for medical education at the beginning of last century were limited to schools attached to four London hospitals, no body of teachers outside the metropolis being permitted to grant degrees; nor did their lectures entitle students to enter for the examination of the Society of Apothecaries, until in 1821 this barrier against provincial teaching was broken down in Manchester, Liverpool soon following suit. At that time Liverpool was, it is said, the only town of any pre-eminence in England without one single erection or endowment for the advancement of science, and there was a chasm between the money-makers and a population of 100,000 workers packed more densely than anywhere else in Great Britain.

William Roscoe gave the lead to the select band of medical men who were not content to be absorbed in this nautical vortex. The turn of the century saw the foundation of the Athenæum, the Literary and Philosophical Society, and the Liverpool Medical Library; in 1817 was founded the Royal Institution which had among its aims that of providing lectures on chemistry, botany, anatomy, surgery, and medicine. There were not lacking other local names of outstanding merit, for it was Matthew Dobson who, in 1774, first demonstrated the presence of sugar in diabetic urine, and his colleague, Henry Park, was a pioneer in surgery of the joints. Things were made easier for medical study by the passing in 1832 of the Anatomy Act, providing an adequate supply of bodies for dissection, but not much progress was made until 1844 when the medical school was transferred from the Royal Institution to buildings erected by public subscription near the infirmary on its new site in Brownlow-street. Here the two grew up together, the school enjoying the protecting care of the infirmary. It remained, however, without endowed chairs, one faculty only with lecturers in science, until in 1874 the new regulations of the University of London compelled the council to extend its teaching of science, and this led to the establishment of University College. The sequence of events was quite different in the two great Lancashire towns. Whereas Owens College, Manchester, founded in 1851, had no faculty of medicine until 1873 when it became incorporated with the school of medicine, in Liverpool the development was in the reverse order; it was the lecturers of the medical school who took the initiative in the formation of University College, and it was the medical school of the Royal Infirmary which formed the core of the university. For many years the faculty of medicine was the most active and progressive of all the faculties. The first chair to be endowed was that of physics, first occupied by Sir Oliver Lodge, and other endowed chairs were held by such men as Campbell Brown, Herdman, Gotch, Paterson, Boyce, Sherrington, Benjamin Moore, and Ronald Ross. To match these giants on the academic side Liverpool was equally fortunate in having such clinicians as T. R. Glynn, R. Caton, W. M. Banks, F. T. Paul, W. Carter, Wm. Alexander, Rushton Parker, James Barr, and Robert Jones.

In other directions the presence of the port exerted a profound influence over the development of medicine in Liverpool, for in 1898 through the enthusiasm and foresight of Sir Alfred Jones, fortified by Sir Rubert Boyce, was founded there the first school of tropical medicine in the world. This school received its charter in 1905 with seats on the faculty of medicine. At that time there was scarcely any systematic investigation of tropical disease, the ground was almost virgin soil, and on the very first expedition Major Ross cabled from Sierra Leone on August 17th, 1899, to say that the malarial mosquito had been discovered. Next year, Dr. Annette, in Nigeria, proved the transmission of the parasite of elephantiasis by another mosquito, and up to 1914 no less than 32 expeditions were sent out to the tropics to study disease and sanitation. Another chair of which Liverpool is justifiably proud, that of biochemistry, the first in the British Isles, was created for Benjamin Moore, not only brilliant as a biochemist but possessing an infective enthusiasm. It was in his department that the *Biochemical Journal* saw the light. But the Liverpool school is not content to rest on its laurels. Disease, said Prof. Hay, is for ever taking new forms in changing conditions of life and society; the price of victory is eternal vigilance, the best defence is vigorous attack. Now is the time to strengthen the research activities of the clinical chairs and to found yet another chair in clinical science. And no doubt that will be done.

---

[1] Many interesting details are given in "A Brief Record of the Liverpool Medical School, 1834–1934," by Arthur A. *Gemmell, M.D.* (Liverpool: The University Press. Pp. 22. 1s.), based on a vice-presidential address given to the Liverpool Medical Students' Debating Society on Jan. 18th last.

THE PROMOTION OF UTERINE CONTRACTIONS

WITHIN recent years a score of papers have been published by German, French, British, and American workers concerning the mechanical recording of the contractions of the human uterus. Three devices have been used—namely, an adaptation of the electrocardiograph, secondly, an apparatus recording changes in the shape of the abdominal wall consequent on uterine contractions, and thirdly, an intra-uterine bag connected to a recording manometer. The first method has been tried by German workers but has not yielded very useful results. The second in various forms has given some useful information, while the third, obviously the most direct, has given reliable and consistent results although at the expense of discomfort, and possibly some risk, to the patient. The most recent contributions to this subject are those by F. L. ADAIR and M. E. DAVIS [1] from Chicago, and by CHASSAR MOIR [2] from this country.

The communication by the American workers appears to be an interim report on the results obtained in the limited number of cases so far examined. The experiments, in which an intra-uterine bag was used, fall into three groups: (1) those made before or during labour; (2) those made in the immediate post-partum period, and (3) those made in the later puerperium. In groups 1 and 3 the methods used were similar to those which have been described by BOURNE and BURN, and by MOIR in this country, and more generous acknowledgment might appropriately have been made to these workers; in group 2 the observations were made immediately after a low segment Cæsarean section, a hydrostatic bag having been inserted into the upper uterine segment during the operation and the attached tubing brought out through the vagina. Under these conditions the upper uterine segment was always active and would respond to oxytocic drugs, while the lower segment (into which the intra-uterine bag could be pulled) was inactive and non-responsive. This corroborates the views usually held regarding the functions of those two portions of the uterus. MOIR, on the other hand, records different results from somewhat similar experiments performed late in the puerperium. He introduced a double bag into the uterus on the seventh day of the puerperium, one portion lying in the body of the uterus and the other in the reconstituted cervical canal. It was found that contractions were recorded by both bags; in some cases these were coördinated, the cervical canal contracting about 17 seconds after the fundus and thus suggesting a peristaltic action of the uterus.

ADAIR and DAVIS, the Chicago workers, have been chiefly concerned with the action of pituitary extracts, and of drugs on the uterus before and after delivery. They are not enthusiastic about the various ergot preparations, since the records so far obtained suggest that their effects are very inconstant. Ergotamine in the form of Gynergen (better known in this country as Femergin) yielded no result when given by injection. These observations do not correspond with those of MOIR,[3] who found that contractions could be constantly recorded after injection of ergotamine or ergotoxine, and also after oral administration of B.P. liquid extract of ergot. He has recently confirmed these results,[2] and states that whereas the ergot alkaloids take half an hour or more to act after injection, liquid extract of ergot acts within a few minutes of administration by mouth. This effect is presumably due to an unidentified active principle which is present in crude ergot preparations. The action of histamine is also discussed in both papers. This substance has hitherto been held to enhance the action of the ergot alkaloids, and to be a useful addition to such drugs; BOURNE and BURN obtained tracings showing that histamine has a quick oxytocic effect on the parturient uterus. According to the present workers this is true of large doses only, as far as the puerperal uterus is concerned; when quantities small enough to avoid serious vaso-motor disturbances are given (2 mg. of acid phosphate or less), the uterine action is negligible. Quinine, too, has given no certain evidence of oxytocic power on the parturient or puerperal uterus—an observation previously made by S. M. DODEK,[4] and by MOIR. Clinicians will probably feel that a fuller investigation should be made before these negative findings are accepted.

Perhaps the most interesting aspect of the work at Chicago concerns the action of the separated oxytocic and vaso-pressor principles of the posterior pituitary gland. It was found that for intravenous injection during pregnancy or in the puerperium, pituitrin, pitocin, and pitressin were equally effective. This is a remarkable observation, contrary to the findings of BOURNE and BURN [5] in their work on the uterus at term. Some variation of technique such as the use of intravenous instead of the more usual intramuscular injection may possibly account for the discrepancy in results. Unfortunately the information given by ADAIR and DAVIS on many essential details is disappointingly vague. For example, in several places the dosage of a solid substance is expressed in fluid measure without a note of the strength of the solution used; pituitary extracts are measured in minims without reference to the number of international units in the dose; and there is no indication whether the dosage of histamine is recorded in terms of the relatively heavy acid phosphate, or of the pure substance. This lack of precision makes it rather difficult to ascertain to what extent their results conflict with those obtained elsewhere. Other significant observations have, however, been made concerning the uterine action of the pituitary extracts. ROBSON,[6] working with muscle strips obtained from the human uterus at various stages of gestation, has shown that there are three stages of reactivity: (1) an early period when the uterus s non-reactive to both oxytocin and to vasopressin; (2) an intermediate period when the uterus reacts to vasopressin but not to oxytocin; (3) a late period when the uterus is highly reactive to oxytocin. DATNOW and JEFFCOATE have obtained somewhat similar results. Meanwhile, MOIR, using a new apparatus for recording clinically the contractions of the human non-pregnant uterus, reports[2] that there is no response to an intramuscular injection of 10 units of oxytocin, whereas a well-marked uterine spasm follows injection of 10 units of vasopressin. It is clear that the uterine action of these extracts is far more variable than their names would lead one to expect; the nature of the response appears to depend on the biological state of the organ at the time when the extracts are administered.

Pursuing further the study of the non-pregnant uterus MOIR has shown that the muscular activity varies with the stage of the menstrual cycle—the contractions, slight at first, becoming increasingly powerful towards the end of the cycle, and reaching a maximum in strength and frequency during menstruation. Hitherto gynæcologists have been chiefly interested in the cyclical changes in the structure and function of the uterine endometrium. It would now appear that a regular variation of activity takes place also in the uterine muscle. Such observations have an obvious bearing on the problems of dysmenorrhœa.

THE PROFESSIONAL MIND

LORD MACMILLAN, one of the happiest of our public orators, delivered this week the annual Maudsley lecture of the Royal Medico-Psychological Association. He chose for his subject the Professional Mind and discussed it not only to the evident enjoyment of his hearers but also to the prospective profit of a wider circle. Nobody will deny that the choice and practice of a profession visibly mould the mental outlook of men and women. In the process their habits are controlled, their thoughts are canalised, and their prejudices are developed; the very district of their activities, be it the neighbourhood of Cavendish-square or Chancery-lane, is determined by their vocation. Those who practise a particular art are drawn apart; they constitute a separate fraternity. In professional life, as in other kinds of life, there are elements good and not so good. There is material for praise wherein we may complacently take pride; but we must not expect even the most discreet and courteous of candid friends to be blind to our shortcomings and to have nothing to tell us to our advantage. Immersion in a profession has its risks. One of them, Lord MACMILLAN warns us, is the inevitable tendency to resist all change. Having painfully mastered a system, we are disinclined to scrap what we have found to work well enough. It is not easy to make the effort to examine new ideas which may prove uncomfortably subversive. A century ago, we are told, the Admiralty felt it to be its duty to discourage the introduction of steam as calculated to strike a fatal blow at the naval supremacy of the Empire. Has the history of medicine no instances of a similar conservatism? Another danger of the professional outlook is the proneness to prefer the interests of the craft to the interests of the community. ADAM SMITH indeed looked with profound suspicion upon professional and trading corporations. "People of the same trade," he observed, "seldom meet together even for merriment and diversion, but the conversation ends in a conspiracy against the public or in some contrivance to raise prices." Citing this gloomy comment by his great compatriot, Lord MACMILLAN wonders what SMITH would have thought of the innumerable congresses and conferences nowadays held by every trade and calling. "I am afraid," he adds, "he would often find in a perusal of their proceedings little to dispel the truth of his indictment." Yet the community never needed the expert so much as now. In the planning of industry, whether it be coal-mining or agriculture, in the coördination of facilities, whether it be water-supply or London transport, there is a demand for the expert to be put in charge. The experts are not, however, unanimous, nor are they infallible. The faith of the public in political economists, for example, has, as Lord MACMILLAN says, been rudely shaken by the discordant advice which they have tendered since the war for the treatment of the ailments of the body politic. Post-war or pre-war, the Adam Smiths no longer have things all their own way.

To the professions of medicine and of law, producing perhaps a comparable type of mind, Lord MACMILLAN devoted special attention. The lawyers, he confesses, are sometimes accused of sacrificing conscience to advocacy, of thriving in an atmosphere of forensic red herrings and of overworking their faculty of making the worse appear the better reason. While not blind to the elements of truth in the popular caricature, he still can claim with confidence that the practice of the law has no deteriorating effect on the moral character. The great bulk of the legal work of the country, he says, is non-contentious; it requires for its successful performance no perverse intellectual subtlety but simply the ordinary workaday virtues of industry and honesty. Lawyers, he admits, tend to be preoccupied with words, to worship a formula, to value an argument not so much for its essential soundness as for its convenience of statement. They tend too to cynicism and to criticism of a merely destructive sort. "This critical habit is a useful quality in its proper place but it often handicaps the lawyer in dealing with constructive proposals where success can be attained only by disregarding risks. And so lawyers are not temperamentally well-fitted for leadership either in politics or in business, in both of which spheres an adventurous spirit is essential; they may be admirable in deliberation, they are not so useful in action." If the lecturer discreetly refrained from naming twentieth century examples, some of his hearers probably allowed themselves a greater licence in secret. An audience of doctors indeed might make bold to remember that, while the post-war period has piled up special difficulties for the Ministries of Health and Agriculture, two of the most vigorous and constructive of our political leaders have been members of the medical profession.

Turning to a study of the doctors, Lord MACMILLAN acknowledged that their relations with their patients reveal an intimacy which no other profession attains, and that diagnosis requires not only knowledge but also reasoning power and imagination. Personality, again, counts for much in medical practice; the mere presence of the trusted medical adviser inspires confidence and has its own therapeutic value. The exacting nature of the work, the irregular hours, and the frequent interruptions of ordinary social life are other forces which, making their demand upon the whole physical, mental, and emotional resources of the doctor, create a special type of character. The type, Lord MACMILLAN reminded his audience, is exemplified in the highest degree in those who are called to minister to minds diseased—a region of practice where psychological factors necessarily predominate. What is that type, or rather perhaps what should it be? The lecturer made no attempt to preach a lay sermon on medical ethics. He merely gave us for the moment the gift to see ourselves as others see us. Despite his continual contact with suffering, the doctor, as Lord MACMILLAN sees him, is not callous. He must acquire a certain calmness in the presence of life's emergencies and tragedies which is not to be mistaken for unconcern. Despite the confidence reposed in him, he will resist the temptation to be professionally oracular. Despite his habit of setting out prescriptions in hieroglyphics, he will remember to avoid the obscurantism of spells and incantations. Foibles can be laid to the charge of his vocation; they are to be outweighed by the unselfishness and devotion to duty which Lord MACMILLAN generously describes as the very hall-mark of the medical profession. "It is perhaps in the medical man," he concluded, "that the professional mind finds its finest flower." Though we may feel the praise to be too charitable, we can thank him warmly for a stimulating re-statement of the ideal.

ANNOTATIONS

ROYAL SOCIETY CONVERSAZIONE

THERE were 51 exhibits at Burlington House on the evening of May 9th illustrating, it is said, the most recent advances in pure and applied science, but affording a still better illustration of the fact that the exhibitor may be of as much interest as the exhibit. It is one of the attractions of the evening that those who explain the advances have contributed in large measure to the advance. There were, it is true, only two exhibits bearing directly on medical practice, although few, if any, had not some indirect relation to it. Exhibit 15 consisted of bed bugs to illustrate the possibility of their control by fumigation when furniture is in transit from old slums to new estates. Exhibit 31 was a model of the simple apparatus for artificial respiration which kept a patient alive for two years in the account given in our own columns on April 14th, p. 786. The physiologist had an opportunity of seeing a successful attempt to keep electric responses from a nerve constant during stimulation by condenser discharges; he could follow the detection of acetylcholine by its action in extremely low concentration on different kinds of isolated muscle. The pathologist was shown the coccoid organism responsible for psittacosis and the cytoplasmic inclusions seen in other virus diseases such as canary pox and dog distemper. A demonstration was given on a microscope for ultra-violet photography in which the optical parts must be standardised with such care that they are interchangeable. Those with a historical turn were shown the first telescope with an erecting eye-piece made by Maria de Rheite and dated 1646; the magnification is about 21 and the telescope is in its original condition and still perfect. They were also told the story of the automatic microtome devised by undergraduates at Cambridge in 1882 and still the basis of the famous "rocker." Geneticists could see a remarkable race of oat plants having 41 instead of the normal 42 chromosomes, producing progeny 88 per cent. albino and incapable of living more than a few weeks; also how irradiation might produce breakage and fusion of chromosomes in locusts, resulting in many-tailed sperms. The physicist was shown the apparatus for photographing a lightning flash no matter what its speed, and the means for determining the length of the metre and the yard in terms of wave-lengths of light. And finally all who go down to the sea were gladdened by an exhibit by the Admiralty Chemical Service of a means for salvaging waste oil and so avoiding the terrible mortality of marine birds. Altogether it was an exhibition to stimulate the imagination.

OPERATION IN PNEUMOCOCCAL PERITONITIS

No final answer has yet been given to the question whether or not operation is the best treatment for cases of pneumococcal peritonitis. Against surgical intervention it has been argued that it is not only dangerous and characterised by a high post-operative mortality, but is also useless because it is not possible to remove the cause of the infection. MM. Loutsch and Mérigot have recently challenged [1] the basis of these arguments, although they admit that the main reason for operative treatment is the extreme difficulty, often amounting to impossibility, of deciding between peritonitis due to appendicitis and pneumococcal peritonitis. This is where the argument is apt to end in practice. Loutsch and Mérigot have been at some pains to analyse the signs and symptoms of pneumococcal peritonitis in ten cases which have come under their care in the Hôpital Trousseau. No sign or symptom was found which proved of any constant value. Herpes of the mouth was an important sign when present, as was vulvitis. Diarrhœa they do not consider pathognomonic, although it was present in several cases. Generalised abdominal pain is not of much value, as quite often the maximum pain was referred to the right iliac fossa, and there was no sign elicited by examination that was of any particular assistance. The most characteristic finding in these ten cases seems to have been the profound illness of the children. Every case has some such observation as "general condition grave," "cyanosis," "respiration quick," and the pulse-rate varied between 120–150. One characteristic sign, not mentioned by these authors, but which may prove of great value in diagnosis is the grunting nature of the respirations. This is apparently a sign of pneumococcal septicæmia, as it is present in pneumonia, as well as in pneumococcal peritonitis. But if it is hard to determine whether operation will do any good, Loutsch and Mérigot find no reason to suppose that it influences the prognosis for the worse. The mortality is admittedly high (they give it as 30–50 per cent.), but this they consider is attributable to the nature of the disease. Their observations on the course of the illness have led them to recognise a critical period between the 10th–15th days, and, in common with other observers, they distinguish a type of case in which peritonitis is but one of several manifestations of a generalised disease. These cases have a very serious prognosis. Answering the contention that operation (by which they really mean drainage of the peritoneal cavity) is useless, they quote observations of their own to show that improvement in general condition followed free evacuation of pus. To say that operation is futile if one does not remove the source of the infection is no more valid here than in many other diseases in which drainage is of proved value. Even before pus has formed they advocate peritoneal drainage, for pus may drain away later. With the more vital objection that so-called drainage of the peritoneal cavity drains only a small cavity around the tube, they do not deal, nor do they consider the view that late drainage of pus may be due to secondary infection of the depths of the wound from outside. The question resolves itself, as it always does, into whether it is possible to exclude acute appendicitis, and whether, in operating to settle the diagnosis, we are prejudicing the chances of recovery in the case of pneumococcal peritonitis. Loutsch and Mérigot would operate.

EPIDEMIC VERTIGO

Dr. Stefan Vatev, who holds the chair of pædiatrics at Sofia, has recently described[1] epidemic vertigo as he has seen it himself in Bulgaria, and his account confirms in its main features that given in our correspondence columns a few months ago by Dr. Otto Leyton.[2] In the autumn of 1929 Dr. Vatev began to see cases of a peculiar disturbance of consciousness, best covered, he thought, by the term vertigo, attended with a characteristic group of accompanying symptoms. The onset was sudden, the duration several days or weeks, the victims as a rule being able to go about their work the whole time. In three years he saw 146 such cases—62 males, 84 females, at all ages—without predilection for occupation, although six doctors were among the number. As a typical example he tells of a doctor, aged 65, who in February, 1930, became suddenly aware of giddiness on moving his head when recumbent. The giddiness was accompanied by a feeling of heaviness in the stomach and twice he vomited before rising in the morning. He was apt to feel giddy on rising from his seat or on bending his neck to auscultate; he had occasional palpitation with no alteration of blood pressure; he complained now and then of headache, especially in the forehead, was troubled with polyuria chiefly at night, with no qualitative alteration in the urine. The attacks lasted three months and then disappeared, along with the cardiac irregularity; four months later he had left-sided hemianopia lasting a month. He tried all kinds of drugs without appreciable effect, except that aspirin relieved the nocturnal polyuria. In this doctor's household his mother-in-law had similar but slighter symptoms lasting a fortnight in May, 1930, repeated again in November. His 20-year-old daughter had slight vertigo, pain in the neck, heaviness in the stomach, and nausea, the symptoms only present on getting up in the morning and lasting two months. In October the doctor's wife had attacks of vertigo when recumbent at night, accompanied by radiating pains over the heart. Two sons of 22 and 27 were the only members of the household who escaped. The other cases were of much the same character, often occurring in groups; the vertigo mostly coming on at night or at all events in the recumbent position, and rarely preventing the subject getting about. In a few cases there was complaint of definite loss of consciousness not lasting more than a few seconds but giving rise to a feeling of insecurity. Headache was frequent but only severe in nine cases of which a few had hemicrania. Some patients complained of muscular cramp during sleep, others of myalgia. Dr. Vatev remarks that a rise of temperature had no effect on the severity or the frequency of the vertigo; even when influenza was prevalent in the spring of 1931 the cases of vertigo kept on occurring without relation to it. In no case did the attack leave any sequel. Diminished patellar reflexes were noticed in some cases. Both epilepsy and hysteria could be definitely excluded. The occurrence of the disease in groups led Dr. Vatev to regard it as an infection with a specific neurotropic virus, but as to where it enters the body and how it produces its effect he ventures no opinion except that the probable port of entry is the nose and throat.

THE MICROSCOPY OF VIRUSES

THERE is abundant evidence that the larger filtrable viruses can be seen with the microscope. Recent work with vaccinia, fowl-pox, psittacosis, and ectromelia fully justifies such a statement. Not only can formed elements be seen in stained preparations of virulent material, but these virus particles can be freed from extraneous material by differential centrifugation or ultrafiltration and shown to be both virulent and susceptible of specific agglutination. Only the ultraphilosophic remain reluctant to abandon the possibility of these particles being merely the inert carriers of an unorganised virus, and their attitude is hard to understand, particularly when one recalls that Barnard's findings with ultra-violet dark-ground microscopy have shown the particles to have definite structure.

This line of virus research it now being actively pursued in Japan, and in two recent papers[1,2] Taniguchi and his associates describe new methods of staining and the fruits of their application to the study of the viruses of vaccinia, fowl-pox, molluscum contagiosum, varicella, herpes simplex, and zoster. So far, however, it cannot be said that the work substantially advances our knowledge; even the method of staining, which depends on mordanting with an acid dye like eosin, has already been suggested by Craigie.[3] Moreover, some of the conclusions arrived at in the first paper are open to question. The virus of varicella was studied in rabbits—a species whose susceptibility to this virus has never been established—so that the conclusions that it multiplies in the cytoplasm of infected cells can only be accepted with caution. The statement, too, that the viruses of fowl-pox and molluscum multiply preferably in the nucleus is almost certainly incorrect; even two out of three of the authors' illustrations, viz., Fig. 3, of cells infected with fowl-pox virus show the inclusion in the cytoplasm, while the third is so indefinite as to leave one in doubt as to whether one is dealing with a virus inclusion or not. The second paper is devoted to the viruses of herpes simplex and zoster. Here again there is evidence of unfamiliarity with published work. The claim to priority in the discovery of zoster elementary bodies ignores the fact that Paschen[4] has described and figured these bodies, and the estimate of 0·25 μ for the size of herpes simplex is not in keeping with the work of Bedson [5] and Elford, Perdrau, and Smith [6] to which no reference is made. It is unfortunate that the enthusiasm of the Japanese investigators should not have been tempered by fuller knowledge of what has been done elsewhere.

THE R.I.P.H. AT NORWICH

THE annual conference of the Royal Institute of Public Health, held under ideal conditions at Norwich during the present week, was opened by a remarkable address from the President, ex-Lord Mayor Henry M. Holmes, on the conditions of employment in that city over a period of six hundred years. Norwich rose to prosperity when Edward III. and his Queen brought Flemish weavers to initiate the trade in wool and worsted, which remained the staple industry until the machine loom in the industrial north spoiled the market for handmade goods, when even the weavers themselves could not afford to buy their own produce. In the sixteenth century Flemish refugees introduced the dyeing and printing of fabrics along with new forms of weaving, and prosperity was accompanied by a high sense of social hygiene, for the city had a piped supply of water to the market as well as to private houses and it is recorded that the streets were so well kept that they maintained the health of the citizens and won the praise of strangers. Still in the eighteenth century Norwich was without a rival in the art of dyeing, and worsted fabrics were sent there from all parts of the country to be dyed and finished. Even children from six to ten years "gained twelve thousand pounds more than what they spend and that chiefly by knitting fine jersey stockins"; every weaver too had a goose for his Sunday dinner. When industrial prosperity declined in the early nineteenth century the public health also ebbed; streets were badly paved and lighted, with an almost complete lack of drainage, courts were the dumping ground for refuse, and in the worst neighbourhoods there was little water as the tenants could not, and the landlords would not, pay for it. Later in the century the familiar tenacity of Norwich folk reasserted itself and the making of boots and shoes again brought prosperity to the city, which even dictated the fashion in light shoes. Edible and household commodities of all kinds were manufactured at Carrow, and Norwich became emphatically a town of mixed industry, although maintaining some of the characteristics of a mediæval city. At the conclusion of his address Mr. Holmes gave illustrations of the high degree of social welfare among the present-day workers, of a vast scheme of municipal housing, and of the development of public services by which, in the words of a handbook recently issued for tenants on the housing estates, "the ratepayer can be born in a municipal maternity home, cared for in a creche, and be educated, doctored and generally reared in a public elementary school, supported during his manhood in time of need, and buried in a public cemetery." The conference was honoured by the presence of Sir Charles Sherrington, who was awarded the Harben gold medal for distinguished service in physiology.

"OCCUPATION AND HEALTH"

THE final number has just been issued by the International Labour Office at Geneva of the English edition of the valuable encyclopædia, entitled Occupation and Health,[1] which has been appearing in brochure form at irregular intervals for the past ten or twelve years. The completed work consists of 353 articles, each contributed by an expert of international standing. It appears in English and French editions; as the articles were written originally by the authors in their own languages, often using terminology peculiar to some unique trade process, the task of translating such highly technical descriptions, together with pathological findings, has called for expert translators who have carried out their difficult work with great care. For example, only familiarity with the intricacies of metal smelting and with recent studies of pulmonary pathology could have enabled the last article in the series which deals with zinc to be successfully translated. The plan of the book is this. In each instance industrial usage and processes are described with explanations of exposures to hazards, whether from some toxic agent or bodily strain; then follow sickness records and pathological descriptions with preventive measures and treatment, concluding with legislation. Some idea of the scope of the whole may be gathered from the subjects covered in this last brochure: transport industry, tripe and gut works, tungsten, turpentine, uranium, vanadium, varnishes and lacquers, welfare workers, wine and spirit industry, xylene, zinc. In 36 pages are considered the risks of transport, whether by rail, tramway, or load carrying; information has been gathered from Italy, Australia, U.S.A., Great Britain, Russia, France, Switzerland, Germany, Japan, Argentine, and Chili. The value of such a work for reference needs no emphasis.

DEFENCE AGAINST STAPHYLOCOCCI

THE paper by Dr. Parish and his colleagues on another page of this issue draws attention once more to the properties of staphylococcal toxin and toxoid. It is shown that in laboratory animals injection of these substances will increase the amount of antitoxin in the serum, and that the presence of this antitoxin is of real value in combating infection with the living staphylococcus. It is also shown that the use of toxoid in man leads to an increase in the amount of circulating antitoxin; the clinical results, however, are left somewhat vague. It is unfortunately true that, although many accounts of such treatment have been published in the last few years, its value is still uncertain. This is evident, for example, from two reports which have appeared in the last few weeks. In the first, D. J. Kindel and M. J. Costello [2] describe the effects of treating a mixed series of skin infections with toxoid; more than half of the cases were diagnosed as acne vulgaris and the results were naturally disappointing. In the second, J. A. Gilchrist and Mary J. Wilson[3] associate the incidence of diabetes mellitus with staphylococcal infection, particularly of the nasal sinuses, in many of their patients, and record cases in which treatment with toxoid has enabled them to dispense with the use of insulin.

In view of the misery caused by "trivial" but recurrent staphylococcal infection, and the potent effects in animals of modern preparations of toxin, the time seems to have come when a full investigation should be made into the effects of toxoid treatment in the various types of this infection. In such an investigation the use of a standard technique for the estimation of antitoxin, such as that quoted by Parish, O'Meara, and Clark, would probably be essential. Their paper is, however, open to criticism on a point which may be of real importance—namely, that it ignores the presence in toxin of a leucocidin capable of attacking human phagocytes. There is evidence suggesting that the production of leucocidin by different strains of cocci varies independently of the production of hæmolysin and necrosing toxin, and that the former property runs parallel with the severity of the human lesion from which the strain was isolated, whereas the latter does not. If this is true, the toxoid used clinically ought to be prepared from toxin in which both factors are present.

THE CONTROL OF BODY TEMPERATURE

THE recent advent into therapeutics of artificial pyrexia brings into prominence the question of the normal control of body temperature. Although the principles of this are fairly well understood, it is probable that new lines of investigation will have to be explored before the implications of electro-pyrexia can be fully worked out. It is known that a steady temperature is maintained by an exact balance of heat production and heat loss, both of which seem to be under reflex control. It is convenient to regard heat as a by-product of muscular contraction; the contractile machine is not a perfect one, and mechanical energy can only be obtained from food at the expense of considerable wastage in the form of heat. During severe exercise the body must rid itself of this heat as best it can; an individual walking at five miles an hour may have to get rid of seven times as much heat as if seated. The body at rest is faced with a different problem, that of ensuring a degree of general muscular contraction sufficient to prevent its temperature from falling. This it does by adjusting the tone of the muscles; the "relaxing" qualities of warm air and the "bracing" effect of cold are commonplaces, while shivering may be regarded as an extreme form of involuntary muscular action called into play when simple increase of tone becomes insufficient. Of the significance of heat produced by the activity of other tissues we know little.

In heat loss by far the most important organ concerned is the skin, which is cooled partly by radiation and conduction, partly by evaporation. The former is controlled voluntarily by clothing, involuntarily by the amount of blood allowed to flow through the cutaneous vessels, and is naturally influenced by the temperature and movement of the surrounding air. The latter is controlled involuntarily by the activity of the sweat glands, and is profoundly affected by the humidity and movement of the atmosphere. Of the two, evaporation is more important during exercise and at high external temperatures; and radiation and conduction are more important at rest. Under normal conditions production and loss are balanced one against the other and may be called into play reciprocally. This dual control is important in relation to internal as well as external conditions. Far more fuel may be supplied to the body at one time than at another. If an excessive amount is taken as much as possible must be stored as carbohydrate and fat, and the surplus heat produced by the compulsory oxidation of the remainder (usually protein) eliminated via the skin. Conversely, insufficient fuel must be compensated by a call on stored food and even on the tissues themselves. All this is automatic, but a realisation of the underlying principles is important in arranging diet and clothing when there may be exposure to extreme climatic conditions; the tragic end of Scott's last antarctic expedition was due in part to the failure to realise the disproportionate amount of food needed to maintain body temperature over and above that required for strenuous work.

The balance of heat income and expenditure is clearly a matter of delicate reflex control, and it is not surprising that diurnal variations occur, nor that the body temperature rises during muscular exercise; it is in fact doubtful whether these are due to "failure" of control, or whether they serve some useful purpose. The menstrual fall of temperature in women, together with many animal experiments, points to the participation of the ductless glands in the process. A consideration of variations above and below the conventional "normal" temperature brings us to a further question. Once we have admitted that the balance between production and loss is not always machine-like and precise, we are forced to postulate some supreme entity which fixes the mean level and dictates how much ground must be ceded or regained at any given time in order to return to it. This function is attributed to a "temperature regulating centre" whose location is a matter of doubt; removal of parts of the brain in animals from above downwards indicates that it is higher than the mid-brain, and the corpus striatum has now given place to the hypothalamus as its most probable site. The reason why the mammalian temperature should have to be maintained about the level of 38° C. is a matter for speculation; in the course of the ages the sea must have passed this point in cooling to its present temperature, and its passage may represent a critical period in the history of warm-blooded animals.

The point of immediate interest is not, however, the normal temperature, but the limits which are compatible with life. From data given by F. Vlès[1] for a number of animal types, including some marine organisms, the commonest lethal temperature appears to lie between 38° C. and 45° C.; that of the dog, the only mammal mentioned, is 44°–45° C. which fits in with general experience in the human subject; yet some tropical animals have a normal temperature higher than this. In general animals have narrower limits than plants, and highly organised animals the narrowest of all. A list of common bacteria shows that these can withstand for a short time temperatures ranging from 54°–70° C., while some spore-forming varieties are not killed by temperatures well over 100° C. Dehydration (as in spore-formation) is shown by other examples to confer a great immunity to high temperatures. The *Treponema pallidum*, however, as previously noted in these columns[2] succumbs after exposure to 42° C. for one hour. The lower limits of temperature show a much wider variation; bacteria and seeds have been reduced to temperatures in the region of − 200° C. without being killed. For other plants about − 17° C. is fatal; for some fish and frogs about − 3° C.; for macaques + 14° C. and for man + 24° C. It should be emphasised that all these temperatures refer to actual tissues and not to the surrounding medium; the length of time for which they can be withstood is not given in all cases, but a sufficiently clear idea is obtained for comparative purposes. Vlès himself writes:—

[2] THE LANCET, March 31st, p. 695.

> "It seems that the temperature of coagulation of the protoplasmic colloids determines the irreversible thermal limit; but in reality disturbances are manifested long before the temperature of gross coagulation of the isolated proteins is reached. A whole series of physico-chemical mechanisms is affected by a rise of temperature . . . electrolytic dissociation . . . viscosity . . . colloid equilibrium and permeability . . ."

Liquefaction of fats and lipoids may occur, mitochondria may disappear, and marked change of reaction may supervene as a result of interference with the tension of carbon dioxide and its equilibrium with bicarbonate.

In addition to this there is the probability of establishing a vicious circle; increase of temperature stimulates metabolism, and this in itself produces internal heat. Although poikilothermic animals may have a rudimentary temperature control, directed in the main to combating low temperatures, it is unlikely that this is vested in the individual cells or tissues; as in warm-blooded animals it is probably a reflex phenomenon in which the animal as a whole is concerned. In other words, the passively heated tissue is not only defenceless, but even assists in its own destruction.

FOOD STANDARDS

THE British housewife, although she may not have much knowledge of the principles of nutrition, makes her purchases with considerable skill, having regard to the dietary, tastes, and customs of different parts of the country. This we have on the authority of a departmental committee on the composition and description of food which has just reported [1] to the departments of health. And her choice is no doubt made easier by the fact, duly noted in the report, that a large proportion of the food manufactured in this country reaches a high standard of quality. Nevertheless, the absence of definition does give rise to difficulties to consumers and administrators as well as to public analysts. The composition of certain articles of food is already regulated by law—e.g., spirits, flour, bread, butter, margarine, condensed and dried milks; and owing to this no doubt is the observation that the term butter has the same meaning in commerce to-day as it had fifty years ago, whereas toffee is no longer a sweetmeat prepared from butter and sugar—even if, as the committee suggests, purchasers are still getting what they want. The purchaser of cheese or cream gets articles with varying proportions of fat, for there is no statutory limit in either case. The position is vastly different in some of the Dominions where in South Africa, for instance, the number of food articles with exact legal definition and standard is about 50, and in Canada at least three times as great. The committee was asked to consider: "whether it is desirable that the law relating to the composition and description of articles of food should be altered so as to enable definitions or standards to be prescribed, or declarations of composition to be required, for articles of food other than liquid milk; and if so to recommend what alterations of the law are required."

On this main question the committee reports that it is desirable that the law should be altered in the way suggested, the enabling power being vested in the Ministry of Health for England and the Department of Health for Scotland. It does not consider that a case has been made out for the extension of standards or definitions to all articles of food. The Society of Public Analysts and a number of other witnesses were in favour of having a permanent advisory committee to assist the Minister in the use of his powers. This recommendation was rejected and it is presumably to be left to the food department of the Ministry of Health to advise on the legislation required. Mention is made of informal conferences with manufacturers and other interests, but many close students of affairs will find this a poor substitute for an advisory committee, representative of all interests, which would not only advise but, if the need arose, stimulate to activity the government department. The need for some outside assistance is admitted in the report, where the suggestion is made that in case of wide divergence of view between the parties interested or special difficulty in arriving at a decision, the matter should be referred to a committee of three independent persons who would hear evidence and report to the Minister.

Some secondary points of considerable importance are discussed in the report. Foods specially offered for infants and invalids should bear on the label of the package containing them a declaration of their contents. Misleading food advertisements and food labels are dealt with by the suggestion that for purposes of evidence as to the nature, quality, and substance demanded of a food specific claims made in advertisements should be deemed to be part of the package label. Many purchasers buy not on a label but on the assertions in the advertisement. The immense development of pre-packed articles demands a change in the law, and the report recommends that the primary responsibility under the law should be transferred to the packer and that the retailer (where he is not the packer) should be absolved from proceedings if he can show that he sold the article in the same condition as he received it and took adequate steps to protect it during storage. Such an alteration of law, with its consequent changes as to sampling, will save much waste of time to sampling authorities and irritation to retailers.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, May 29th, under the presidency of Sir Norman Walker.

WE regret to announce the death of Dr. David Ogilvy, medical superintendent of the London County Council Mental Hospital at Epsom, which occurred on May 13th, at Longrove House, Epsom.

THE series of articles on Prognosis contributed by invitation will be resumed early in June, when publication of the concluding lectures on the Preventive Aspects of Medicine at King's College has been completed.

SUSSEX PROVIDENT SCHEME.—The sum of £11,449 has been paid through this scheme to hospitals and coöperating bodies for services rendered to subscribers during the half-year ended on March 31st. The Royal Sussex County Hospital received £3833; the Royal Alexandra Hospital for Sick Children, £1361; and the New Sussex Hospital for Women and Children, £1161. The two Sussex county councils, two corporations, four education authorities, and four nursing associations, were also included in the allocation.

THE PREVENTIVE ASPECTS OF MEDICINE

A Series of Lectures in progress at King's College Hospital Medical School

XXII.—THE PREVENTION OF ACCIDENTS

THE constellation of causes producing those unexpected events called accidents is made up of two factors, material and personal, which vary greatly in their relative importance. At one extreme is an accident arising from a novel and therefore unforeseen defect in material; at the other is a mishap brought about by the eccentric behaviour of an individual, in circumstances where, except for that eccentricity, no accident could arise. As an example of the latter I was once shown a machine so efficiently guarded that I was challenged to introduce a finger into the working parts, yet was assured that a lad working at the machine had, by some extraordinary gymnastics, managed to get his hand seriously injured.

The material factors responsible for accidents have been officially recognised since the Factory Act of 1844, which was the starting point of statutory provisions for those mechanical protections of the worker which have now become so extensive that they form a subject of study by themselves. In addition there are numberless customs established by experience, such as, in our own little world, the counting of swabs at the close of an operation or holding a bottle by the neck when putting in the cork, the violation of which carries a risk. As a recent development, the "Safety First" Association seeks to inculcate, on a voluntary basis, the importance of behaviour in accident production.

The systematic study of accidents in their incidence and personal "causes" was begun towards the end of the late war under the direction of what is now the Industrial Health Research Board. This work was not concerned so much with mechanical safeguards—that aspect of the subject offered little new—as with the effect of occupational conditions upon the worker. Further, the important fact that a minority of workers are responsible for more than their proper share of accidents, if not actually a discovery of the Board's investigators, was first established by them upon a statistical basis. The phrase "accident proneness," now in world-wide use, was originally coined by Mr. Eric Farmer, whose investigations I shall describe later.

Occupational conditions affecting accident incidence were studied in 1917–18 by Osborne and Vernon. In their report they quote American figures showing a notable increase of accidents with increase of output, so disproportionate that a 5 per cent. increase in output caused a 20 per cent. increase in accidents; an excessive turnover in personnel, with an excessive number of inexperienced men as a consequence, threw doubt upon the validity of the figures which, at first sight, indicated a close relation between fatigue and accidents. It was shown, however, in our munition factories, that accident incidence in women bore a definite relation to the extent of working hours, and at the time this was ascribed to the influence of fatigue. Since then we have come to be cautious in the use of the conception of fatigue; fatigue in industry is not the simple phenomenon seen in a nerve-muscle preparation, but factors such as boredom, incentive to work, and opportunities for divided attention play a part in manifestations for which the easy diagnosis of fatigue is misleading.

We can, however, accept without further discussion that accidents are influenced by hours of work, speed of output, temperature, lighting, inexperience, and youth of the worker. These conditions affect the behaviour of the worker; their results may be specific to the individual but their existence is general.

A new approach to the problem was opened up by Greenwood and Woods, who published in 1919 an important statistical examination of the individual distribution of accidents.

The fact is easily established that when people are engaged upon a specific task and exposed to risk of accidents, especially so trivial as to allow the victim to continue at work, it is observed that some have no accidents, some have one, some two, and some more than two.

If these accidents were accidents in the strict sense: if each stood alone and the occurrence of one accident to an individual had no relation to his likelihood of having another, then the distribution described above would conform to the type of a pure chance distribution.

If, however, the occurrence of one accident altered the chance of the victim incurring another, just as one attack of a disease may lead to immunity or to increased sensitivity, the type of chance distribution would not fit. The distribution would be biased.

A third possibility is that the workers differed from the beginning, that some of them were more liable to suffer mishaps than the rest of the group. Then the distribution would depend upon unequal liabilities.

It was readily shown that those people who had an accident in one period had more accidents in a second period than any chance distribution would give; those who were immune to accidents in the first period tended to be immune in the second. That is, the incidence of *first* accidents was not a chance distribution. Varying individual susceptibility to accidents is therefore an extremely important factor in determining the distribution. Further statistical work by Miss Newbold in 1926 confirmed this finding, the consistence of individual tendency to accident being shown by the association found between (1) accidents in two different periods, (2) accidents of one type and accidents of other types, and (3) accidents in the factory and accidents at home.

Accident Proneness

Up to this point the only means of recognising liability to accident is the occurrence of repeated accidents, but Farmer and Chambers now set out to discover some method of examination that might reveal it by other means. In this they have succeeded, and "accident proneness" as used by them indicates the possession of those qualities which have been found by independent research to lead to an undue number of accidents.

In their investigations they used a battery of psychological tests and found that a group made up of the dotting test, reaction-time test, and pursuit-meter test (called æstheto-kinetic tests) yielded significant correlation coefficients between the scores and the accident rates. Ocular muscle-balance tests gave an interesting result. Hyperphoria was definitely related to an increased accident rate, whilst the percentage difference in accident rate between those with and those without eso- or exophoria was inconsistent: in one large group persons with these defects actually had a lower accident rate than those free from them. Intelligence tests produced results that had no relation to accident incidence, but tremor, though occurring in only a few cases, was, as might be expected, correlated therewith.

This brief account gives a poor impression of the complicated work involved, and omits many points of interest. Heterophoria, for example, was correlated with accidents; so were the æstheto-kinetic tests;

some fish and frogs about — 3° C.; for macaques + 14° C. and for man + 24° C. It should be emphasised that all these temperatures refer to actual tissues and not to the surrounding medium; the length of time for which they can be withstood is not given in all cases, but a sufficiently clear idea is obtained for comparative purposes. Vlès himself writes :—

> "It seems that the temperature of coagulation of the protoplasmic colloids determines the irreversible thermal limit; but in reality disturbances are manifested long before the temperature of gross coagulation of the isolated proteins is reached. A whole series of physico-chemical mechanisms is affected by a rise of temperature . . . electrolytic dissociation . . . viscosity . . . colloid equilibrium and permeability . . . "

Liquefaction of fats and lipoids may occur, mitochondria may disappear, and marked change of reaction may supervene as a result of interference with the tension of carbon dioxide and its equilibrium with bicarbonate.

In addition to this there is the probability of establishing a vicious circle; increase of temperature stimulates metabolism, and this in itself produces internal heat. Although poikilothermic animals may have a rudimentary temperature control, directed in the main to combating low temperatures, it is unlikely that this is vested in the individual cells or tissues; as in warm-blooded animals it is probably a reflex phenomenon in which the animal as a whole is concerned. In other words, the passively heated tissue is not only defenceless, but even assists in its own destruction.

FOOD STANDARDS

THE British housewife, although she may not have much knowledge of the principles of nutrition, makes her purchases with considerable skill, having regard to the dietary, tastes, and customs of different parts of the country. THE PREVENTIVE ASPECTS OF MEDICINE

A Series of Lectures in progress at King's College Hospital Medical School

XXII.—THE PREVENTION OF ACCIDENTS

THE constellation of causes producing those unexpected events called accidents is made up of two factors, material and personal, which vary greatly in their relative importance. At one extreme is an accident arising from a novel and therefore unforeseen defect in material; at the other is a mishap brought about by the eccentric behaviour of an individual, in circumstances where, except for that eccentricity, no accident could arise. As an example of the latter I was once shown a machine so efficiently guarded that I was challenged to introduce a finger into the working parts, yet was assured that a lad working at the machine had, by some extraordinary gymnastics, managed to get his hand seriously injured.

The material factors responsible for accidents have been officially recognised since the Factory Act of 1844, which was the starting point of statutory provisions for those mechanical protections of the worker which have now become so extensive that they form a subject of study by themselves. In addition there are numberless customs established by experience, such as, in our own little world, the counting of swabs at the close of an operation or holding a bottle by the neck when putting in the cork, the violation of which carries a risk. As a recent development, the "Safety First" Association seeks to inculcate, on a voluntary basis, the importance of behaviour in accident production.

The systematic study of accidents in their incidence and personal "causes" was begun towards the end of the late war under the direction of what is now the Industrial Health Research Board. This work was not concerned so much with mechanical safeguards—that aspect of the subject offered little new—as with the effect of occupational conditions upon the worker. Further, the important fact that a minority of workers are responsible for more than their proper share of accidents, if not actually a discovery of the Board's investigators, was first established by them upon a statistical basis. The phrase "accident proneness," now in world-wide use, was originally coined by Mr. Eric Farmer, whose investigations I shall describe later.

Occupational conditions affecting accident incidence were studied in 1917–18 by Osborne and Vernon. In their report they quote American figures showing a notable increase of accidents with increase of output, so disproportionate that a 5 per cent. increase in output caused a 20 per cent. increase in accidents; an excessive turnover in personnel, with an excessive number of inexperienced men as a consequence, threw doubt upon the validity of the figures which, at first sight, indicated a close relation between fatigue and accidents. It was shown, however, in our munition factories, that accident incidence in women bore a definite relation to the extent of working hours, and at the time this was ascribed to the influence of fatigue. Since then we have come to be cautious in the use of the conception of fatigue; fatigue in industry is not the simple phenomenon seen in a nerve-muscle preparation, but factors such as boredom, incentive to work, and opportunities for divided attention play a part in manifestations for which the easy diagnosis of fatigue is misleading.

We can, however, accept without further discussion that accidents are influenced by hours of work, speed of output, temperature, lighting, inexperience, and youth of the worker. These conditions affect the behaviour of the worker; their results may be specific to the individual but their existence is general.

A new approach to the problem was opened up by Greenwood and Woods, who published in 1919 an important statistical examination of the individual distribution of accidents.

> The fact is easily established that when people are engaged upon a specific task and exposed to risk of accidents, especially so trivial as to allow the victim to continue at work, it is observed that some have no accidents, some have one, some two, and some more than two.
>
> If these accidents were accidents in the strict sense: if each stood alone and the occurrence of one accident to an individual had no relation to his likelihood of having another, then the distribution described above would conform to the type of a pure chance distribution.
>
> If, however, the occurrence of one accident altered the chance of the victim incurring another, just as one attack of a disease may lead to immunity or to increased sensitivity, the type of chance distribution would not fit. The distribution would be biased.
>
> A third possibility is that the workers differed from the beginning, that some of them were more liable to suffer mishaps than the rest of the group. Then the distribution would depend upon unequal liabilities.

It was readily shown that those people who had an accident in one period had more accidents in a second period than any chance distribution would give; those who were immune to accidents in the first period tended to be immune in the second. That is, the incidence of *first* accidents was not a chance distribution. Varying individual susceptibility to accidents is therefore an extremely important factor in determining the distribution. Further statistical work by Miss Newbold in 1926 confirmed this finding, the consistence of individual tendency to accident being shown by the association found between (1) accidents in two different periods, (2) accidents of one type and accidents of other types, and (3) accidents in the factory and accidents at home.

Accident Proneness

Up to this point the only means of recognising liability to accident is the occurrence of repeated accidents, but Farmer and Chambers now set out to discover some method of examination that might reveal it by other means. In this they have succeeded, and "accident proneness" as used by them indicates the possession of those qualities which have been found by independent research to lead to an undue number of accidents.

> In their investigations they used a battery of psychological tests and found that a group made up of the dotting test, reaction-time test, and pursuit-meter test (called æstheto-kinetic tests) yielded significant correlation coefficients between the scores and the accident rates. Ocular muscle-balance tests gave an interesting result. Hyperphoria was definitely related to an increased accident rate, whilst the percentage difference in accident rate between those with and those without eso- or exophoria was inconsistent; in one large group persons with these defects actually had a lower accident rate than those free from them. Intelligence tests produced results that had no relation to accident incidence, but tremor, though occurring in only a few cases, was, as might be expected, correlated therewith.

This brief account gives a poor impression of the complicated work involved, and omits many points of interest. Heterophoria, for example, was correlated with accidents; so were the æstheto-kinetic tests;

but heterophoria and these tests did not correlate between themselves. That is to say, they probably were measures of different qualities unrelated in themselves yet both concerned in the production of accidents. An important by-product of the investigation was the discovery that the æstheto-kinetic tests and the intelligence tests correlated positively with industrial proficiency, though they did not correlate with each other. Also none of the tests correlated with sickness incidence, although that correlated with accidents and industrial proficiency.

Detection of Psycho-Neurotic Symptoms

These tests are all objective and presumably independent of any personal bias of the observer. But the æstheto-kinetic group depend upon the behaviour of the subject; so do accidents, and we can express the results by saying that people who behave in a particular way at the tests will tend to behave at work in such a way as to produce accidents. This consideration provides a convenient link with a method of investigation which leads by another road to possibly similar results. Beginning with a research into telegraphists' cramp—which, according to modern views, is not to be regarded as a disorder of muscle or nerve but of behaviour, like a stammer—I have been led on to systematise a method of interviewing designed to elicit the presence of psychoneurotic symptoms among presumably healthy people. Everyone dealing with "nervous" patients develops his own method of eliciting what he regards as diagnostic information; questionnaires for the same end are to be found in the literature and they apparently find favour in the United States. As guides to a beginner in interviewing such questionnaires are useful, but when handed to the subject for written answers they seem to me quite inadequate. I recollect being given, when a student, a book of instruction in case-taking which was practically a questionnaire for my guidance; to hand the book to the patient and invite his answers did not enter my mind or that of my teachers. A knowledge of disease and symptomatology was necessary in order to follow up the clues given by the patient, and in the same way an interviewer seeking for "nervous" symptoms or temperamental qualities must know what to look for and how to look for it.

I have now used and taught the method of personal interview sufficiently to be sure that the results are consistent and reliable, whether the work is done by myself or a trained assistant. As a check upon my findings, however, I used the McDougall-Schuster dotting machine, which was also included by Farmer and Chambers in their tests. I classified my interview results numerically, and statistical methods showed that a high incidence of nervous difficulties correlated with a poor dotting record.[1]

About 20 per cent. of the working population studied by me suffered from nervous symptoms which, in my judgment, interfered with happiness and efficiency; they also did, on the whole, a bad dotting test. Farmer and Chambers found that about 20 per cent. of their working population had a high accident incidence and did, on the whole, a bad dotting test. It is not practicable to stage another investigation to test the identity of their 20 per cent. and mine, but if we assume their identity—or a high correlation between them—then we have gone a step farther and may hope sometimes to find an answer to the question why a particular individual is prone to accidents. Farmer and Chambers point out that "the correlation coefficients between the tests and accident rates were for the most part small, this suggesting that accident proneness is dependent upon many dominant factors and not on a single predominant one, and affording no evidence that the tests measure the most important of these. This can only be determined by further experiment." The practical value of the tests is suggested by the fact that in the æstheto-kinetic group the accident rate of the worst 25 per cent. was about two and a half times as great as that of the remaining 75 per cent. Their applicability in eliminating the accident-prone is obvious, and would, I think, be increased by the addition of the personal interview.

It is to be noted that the tests themselves bore no relation to the occupation of the subjects, who were apprentices in the workshops of Naval and Royal Air Force establishments. Any large group of workers whose conditions were sufficiently uniform to provide statistically reliable material would have served equally well.

The investigators refrained, in the case of æstheto-kinetic tests, from making any claims as to what qualities they were testing. The McDougall-Schuster dotting machine was designed as a test of sustained voluntary attention but is cross-cut by other factors. In the hands of McDougall and May Smith it proved useful as an indicator of the results of loss of sleep or the administration of certain drugs, but only when the normal test-result of the subject was established. May Smith and myself found that its results correlated with the presence and degree of psychoneurotic symptoms. But *what* it measures we do not venture to say; nor do Farmer and Chambers.

Tests for Motor Drivers

Quite a different principle is claimed for tests now coming into use for the purpose of eliminating unsuitable men from those proposed for training as motor drivers. The National Institute of Industrial Psychology has devised a series of tests for the purpose of directly measuring certain qualities regarded as essential to safe and efficient motor driving. Reaction time, resistance to distraction, vigilance, judgment of speed, judgment of spatial relationships, confidence, road behaviour, vision, these and other qualities are given separate markings, the final judgment resting upon the whole profile. This method works, and those who rank badly upon the tests are shown by their records to be liable to an excess of accidents. Yet while some of the tests certainly measure a definite quality—reaction time and vision, for example—it is possible that some are not so specific and, correlating in their results with accident proneness, approach to the æstheto-kinetic tests in measuring an unknown something.

Good results are claimed for work along similar lines in Paris and some American cities. In the latter, however, another mode of attack is introduced. The accident-prone driver is interviewed, and W. V. Bingham has described the extraordinarily mixed bag of results that were obtained. A single bad habit in driving, susceptibility to a small dose of alcohol, wilful road-hogging, loss of sleep, family worries, reckless operation calling for discipline, lack of correct instruction, were found as causes, whilst a few drivers seem to have been born into the accident-prone class. For the tramways and buses of Paris it is claimed that psycho-physiological selection before training has reduced the percentage of unsuitable trainees from 20 to 3·4. (Note here the appearance again of that 20 per cent. discovered by Farmer and Chambers and by myself.)

---

[1] Since the possibility arises of finding clinical value in this test as a diagnostic weapon, it must be pointed out that a statistical correlation between factors does not imply that one of them can be used in an individual case to infer the presence of the other. Subjects with hysterical or anxiety symptoms tend to do a bad dotting; so do the accident-prone; but not every subject belonging to one of those groups makes a bad score, nor does every subject with a bad score belong to one of those groups. Only one kind of dotting is found almost invariably to indicate a particular temperament; an exceptionally good score accompanies that obsessional make-up commonly described as "nervy" or "highly-strung," and this even in cases where disabling symptoms are present, so long as they are not associated with pathological anxiety. On a few occasions a very good record has put me on the track of obsessional symptoms that I might otherwise have missed, but that is the only claim I make for any clinical value in the tests beyond a confirmation of opinions already formed.

Some Individual Examples

Leaving these general considerations let us glance at isolated examples that may reveal specific factors.

A building operation necessitated the engagement of a large staff of labourers, and among them were many skilled workers—engineers, for example—who through economic conditions were compelled to accept this low-grade task. The medical man in charge noted an excess of accidents in this group and, in discussing it with me, ascribed it to the fact that the job was temporary but that disablement, with its accompanying compensation, might be more lasting. Please accept my assurance that my colleague, who was not ignorant of psychopathology, did not ascribe this to a witting attempt at fraud, but believed that the total of conditions could so affect the men that unconscious motivation came into play. Cases to be described later give, I think, proved examples of unconscious motivation.

Another case is cited by an American writer where dismissals on a large scale took place, falling by preference upon recently engaged workers. The elimination of inexperienced men was expected to reduce accidents, but the number showed a considerable increase. The explanation offered was that the remaining workers were in such dread of dismissal that the worry affected their work and led to accidents.

In both these cases I would point out that the explanations, though plausible, were quite speculative and could perhaps have been tested by the method of the interview.

Therapeutic methods that involve detailed histories or the application of psycho-analytical principles may lead to the elucidation of accidents that happened in the past. One war sufferer wrote for me his autobiography, which involved a hard childhood and the growth of pathological fears. I will give in his own words the description of an accident brought about by these fears :—

> Now I have managed to learn to work the signal box, and I get shifted to a signal box at ...... ; my first night on is a Friday night, and the box must be washed out; the man I am relieving stays a little while whilst I take off a few trains, then he leaves me. Whenever he goes there is a fear attached to me, yet why it should be so I can't tell, so I starts to wash the floor to help take away this fear ; whilst doing so there is a goods train taking on full wagons and leaving empties ; I have two trains belled on to me. I take them on, I go on with the floor washing, then I hears three whistles as if for me to close the points, the next thing I hear is a crash and I see the guard running down to the box. He tells me I have fouled both main lines, and there I am, with two passenger trains taken on. I run to the phone and tells both boxes to stop both trains, lines are fouled, after that I am useless, fit for nothing, another man is put in the box and the stationmaster takes me to his house and trys to soothe me down. I am courtmartialled over this and has to appear before all the directors, but I was favoured to have sitting on the court, district superintendent . . . . who came only six miles from my native home. I mind the last question I was asked, have I ever been seriously hurt about the head any time. I told him about my brother letting me fall 40 feet and had been carried home as dead. I don't remember any of this incident of my life. However, I was reduced to a carriage cleaner only, for things might have been worse for me.

Since we can hope to prevent accidents only by understanding their causes we may note the inadequacy of cross-examining a man as at a court-martial. I suggest that we are missing important elements in causation by not systematically making a psychological examination of men whose unexpected reactions have brought about an accident. I think they would be in a frame of mind ready to give every help to a trained interviewer, though assurances might be necessary that confidence would be respected.

A shell-shocked soldier gave a history of having been knocked down, years before, by a wagon on a dark road and receiving a fracture of the skull. Bony deformity in the occipital region marked the site of an old compound fracture ; he claimed to remember nothing of the accident or of the preceding 24 hours, and the case seemed quite ordinary. Like many shell-shock subjects, he passed readily into a hypnoidal state in which he recapitulated suppressed episodes, and I took advantage of this to attempt the recall of the accident, in which I succeeded. He had been wandering about the country out of work, depressed, and hopeless ; leaving a village where he had failed to get assistance, he met a wagon as he turned a corner and fell under the wheel. He was not knocked down at all.

Another war patient described how he once found his bicycle getting out of control down-hill ; instead of trying to control it he became agitated by the impulse to pedal harder and force an accident. In this he succeeded and did himself some injury ; later, in the course of treatment, he recalled being initiated into masturbation whilst held on a bicycle ; he at once linked this up with the accident, relating that both to self-punishment and the masturbatory impulse.

A gentlewoman under analytical treatment told of an impulse to pick up a poker just withdrawn from the fire but no longer red hot ; she did it, and the resulting burns were treated sympathetically as acquired in ignorance of the state of the poker. She worked out the unconscious motivations of the impulse, which turned out to be very complicated.

Obsessional Impulses and Road Accidents

Cases are frequent in which an unconscious motivation seems obvious, but only when the patient reveals it can the evidence be convincing. Jung once wrote, concerning the unconscious :—

> "One of the most frequent forms of danger is the instigation to accidents. Accidents of every sort, in greater number than the public would ever guess, are of psychological origin. Ranging from insignificant mishaps like stumbling, bumping oneself, burning the fingers, &c., to automobile accidents and catastrophes in the mountains, instances may be found of psychological causation, the accident being sometimes prepared weeks or even months ahead."

Psychoneurotic inhibitions or impulses easily predispose to accidents, especially in motor driving. I know a colleague who has an impulse to charge at an oncoming vehicle, and takes it so seriously that he has given up driving. The driver of a commercial vehicle whom I saw at a clinic admitted the same symptom, sometimes so strong that at the sight of a doctor's plate he felt that he would stop driving and rush in with an appeal for help ; I trust that he followed my advice to seek another occupation, for one's ethical position in such a situation is difficult. Fears of something on the right or the left, or coming from behind, are common symptoms that can influence driving though they are not specific to it. I had a patient who, among a wealth of symptoms, owned to one that made it impossible to drive behind another car where he could not see the road ahead of it ; he was impelled to draw out and try to pass.

All this discussion has an obvious bearing upon that road slaughter which has become so terrifying. Lord Ponsonby, speaking on the wireless recently, said that as a pedestrian he resented having to throw himself into the ditch by a country road when a driver came along at 60 or 70 miles an hour. But, like many of us, he failed to ask *why* that driver comes along at such a pace. We may select drivers, we may insist upon proper instruction, may stress good manners on the road, educate pedestrians, teach "safety first" to school-children, but we cannot escape the conclusion that, without high speed, motor-car accidents would be much fewer, even though it may be possible to demonstrate in every accident that something other than speed was its decisive cause. An obsessional impulse to speed is found in some people. One pedal cyclist described this impulse to me, and said: "I know I shall get it in the neck some day; but I can't help it, I *must* rush." He also suffered from telegraphists' and writers' cramp, in the causation of which the impulse to rush played a part.

Used with a strict meaning the word *obsession* indicates an urge to think, feel, or do something that is recognised by the subject as irrational and may be effectively resisted. Used in that sense the word is not applicable to the impulse to speed that exists in many drivers, which is neither recognised as irrational nor effectively resisted. To speak still in the language of psychopathology, it is defended by rationalisations, by pseudo-reasons and justifications which are evolved to account for something that arises from quite different and perhaps unknown motivations.

Often, indeed, it is treated as calling for no justification, and a correspondent in the *Times* of May 7th naïvely provides an example. Under the heading of "Sneezing at the Wheel," he remarks that "the danger resides in the fact that it is virtually impossible to sneeze with the eyes open, and at 60 or 70 miles an hour that split second of blindness suffices to precipitate disaster. My own practice, when I detect the premonitory symptoms, is to slow down instantly. . . . . I am quite sure in my own mind that a sudden sneeze is the true explanation of many otherwise unaccountable motoring accidents."

The public acceptance, twice within seven days, of 60 to 70 miles an hour as a speed calling for no question, gives food for thought to one whose experience of road traffic goes back to the use of the old tall bicycle. How has it come about that we are reconciled to the speed of an express train on our high roads? If one questions people, especially drivers, about the attraction that high speed undoubtedly possesses, the answers indicate that fundamental instinctive tendencies there find satisfaction. Sense of power, aggressiveness, risk, or in more general terms "the thrill of it," are part of the attraction, and whoever has heard an enthusiastic motor-cyclist describe the thrill of travelling at 70 miles per hour may ask whether it is not time that the satisfaction of this particular instinctive urge should be frowned upon not merely because of its material but also of its psychological danger. To provide a reasonable outlet for instinctive tendencies is one thing, to cultivate their excessive development is another. The change from the days of the tall bicycle has come about by the gradual cultivation of a tendency that grows by being fed, and only the general distribution of the instinctive tendency has allowed us to become reconciled to a total of killed and maimed that a few years ago would have appeared as fantastic. Every mechanical improvement, whether in roads or machinery, is brought into the service of increase of speed, and unless we can in some way retrace our steps the casualty totals will increase. If this view is correct, it follows that palliatives that do not take into account the checking of the instinctive tendency may themselves make matters worse. Instruction may be enforced upon all would-be drivers; but the personality of the instructor may be such as to infect the learner. The improvement of roads is already recognised as leading to increased accidents, and the objection of cyclists to carrying rear lights has behind it the not unreasonable belief that another check upon speed—though a dangerous one—will be removed.

CONCLUSION

Preventable accidents constitute a problem of human behaviour, and, where that is concerned, facile explanations and obvious measures of control are apt to disappoint. If I have not simplified the subject it is the fault of the subject and our misfortune; but it is clear that in the recent work here described we are feeling our way to an understanding of the behaviour problems underlying accidents and thereby furthering their prevention.

Squadron Leaders to be Wing-Comdrs.: R. A. G. Elliott, J. M. A. Costello, P. H. Young, P. T. Rutherford, T. Montgomery, and H. L. Burton.

Flight Lt. (Hon. Squadron Leader) W. S. Stalker *relinquishes his temporary commission on completion* of service.

SPECIAL ARTICLES

MORTALITY OF BRITISH MERCHANT SEAMEN

By Fleet-Surgeon W. E. Home, O.B.E.

What is the death-rate of British merchant seamen, and is it higher or lower than that of the average worker in British industry? Important questions for answering which there is no accurate information available, yet a discussion of knowledge now obtained from the figures for 1929–30 may do something to advance the study of the hygiene of seamen and to lessen their deaths in future.

In the first place, what is the general death-rate of British industry? The basic figures for England and Wales are got from the Registrar-General's Decennial Supplement to his report on the Census, the latest being "Part II., Occupational Mortality, 1921," issued in 1927 in relation to the Census of 1921, the basic table being that on p. 2, dealing with "All Occupied and Retired Civilian Males," ages 16 and over. Here are assembled all the 509,204 deaths that had been registered from this group during the three years 1921–23, and these, correlated with 35,358,036—three times the numbers in the group as enumerated at the Census—yield a death-rate of 14·32, the average age of the group being about 38.

For some years before this report appeared, in fact since 1924, the Royal Sanitary Institute had been explaining to the Board of Trade that it was important to obtain a death-rate for the employed seamen in the merchant service analogous to the death-rates published annually for the Army and Navy. Labour members of Parliament had been pressing this point of view, and the Board of Trade set up a committee to consider the matter. The committee reported in 1926 that a death-rate for only the employed men of the merchant service (of whom alone the Board has cognisance) would be of no value for comparison with death-rates propounded for other industries, as in these other trades the deaths of men occupied and retired are always considered together. The numbers indeed of British merchant seamen employed on ships were roughly known to the Board as were also their deaths, but as regards men who had left the sea, their deaths were reported, not to the Board, but to local registrars; nor was their total number known. The committee asked the Registrar-General to do what he could in his then forthcoming report to elucidate this problem. Accordingly in 1927 he produced, on p. 128 of his report alluded to above, a statement of all the British seamen, ages 20 to 64, that had come to his notice through examining the 1921 Census reports for the United Kingdom as well as the Board of Trade's Census of Seamen for the same year; they were in all 199,306, their average age being about 33. With these figures he printed a summary of their deaths at sea reported to the Board of Trade in 1921–23, and of their deaths ashore (unemployed and retired) extracted from the returns of local registrars. He found in all 7924 deaths, corresponding to a death-rate of 13·27, a statistic incomplete indeed, but far more nearly complete than anything we had had before.

To get a comparable figure from industry ashore it was necessary to extract from the basic table the number of deaths and of persons noted between ages 20 and 65; the deaths were 266,384, the years of life, 29,114,580, yielding a death-rate of 9·15, the average age being again about 38. Within their industry seamen are much younger than men in other industries, and as the young have a lower death-rate, if seamen had died according to the rates for men of their ages in the basic table, their standard death-rate would have been 7·17; so their actual rate, 13·27, was nearly double the standard. Seafaring thus seems an unhealthy occupation. In fact, the Registrar-General, without even making allowance for their younger ages, thought their mortality 75 per cent. worse than the average (see Diagram 1). Thus we have these death-rates for men between 20 and 65:—

	Average age.	Death-rate.
All occupied and retired civilian males ..	38	9·15
All seamen, standard rate	33	7·17
All seamen, actual figures	33	13·27

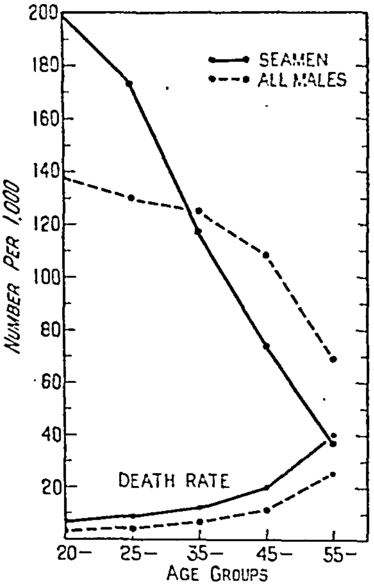

FIG. 1.—The two upper curves show the age-distribution per 1000 of seamen aged 20–64 years and the age-distribution of all occupied males of the same ages in England and Wales. The two lower curves show the death-rates per 1000 of seamen and occupied males. (The chart is based on figures published in the Registrar-General's Decennial Supplement, England and Wales, 1921; Part II., Occupational Mortality, 1927).

It was shortly recognised that the figures of the Registrar-General were out of touch with reality, for on one side the class of British merchant seamen was too little defined, and on the other not all deaths reported were relevant, nor were all the relevant deaths brought to account. So in 1929 the Board of Trade initiated another examination of the records of seamen and their deaths in the 12 months from Oct. 1st, 1929, to Sept. 30th, 1930, in the course whereof the reports and certificates of deaths, whether sent to the Board of Trade or to the local registrars, were carefully scrutinised, and several were excluded from computation as not applying to men who had served in the British mercantile marine. Ultimately it was decided that there had been in the particular year under scrutiny among the 127,518 seamen actively employed on ships and enumerated in the 1930 Census of Seamen, 642 deaths, and in addition, among seamen unemployed or retired, 2524 deaths ashore in the United Kingdom. The total number of these seamen unemployed or retired was really unknown at that time, but there will be an estimate in the final report of the Registrar-General on the Census of 1931. Yet the number even then will be uncertain, partly because seamen when retired take up other employments to which they now assign themselves in the Census, and partly because seamen, during the years they are going to sea, are constantly flitting between the employed and the unemployed (or retired) categories and back again, far oftener than other workmen, whose passage from employment to retirement is usually definitive, and rarely reversible; seamen, on the other hand, are always becoming unemployed at the end of cruises, though they would be surprised, perhaps indignant, if they were then supposed to be retired. See what may happen at home: a seamen leaves a ship on a Tuesday, that night he is unemployed and so remains till Friday, when he "signs on" on another ship. Suppose that that Friday evening he is run over by a car, and (*a*) is taken to hospital, where he dies that night. His death is now reported to the Board of Trade as that of a seaman on articles. Next suppose he was (*b*) not at once killed; his place on his ship must be filled, so he is discharged and replaced, and when he dies in a week, his death is now reported, not to the Board of Trade, but to the local registrar as that of a retired seaman; this is what would have happened (*c*) if his accident had happened on the Thursday when he really was unemployed. There is no list or enumeration of retired or unemployed seamen at any point in their career, so a death-rate other than approximate for them is unattainable; their number is unknown, and it is something of an accident if their deaths are recorded as those of British seamen, and if the deaths so recorded are truly those of seamen in the merchant marine.

Nevertheless this last investigation by the Board of Trade, with its results published in the Blue Book, "Statistics relating to the Mortality in the Mercantile Marine" of 1932, has told us much that is new and qualitatively important. The only attempt at vital statistics for seamen are those published by the Board of Trade. In a recent publication of the International Labour Office on the diseases of seamen, no other country seemed able to give any figures about prevalence of a disease nearer than the proportion of its deaths to total deaths. The Blue Book referred to above shows on Table XVII. (p. 51) that for 502 (20 per cent.) of the 2524 deaths ashore, unemployed and retired, in the special year, their time since leaving the sea was unknown, but that of the other 2022 deaths, 1043, more than half, occurred in the first five years after leaving the sea, 294 in the second five years, and only 685 in all the years thereafter. Again, of the 1043 who died in the first five years, 625, more than half, died in the first year, 155 in the second, 98 in the third, 86 in the fourth, and 79 in the fifth. And again, of the 625 who died in the year after leaving the sea, 298, nearly a half, died in the first three months, 151 in the second, 90 in the third, and 75 in the fourth three months after leaving the sea. So deaths are far more numerous just after the men leave the sea, and decrease steadily per unit of time for the next ten years. This seems to suggest that many men become unemployed or retired because they are ill, in fact dying; the merchant service, unlike the Navy, recognises no invaliding, the men must arrange that for themselves.

Nothing is said in this Blue Book about the diseases which cause such early mortality among the retired seamen, for the inquiry, like others at that time, was hampered by the need for economy. But that we should know what these diseases were was obviously a matter of great importance, and the President of the Board of Trade, approached by Sir Francis Fremantle, M.P., a former president of the epidemiological section of the Royal Society of Medicine, of which I have been a member since 1887, kindly allowed me to examine the certificates of the "deaths ashore in the United Kingdom" that had occurred during the special year, and within 12 months of leaving the sea. Some interesting figures emerged, published in THE LANCET (August 19th, 1933, with a preliminary note on p. 371). Here one need only say that while in 1929–30—and we may reasonably suppose, somewhat similarly in other years—there occurred 642 deaths among the 127,518 employed seamen, there came to notice nearly as many, 622, among what one would expect to be a much smaller population, the unemployed and just (within 12 months) retired. Among the employed the deaths by disease were 288, but there were 556, nearly twice as many, among the unemployed and just retired. Again, and more striking still, if we take 288 as the number of deaths by disease of the year among the employed, it is not extravagant to suppose these deaths equally distributed throughout the year, that is 72 per quarter; but we are then astonished to find that the deaths by disease in the first three months after leaving the sea were 267, nearly as many as in a whole year among the employed, four times as many as in three months among the employed, whose ranks they have just left, without having had time yet, one would think, to have picked up new illnesses (Diagram 2).

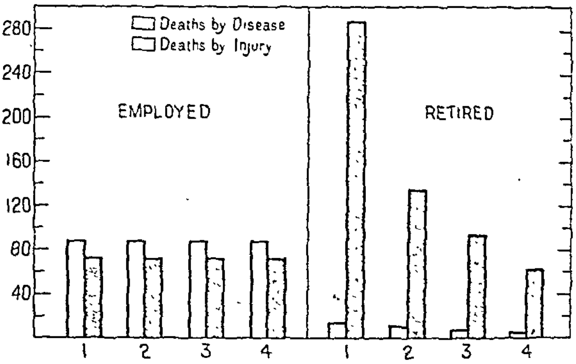

FIG. 2.—Deaths of British merchant seamen by disease and accident, during employment and after retirement. The number of deaths aboard ship (288 by disease and 354 by violence) during one year has been divided into four quarters so as to be comparable with the number of deaths in the first, second, third, and fourth 3 months after retirement, during the same year.

The figures about deaths from pneumonia and tubercle (all) were arresting. Of the 127,518 employed seamen there died during the year 31 of pneumonia and 24 of tubercle; as we may say, per quarter, 8 of pneumonia and 6 of tubercle, but of the "unemployed or just retired" there died of pneumonia, in consecutive periods of three months after leaving the sea, 44, 12, 4, and 3, in all 63, and of tubercle (all) 29, 30, 34, 17, in all 110. If deaths occur like that in other than the special year (and why should they not?), there will fall to be added to the deaths in the Annual Return of deaths of employed seamen, from pneumonia twice as many, and from tubercle, four times as many, before we are in a position to realise how many deaths from these diseases should really be ascribed yearly to service in merchant ships, or what amount of preventable disease there is to combat in the mercantile marine.

Dr. J. Howard-Jones and others who, like myself, have long been urging the need for better sanitation on board and more cubic space for the men in the crew spaces of merchant ships, have been constantly met with the argument that the relatively few deaths from pneumonia and phthisis recorded in the annual Return of Deaths, issued by the Board of Trade, rather tended to contradict us, and to show we were exaggerating the defects of ships; but if there is at least twice as much pneumonia among British merchant seamen, and four or five times as many deaths from tubercle as, before this Blue Book came out, we believed, it may well be we were right all the time.

Another thing: is it right for shipowners to unload yearly 100 cases of tubercle on to the general public to be cared for till they die, when many of them must, without any reasonable shadow of doubt, have become infected at sea? Should they not be a charge on the industry, as are miners suffering from silicosis, under the Act of 1918?

How many similar deaths of men just retired, and dying as civilians, should be charged to the Army, Navy, or R.A.F.?

Tubercle (all), 1930

—	Total	Cases	Per 1000	Deaths	Invalids	Deaths of invalids within a year
Army ..	178,384	248	1·4	31	200	Not known
Navy ..	88,840	215	2·4	15	210	,,
R.A.F. ..	32,000	27	0·9	3	27	,,
Merchant service	127,518	—	—	24	—	110

The figures in this paper lead to no death-rate, so are obviously incomplete. Of the 2524 deaths of retired seamen in the special year, 294, or 11 per cent. of them, were due to tubercle. Among the 622 deaths, already discussed, occurring within a year of leaving the sea, 110, or 17 per cent., were due to tubercle, the chief cause for this group. The toll which tubercle takes of seamen is serious. What a pity the Board of Trade had not had a D.P.H. or medical statistician on the staff in 1900 to get out facts like those in the recent Blue Book when the Merchant Shipping Act of 1906 was on the stocks. Then, in addition to good orders about foods and cooks, we might have had others about sufficient cubic space for seamen on ships, as their risks would then have been widely known, and not only, as at that time, to medical officers of health to port sanitary authorities.

The figures here submitted are incomplete, but such as they are it has taken nine years to get so far, and as no more knowledge is expected to be obtainable in the immediate future, they are submitted for the information of future students of that rather neglected chapter of hygiene, the mortality of British merchant seamen.

POSTSCRIPT

A rough approximation to the true death-rate of employed British merchant seamen can be got for any year in which the Census of Seamen is held, though this only gives their number on one day out of the 365; for their deaths are recorded pretty accurately every year by the Board of Trade. But deaths of seamen retired, and their numbers, are nowhere stated; and a death-rate for seamen "occupied and retired" is therefore unobtainable.

Death-rates per 1000 for the Merchant Service (occupied)

Census date	1901	1911	1921	1930	1931
Total force	120,412	136,580	96,072	127,518	108,882
Death-rates from—					
Disease	5·8	4·7	4·3	3·1	3·1
Violence	8·0	10·9	4·6	2·4	2·3
All causes	13·8	15·6	8·9	5·5	5·4

The death-rate from violence in sailing ships in 1901 and 1911 was 14·3; it is not known in other years. In 1911 673 seamen were lost in the *Titanic.* In 1929–30 deaths by disease for the first time exceeded deaths from violence. Deaths by alcohol are here included with deaths from disease.

Service Death-rates in 1931

—	Merchant service.	R.A.F.	R.N.	Army.
Total force	108,882	32,448	87,075	178,384
Death-rates from—				
Disease	3·1	1·51	1·3	1·76
Violence	2·3	2·9	0·9	1·01
All causes	5·4	4·41	2·2	2·77

The only death-rates with which those of merchant seamen are at all comparable are those of the men on the active lists of the fighting services, and it must be remembered that all these have quite differing age-distributions. These are given here for 1931, the latest date for which all are available.

A CONFERENCE AT HARROGATE

UNDER the auspices of the British Health Resorts Association a conference was held on Saturday, May 12th, at Harrogate, in which the methods devised at Harrogate for dealing with diseases of the liver and of the skin were made the subjects of set discussion. The Physical Medicine Section of the Royal Society of Medicine was holding its annual general meeting at the same time, and its members coöperated in the debates.

Mr. C. D'Oyly Grange, O.B.E., F.R.C.S., president of the Harrogate Medical Society, presided at the morning session. He welcomed the Association and the section of the R.S.M. to Harrogate, and estimated that before the country went off the gold standard immense sums annually were spent in French spas for treatment that could often be obtained in British resorts. The two topics at this, the first conference of the Association to be held in Harrogate, were important ones, and he called upon Prof. Langdon Brown to open a discussion upon

The Use of Spas in Diseases of the Liver

Prof. LANGDON BROWN, Regius Professor of Physic at Cambridge, said that he would first admit that the rest and change afforded by spa treatment are beneficial when assisted by regulated diet and a scheme of life in a healthy environment, and pointed out that an efficiently organised spa would be able also to afford the benefit to be derived from subsidiary methods of treatment. An impressive body of evidence had been accumulated, he said, as to the metabolic effects of water, and what is true of metabolism in general should be especially true of that great metabolic workshop the liver. He would not try to detail the therapeutic uses that might be made of spas in diseases of the liver, but he reviewed the recent additions to medical knowledge of the functions and diseases of the organ, and asked what practical application of this learning could be made through special methods at the disposal of the spa. Ten years ago H. Maclean and O. L. V. de Wesselow had improved Straus's lævulose test of hepatic efficiency by examining the effect of the ingestion of lævulose by the blood-sugar curve; the method of direct analysis of samples of bile through the duodenal tube was now coming into use; and van den Bergh's application of Ehrlich's di-azo test for the estimation of bilirubin in the blood was revolutionising our ideas of jaundice. He agreed with A. Hurst's recent statement that these three tests are the only ones that persist as valuable; and through the same period biochemical methods had been simplified and knowledge extended by the discovery of insulin, and of the storage of certain hæmopoietic features in the liver, rendering the rewriting necessary of the stories of carbohydrate metabolism and the pathology of the anæmias. The recent discovery of the influence of choline on the fat metabolism he welcomed as promising. The main work of the liver he summarised as follows:—

"Situated on the path by which all the blood from the digestive organs enters the systemic circulation, it is not surprising to find that the liver helps to prepare all three foodstuffs for utilisation by the tissues. The bile it forms is at once an excretion and a secretion. But further, the liver is an important agent in detoxication and in maintaining the constant composition of the blood"; and he pointed out that the liver has to coöperate closely with the pancreas and the spleen in the regulation of digestion. In the assimilation of proteins he suggested that spa treatment would be of assistance, and he instanced diseases of the liver where there is extreme circulatory disturbance, as in the later stages of cirrhosis. Again, under the less severe conditions of liver accompanying the failing heart, anything which aided the true circulation of the blood through the liver would help to maintain the proper nutrition of the cells and diminish the inflow of toxic material into the circulation. Herein, he pointed out, lay the main advantage of liver packs and the similar methods applied at Harrogate. Coming next to the carbohydrates, where glycogen stores of the liver depend upon the balance between certain endocrines, opinion to-day, he said, is tending to attribute the amenable glycosuria of later life to defective storage. Biochemical advances had shown that the antitoxic power of the liver depends on the good content of glycogen, and patients receiving spa treatment, he urged, should be given the help to be found from insulin and dextrose in toxic states.

After dealing with the antitoxic and anaphylactic properties of the liver, Prof. Langdon Brown agreed with recent workers that the liver acted mainly as the storehouse of a principle formed elsewhere, while preserving the power of adding finishing touches. He discussed the value of liver or liver extract in the treatment of pernicious anæmia, and with regard to the so-called primary anæmias, he said that they could be explained in terms of failure of some stage or other in the maturation of the red corpuscles in the red marrow. But it is, he said, the principle stored in the liver which is essential to the formation of normoblasts from megaloblasts. "The other end of the story," he added, "is that the hæmatoidin supplied by the spleen from disintegrating erythrocytes is converted by the Kupffer cells of the liver into bilirubin, the former giving the indirect and the latter the direct van den Bergh reaction. The iron salts set free in this disintegration appear to be stored up in the liver ready to be used again in the formation of new corpuscles. The well-known excess of inorganic iron in the liver and spleen found in pernicious anæmia is now regarded by L. J. Witts not as evidence of hæmolysis, as was formerly thought, but of the failure of the red marrow to use this iron in the manufacture of new corpuscles. This would postulate some mechanism which normally transports iron from the liver to the red marrow." Prof. Langdon Brown acknowledged that he was rather explaining the activities of the liver in general metabolism, as a guide to further research, than making suggestions for spa treatment more than to stress the need of improving the circulation of the gland in certain liver conditions.

Turning from the internal to the external and excretory functions of the liver, Prof. Langdon Brown pointed out that the gall-bladder allowed a discontinuity in discharge of a fluid being continuously formed, while the bile, when in the bladder, lost water and received cholesterol and mucin, thus becoming concentrated and viscous until obstruction might occur. More and more, he said, he was convinced of the importance of preventing the accumulation of viscid bile in the gall-bladder, while he subscribed to the view that infection arrived at the gall-bladder as much through surrounding lymphatic channels as by ascent of the common bile-duct. He concluded by referring to the great opportunities offered at Harrogate for research in these matters into individual human reactions.

Dr. J. W. McNee spoke from the standpoint of a practical physician of the use that might be made of spas in the treatment of acute and chronic liver diseases. He testified to the value of spa treatment in most chronic conditions, mentioning as amenable hepatitis generally but not including malignant conditions. Injury of the liver, acute and chronic, he pointed out might range between any febrile or inflammatory condition, from which recovery might be expected, and the total breakdown of acute necrosis. He laid stress on the recuperative power of the liver, saying that as much as four-fifths of its great expanse might be destroyed when the remaining one-fifth would discharge the duties and develop cells and ducts to that end, a circumstance which he described as "the doctor's trump card." Treatment of the damage might be successful if the damager could be rendered inactive—e.g., if alcohol were cut off. In catarrhal jaundice, usually classed as affecting the ducts, there was often damage to the cells. Recovery here would be obstinate and the coöperation of the surgeon might be necessary. Alluding to what was once a routine procedure in gall-stones—namely, the administration of olive oil—he pointed out that it was a remedy for the flatulence that often formed a most distressing symptom in cholecystitis. Dr. McNee then spoke of the value of the duodenal tube (blunt-pointed) in diagnosis, and concluded by testifying to the great service to medicine of spa treatment through its special medical experience, its amenities, and discipline.

Dr. Curtis Bain read the notes of a series of cases of diseases of the liver, all inflammatory, classified them under their symptoms, and described the common regimen of spa treatment in accordance. Concerning the alcoholic liver he expressed the opinion that alcohol was a poison secondary to cholecystitis and not to be regarded always as the origin. He attributed the good results of spa treatment in liver diseases to the influence, in this order, of (a) discipline —which he allowed was hard to evaluate; (b) liver-packs when skilfully administered; and (c) sulphur water. He then described the results of a series of heroic experiments upon himself with the duodenal tube to ascertain the cholegogic influence of Harrogate water.

Dr. Wilfrid Edgecombe gave the details of treatment at the spa suitable to the liver patient, and mentioned the complicated constituents of the water obtainable from the various sources as accounting for the metabolic effects which were cholagogic, diuretic, and antiseptic; he pointed to the presence of barium as effective in depression. The liver pack, followed by the needle douche, was employed as a counter-irritant, while the stimulating baths should be followed by proper massage. In cases of congested liver, with concentrated dark urine and possibly glycosuria, such a regimen might act like magic. He outlined illustrative cases suggesting the good that followed spa treatment in early cholecystitis and perhaps in the first stages of gall-stones indicated by biliary sand.

Prof. D. P. D. Wilkie spoke of the great value of a preliminary spa course in cases where operation would usually follow. The fat flabby subject was not fit for operation in comparison with one who under strict regimen for a few weeks had lost perhaps two stone in weight and gained in general health and muscular tone. Such properly prepared patients, trained for the ordeal like athletes for a boat race, sometimes might escape operation, a circumstance which he claimed as "a triumph of conservative surgery." He mentioned that delay in operation, in cases of obdurate gall-stones, subjected the patient to the risk of malignancy, and noted that the biliary surgery of to-day thought in terms of general physiology rather than in those of anatomy.

Dr. Manson-Bahr spoke of the progress of therapeutics in tropical disease as having removed large classes of disease from the sphere of spa treatment, and, while he doubted if the once popular term "tropical liver" had ever been an accurate description of an entity, he said that there was ample room for further research into the relations between climate and disease. Undoubtedly the recovery-rate in England was much higher than on the spot in many cases of illness sustained abroad.

Dr. M. B. Ray, president of the Physical Medicine Section, R.S.M., presided at the afternoon session, when a discussion was opened on the

Spa Treatment of Skin Diseases

by Dr. S. Ernest Dore, who commenced by pointing out decisively that it is to resident practitioners in Harrogate that guidance must be looked for as to which varieties of sulphur or saline waters are best suited to particular ailments. He found the trend of present opinion to be in favour of the exogenous causation of skin diseases, a view borne out by the comparative failure of dietetic measures, of internal drug treatment, and of attempts to remove septic material. He claimed eczema as an example, and pointed to the varying virtues attributed to sulphur, as found in the Harrogate waters. He pleaded the impossibility of mentioning all spa methods as directed to different cutaneous disorders, deciding to concentrate attention on a group of congenital diseases of the skin such as ichthyosis, known in its milder form as xerodermia, and erythemato-squamous affections of which psoriasis was the type. With regard to ichthyosis he pointed out that the discomfort was great owing to excessive dryness and scaliness of the skin, difficulty of movement according to the amount of thickening and fissuring, and liability to inflammatory dermatitis. These, he said, may last throughout the patient's life, although there is some tendency to amelioration as age advances. In this affection some lubricating and keratolytic preparation must be applied more or less continuously to the whole body, and for this purpose nothing is better than sulphur in ointment and sulphur baths. The ointment, he said, must not be continued too long or it may itself cause dermatitis, but its use can be repeated from time to time until the skin becomes soft and free from scales, and thus made amenable to baths and emollients. Coming to psoriasis, he said that treatment by baths was most often used and most likely to be successful, and unless scales were removed by alkaline or saponaceous baths, ointments are practically useless though alkaline sulphur waters have in themselves remedial effects. For the extensive erythemato-squamous eruptions such as the pityriases and chronic seborrhœic dermatitis he found mild sulphur baths suitable treatment. Other conditions enumerated by Dr. Dore as susceptible of relief or improvement by proper courses of sulphur baths were Hebra's and Besnier's prurigo, parasitic skin affections, acne, and the generalised pruritus of the senile type, a list which he described as not attempting to be complete; and while laying stress on sulphur, he could not forget the benefits to be obtained in many conditions from chalybeate waters, mud packs, and colonic irrigations to be readily obtained by patients at a centre like Harrogate.

Dr. Haldin Davis spoke amusingly of the view of the great Robert Willans who had associated the prevalence of cutaneous disease in England with the absence of bathing. He spoke highly of spa treatment in skin diseases and instanced its beneficial results on psoriasis and conditions associated with nervous disorder like lichen planus.

Dr. F. A. Bearn (Strathpeffer) mentioned, as two diseases particularly benefited by spa treatment, psoriasis and eczema in the gouty subject.

Dr. Bertram Watson pointed to the value in the treatment of diseases of the skin—"that mirror of the mind"—of mental diversion. In reference to exogenous or endogenous causation he declared his belief in a gouty eczema. He spoke of good results at Harrogate from the treatment of seborrhœic eczema, psoriasis of the chronic limited kind, and acne, while in chronic urticaria he had found colonic lavage with sulphur water useful. Dr. Watson was particularly interesting in his differentiation of the springs of various strengths at Harrogate comparing their actions upon different conditions. He gave figures which showed a very high percentage of skin cases as undergoing successful spa treatment at Harrogate.

Dr. C. W. Buckley (Buxton) said that the time had arrived when dermatology should have more scientific reasoning behind it; not sufficient grounds were forthcoming for particular methods of treatment, so that evidence in favour of procedures depended only upon individual report. He favoured the endogenous view in what he would term gouty eczema.

Dr. Edgecombe spoke of the nervous connexions of skin disease as shown in lichen planus and senile pruritus. Referring to the prescription of regulated diets, he said that the keynote was moderation, and that at Harrogate special diets when ordered would always be obtainable.

Dr. Geoffrey Holmes indicated that where the spa was resorted to for a particular disease a common regimen for diet at the spa could be to a great extent laid down. This did not meet the case at Harrogate, but at all the Harrogate hotels special diets could be obtained in accordance with medical orders for special cases.

Dr. Alfred Cox said that he had heard many criticisms from not unfriendly people, who had visited both British and foreign spas, to the effect that at home there was not effective combination between the municipality, the hotel, and the doctor, for ensuring that the "cures" should be regarded as an organic whole, in which the credit of all parties was concerned.

On Saturday evening a dinner was given at the Hotel Majestic by the Harrogate Medical Society to the delegates and visitors, Mr. D'Oyly Grange presiding. Dr. Bertram Watson proposed prosperity to the British Health Resorts Association, to which Lord Meston, president of the Association, replied. Lieut.-Colonel Byam then proposed the toast of Harrogate, to which the Mayor, Councillor J. H. Newsome, and Mr. D'Oyly Grange replied. The evening closed with a cabaret show and a dance.

The Conference was a great success, the scientific debates being of a practical nature and the social functions, generously organised, being aided by fine weather.

PANEL AND CONTRACT PRACTICE

Insurance of School Leavers

A few months ago the Birmingham insurance committee passed a resolution "that the National Health Insurance Act should be amended so as to bring within its scope all persons who on leaving school enter into insurable employment between the ages of 14 and 16 years," and sent it to every other insurance committee with a request that it might be discussed and adopted. Several committees have discussed the matter; some have agreed with the proposal; others think it is not the time to extend the scope of the Act when sickness claims are so heavy that funds are badly depleted. The fact that no report of discussion on this subject has been received from panel committees or the Insurance Acts Committee may be due to the feeling that doctors ought not to be consulted on such matters; they should just be prepared to treat anyone sent to them under the Act. There are two main reasons why this resolution is popular. The first is that as children are medically inspected and tabulated in the schools up to the time of leaving there is at present a gap in their medical history cards until they arrive at 16 when they become insured under the present Act. The resolution would fill in the gap in those cases where work was obtained on leaving school. The other reason is that it would help to put a stop to the practice of firms who employ children on leaving school and dismiss them at the age of 16 when they become insurable. It may be time for the medical profession to express an opinion on the matter, bearing in mind that the risk would not appear to be large, for most children have had their minor infective diseases whilst at school, and the period from 14 to 16 would not add much to the liability of health insurance.

The Parish Doctor

In a recent issue of *John Bull* a "parish doctor" points out that as his patients have no choice of doctor he has always taken special care to treat them exactly as he would private or panel patients. But these ideals have been wearing thin under the stress of overwork and underpayment. When he started his remuneration was £85 a year or 32*s.* 8*d.* a week for an average of 32·6 services, mostly home visits—almost exactly 1*s.* per service. For this shilling, of which 3*d.* was deducted for income-tax, he had to supply medicines; part of it must be written off for upkeep of surgery and motor expenses, the remainder, if any, was payment for professional services. The rate of payment per insurance service in the same practice was 2*s.* 4*d.*, and this of course did not include drugs. If insurance patients increase in number the payments increase, but the parish doctor's payment remains the same no matter how many patients the relieving officer sends him. They are, moreover, the selected unfit and generally permanently unfit. They are often old people who need a disproportionate amount of visiting. Extra payments under the parish system are few. If sent to a midwifery case by the relieving officer the doctor gets a fee of 10*s.*; if he is called in by the attending midwife the county council pays him two guineas. The council, it should be added, is the paying authority in both cases. For the certification of a person of unsound mind the district medical officer gets a fee of one guinea; if after making a very careful examination he cannot certify the case he gets nothing. It is surely time for the whole system to be overhauled and adequate payment with free choice of doctor substituted.

Arch Supports

These continue to give trouble. It will be remembered (March 10th, p. 544) that a decision of referees given in October, 1933, brought arch supports into the category of splints, and as such to be ordered on the ordinary prescription form and charged to the drug fund. Not many doctors, however, have much experience in ordering the correct arch. It is not sufficient to order Mr. B. a pair of supports without giving details as to the height of the arch; moreover, these supports need frequent adjustment if the support is to do any good. The chemist, as a rule, knows still less about them. He does not stock such things, and when presented with a prescription for a certain size of supports he simply says "I have not any arch supports. You had better go to XYZ who do that sort of work." XYZ are not under contract with the committee and charge the patient for supports. This causes trouble because by this time the patient has heard that he can have these supports "on the panel," so why should he pay for them. It would seem quite obvious that when a patient comes to him with a prescription for arch supports he should send him to some instrument maker of repute with a note asking that firm to deal direct with the patient, but to send the account to the chemist. The chemist would then add his dispensing fee and obtain payment in due course from the insurance committee. When adjustment became necessary the patient would obtain a new prescription and the process would be repeated. But this procedure has not been notified to the chemists. Before the referees came to their decision that arch supports are splints such appliances were often supplied and paid for by approved societies out of additional benefits. The Ministry of Health apparently do not find the position created by this decision at all easy to deal with. It has been suggested that there should be a list of specified splints which can be ordered by prescription on the drug fund, or that there should be a better definition in the regulation of what a splint is, in order to exclude things which a chemist can hardly be expected to supply. A less serious suggestion is that on the analogy of drugs there should be an advisory committee to draw up lists of things that are (*a*) always splints, (*b*) sometimes splints, (*c*) and never splints.

The National Formulary

The Birmingham panel committee has called attention to the difficulties which arise when doctors write prescriptions for medicines under letters which are included in earlier editions of the National Formulary, but are not included in the present edition. It is proper in such cases for the formula to be written in full. There are, however, undoubtedly cases where the intention is to prescribe present formulas, but an old title is erroneously used. For instance, "Mist. Sodæ cum Rheo" is frequently prescribed, although as far as the formulary is concerned this title has been extinct for many years, and to dispense accurately what is ordered it would be necessary to go back to the 1924 edition. No doubt some prescribers wish the "Mist. Rhei Ammon. cum Soda" or "Mist. Rhei Co." of the present formulary to be dispensed, but to refer to the doctor in all such cases is not practicable. It should not be forgotten that there have been numbers of dispensing establishments opened within the last few years which do not possess copies of the old editions of the formulary. Insurance practitioners elsewhere would be wise in their own interests to make certain that they are using the latest nomenclature when ordering a stock, otherwise their cost of prescribing may show an increase which they did not intend.

PUBLIC HEALTH

Local Authorities and Insulin

THE text of the Finance Bill, issued last week, makes known the Government's intention to place insulin on the free list under the Import Duties Act. Whatever effect, if any, this may have on the price of insulin in this country, the decision is a public recognition of the peculiar importance of insulin as a remedy. In 1925 Parliament passed a short Act enabling Scottish local authorities to arrange for providing medicine and treatment for diabetic patients. A recent political conference at Liverpool urged the Minister of Health to give serious attention to the provision of treatment (either free or on reasonable terms) for such patients in England. He has replied that English local authorities can act for the purpose under Section 133 of the Public Health Act of 1875. Referring as it does to legislation enacted long before the discovery of insulin, the reply deserves fuller explanation. The section gave local authorities a general power (subject to the sanction of the Minister) to provide "a temporary supply of medicine and medical assistance for the poorer inhabitants of their district." The Minister, it is understood, sanctioned under this enactment a free supply of simple medicines for hop-pickers in certain rural districts. Specific exercises of the statutory power will be found in the Diphtheria Antitoxin (Outside London) Order of 1910 and the corresponding order for London of the same date, and also the Public Health (Cerebro-spinal Fever) Regulations of 1918. The latter sanctioned the provision, by the councils of administrative counties and of county boroughs, of serum and vaccine together with the necessary apparatus for their use. As regards antidotes and remedies against infectious disease, many authorities have taken special power by local legislation for their provision and supply to medical practitioners with or without charge; an instance of this familiar clause will be found in Section 65 of the Wimbledon Corporation Act of last year. As regards insulin there is, as the Minister observes, the general power under the 1875 Act, but it does not appear that he has given any general sanction as he did in the case of diphtheria antitoxin or cerebro-spinal fever serum. Section 133, which appeared in an earlier form in the Sanitary Act of 1868, looks a little old-fashioned now. Some limitation seems to be connoted by the words "temporary supply," and the reference to the "poorer inhabitants" introduces an invidious element. The consolidation of public health enactments, now in hand, will give the draftsman a chance to modernise the language in the light of present requirements.

A Radiologist for Hammersmith Hospital

The London County Council has decided to make provision for a radiological department at the Hammersmith Hospital which shall be the consultative centre for the whole of the L.C.C. hospitals service. Cases will be sent to the department from other hospitals for expert opinion on diagnosis or treatment. It is recognised that the officer in charge of this department, associated as it will be with the British Post-graduate Medical School, should be of outstanding ability, and it is proposed to make the appointment early in order that his services may be available on questions relating to the equipment and planning of the department. The proposed salary is £1500 a year, the appointment to take effect, if possible, on July 1st.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 5TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 2 (last week 9); scarlet fever, 3005; diphtheria, 1077; enteric fever, 23; acute pneumonia (primary or influenzal), 1021; puerperal fever, 57; puerperal pyrexia, 128; cerebro-spinal fever, 32; acute poliomyelitis, 6; encephalitis lethargica, 10; dysentery, 8; ophthalmia neonatorum, 106. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 14th–15th was as follows: Small-pox, 9 under treatment, 3 under observation (last week 8 and 0 respectively); scarlet fever, 1598; diphtheria, 1684; measles, 2740 (last week 2857); whooping-cough, [illegible]; puerperal fever, 36 mothers (plus 12 babies); encephalitis lethargica, 259; poliomyelitis, 3; "other diseases," [illegible]. At St. Margaret's Hospital there were 13 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 118 great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 91 (33) from measles, 7 (0) from scarlet fever, 48 (9) from whooping-cough, 34 (10) from diphtheria, 42 (12) from diarrhœa and enteritis under two years, and 68 (14) from influenza. The figures in parentheses are those for London itself.

Measles is still diminishing, but 11 fatal cases were reported from Liverpool, 7 from Newcastle-on-Tyne, 5 from West Ham, and 3 from Newcastle-under-Lyme. Bradford, Sunderland, and Northampton each reported a death from enteric fever. Whooping-cough proved fatal in 8 cases at Liverpool, 6 at Birmingham, 3 at Walsall. No great town recorded more than 2 deaths from diphtheria.

The number of stillbirths notified during the week was 282 (corresponding to a rate of 41 per 1000 total births), including 41 in London.

EDINBURGH ROYAL INFIRMARY.—The Edinburgh dean of guild court has approved plans for a new venereal diseases and dermatological department which is estimated to cost £40,000.

CORRESPONDENCE

SANITY IN A MENTAL WARD

To the Editor of THE LANCET

SIR,—Unavoidable circumstances have prevented me from reading till now the annotation with the above heading in your issue of April 28th (p. 909). May I extract the following passage from it in order to point what I believe to be the obvious moral? A "delirious" patient is consigned to the "mental ward of a public hospital." (Incidentally, is not such a place well-nigh legendary?) Your annotator comments:—

> "Ideally it would be possible to have two wards in a general hospital in each large centre reserved for delirious and confused patients whose mental symptoms followed upon physical disease." This arrangement "might lead to general physicians and psychiatrists working in closer association; some general trained nurses would acquire greater acquaintance with some forms of mental disorder; and the medical students would have occasional opportunities of seeing acute psychoses without being wholly dependent upon journeys to distant hospitals. . . . So far as the student is concerned the divorce of ordinary clinical experience from his acquaintance with acute psychotic and psychoneurotic disorders leaves him unprepared for the exigencies of practice when at any time he may need to deal with them."

The moral is that there should be in every city with a medical school a complete indoor and outdoor psychiatric clinic in association with and a recognised part of the general hospital centre. Large towns, without a school, can follow suit. Here such patients as the above—and many other cases of psychosis—could be dealt with, and the skilled coöperation, teaching, and experience referred to could be provided, and research in its highest forms carried out.

This provision, regarded as elementary, and long since made on the continent, has been urged for this country to my personal knowledge for 40 years—and probably longer. But apart from the Maudsley Hospital (a special case), nothing has been done. I read that Their Majesties are to honour with a visit a new mental hospital. The latest of the kind it may be, nevertheless of a familiar kind; not a fundamentally new conception. This is as far as we have got. The occasion is doubtless auspicious. It would be far more so were it concerned with the inauguration of the psychiatric clinic we have so long been pleading for.

I am, Sir, yours faithfully,

EDWIN GOODALL.

Hove, May 9th.

ORAL IMMUNISATION AGAINST TYPHOID

To the Editor of THE LANCET

SIR,—In your issue of April 7th (p. 764) your Paris correspondent gave an account of the annual meeting of the Marseilles Medical Society at which the endemicity of typhoid fever in that city was considered. It was decided at this meeting to recommend preventive vaccination, but exclusively by subcutaneous injection, vaccination by the mouth, according to the Marseilles practitioners, giving uncertain results, an immunity of a few weeks only, and a false sense of security. But in my opinion immunisation by the mouth is to be considered, both in the light of statistics and of experience, as certain as parenteral vaccination, the mechanism of the establishment of immunity being precisely the same in the two cases. The only difference between the results lies in the fact that the oral route seems to establish immunity more rapidly than the hypodermic route. We have seen for instance, during an epidemic of typhoid at the Prytanée Militaire de la Flèche, where the pupils were vaccinated fifty-fifty by the two methods, that among those vaccinated by the mouth the epidemic was stayed much more rapidly than among those immunised by T.A.B.

More than four million persons have been vaccinated against typhoid, cholera, and bacillary dysentery by the mouth, of these some 250,000 under the control of public sanitary authorities. All without exception have declared that the two modes of vaccination had equal value. I do not wish to insist here on the Japanese experience that the oral results are superior to the hypodermic; but comparative vaccinations carried out in India under the control of the Health Commission of the League of Nations, and based on a large number (31,700) of subjects led Dr. Russell to conclude: "The bilivaccine (full dosage) and anti-cholera vaccine (double dose) give much the same degree of protection from attack." Dr. Cluver, who undertook the same vaccinations under the ægis of the Government of South Africa, estimates that the results obtained by oral vaccination are more favourable than those given by injection.

There remains the question of the duration of immunity, said to be "only for a few weeks." This statement seems to me gratuitous. None of the sanitary institutions quoted, nor any government, has reported that oral immunity lasted a shorter time than hypodermic. It is possible that among vaccinated persons there could be found a small minority who cannot be protected, at all events completely; but this minority is found equally among "parenterals." During the war the only method of vaccination was by injection and that did not prevent, among 2334 typhoid cases nursed at Bar-le-duc hospital, the discovery of 469 cases who had been vaccinated by injection one or more times and had contracted typhoid one to eight months after vaccination.

I have only attempted to bring to your knowledge rectifications based entirely on controlled facts, leaving your readers to draw their own conclusions in favour of this or that method of vaccination.

I am, Sir, yours faithfully,

Paris, May 3rd. L. F. DESTOUCHES.

DIAPHRAGMATIC HERNIA

To the Editor of THE LANCET

SIR,—With reference to the case of congenital diaphragmatic hernia reported by Dr. G. H. Greenway in your issue of March 24th (p. 628), and his request for information of other recorded cases, may I draw his attention to the case of G. H. Dodds and J. D. S. Flew (*Univ. Coll. Hosp. Mag.*, 1928, xiii., 43) and to the letter of Dr. Herbert R. Spencer in the subsequent issue (p. 123) where he draws attention to four specimens in the University College Hospital Museum, and to the value of the Obstetrical Transactions, particularly the last (index) volume of 1907 as a record of obstetrical and gynæcological publications from 1860 to 1907. In Dodds and Flew's case, the infant lived eleven days. The hernia was through a persistent pleuro-peritoneal sinus on the left side and was therefore without a hernial sac, and the left side of the thorax contained the stomach, jejunum, ileum, cæcum, ascending colon, transverse colon, spleen, pancreas, and left lung.

I am, Sir, yours faithfully,

STEPHEN K. MONTGOMERY, M.D., D.R.

Johannesburg, April 25th.

BENZENE AND BENZINE

To the Editor of THE LANCET

SIR,—In THE LANCET of May 12th (p. 1025) there appears a report of an inquest on a cellulose sprayer, in which there is reference to "benzine" poisoning. May I point out that this should be "benzene" (benzol)? Benzine, the distillate of petroleum, does not, as far as I am aware, ever produce chronic poisoning. Benzene, a coal-tar distillate, on the other hand, has long been known under certain conditions to produce a form of aplastic anæmia. I draw attention to this because reports of such cases are extracted and repeated, and confusion consequently arises on the relative toxicity of these two bodies.—I am, Sir, yours faithfully,

JOHN C. BRIDGE.

May 15th.　H.M. Senior Medical Inspector of Factories.

THYROIDECTOMY FOR HEART FAILURE

To the Editor of THE LANCET

SIR,—In your issue of Feb. 10th appeared a leading article drawing attention to Berlin's work on thyroidectomy for heart failure (Amer. Jour. Surg., 1933, xxi., 173). Perusal of your article and reference to Berlin's work encouraged me to operate on the following case, and the result up to date has astonished me.

On March 9th a woman aged 66 was admitted to the Buchanan Hospital for heart failure and ? ovarian cyst. Her medical history was shortly as follows:

1898.—Rheumatic fever.
1914.—Myomectomy and ventro-fixation of uterus.
1932.—Multiple arthritis. The patient was told her heart was affected.
1933.—Two heart attacks in October, has been in bed on and off ever since.
1934.—Patient noticed a lump on right side of abdomen.

On admission the patient was seriously ill, cyanosed and dyspnœic with œdema of ankles, congestion of pulmonary bases, and enlargement of liver. A diagnosis of congestive heart failure due to mitral stenosis and aortic regurgitation was made.

On April 22nd, the day before operation, the patient's condition was as follows: (1) Cyanosis of lips and venous congestion of neck. (2) Œdema of ankles. (3) Liver 2 in. below costal margin and tender on palpation. (4) Albuminuria. (5) Moist crepitations at both pulmonary bases and dullness at right base. (6) Exercise tolerance test. Resting pulse-rate 90 and irregular. The patient was told to sit up and lie down ten times. She became dyspnœic and the pulse dropped to 84 and became more irregular.

The patient's mental outlook was pitiable. She was thoroughly sick of life, and readily signed a special permit for operation in which it was stated that she might not return from the theatre alive. A complete thyroidectomy under avertin and novocain block (Labat's method) was carried out on April 23rd, Berlin's technique being followed. Two parathyroid bodies were demonstrated in the left tracheo-œsophageal groove. Oxygen was administered during the operation.

The patient stood the operation well and examination on May 13th, 20 days after operation, revealed the following: (1) Resting pulse-rate 72 and regular; exercise tolerance test (as above); the pulse-rate rose to 80 and gradually dropped to 72 at the end of 1½ minutes, no irregularity developing. (2) Liver dullness to costal margin, a decrease of 2 in.; no tenderness on palpation. (3) Breath sounds weak but audible at both bases; no adventitious sounds. (4) No œdema of ankles. (5) No albuminuria. (6, B.M.R. Reid's formula 15·5 (before operation it was 25·4).

This patient's mental outlook is completely changed. Some of her remarks are:—

"I have not felt like this for years . . . I sleep as I never hoped to sleep again . . . I have no pain in the heart, and none of the awful fluttering I used to have . . . I can now lie comfortably in any position, and do not feel the lack of air. . . Even if I don't get any better, it will have been well worth while."

I am indebted to Dr. Paul Kuhne for the medical notes and for the administration of oxygen during the operation.　I am, Sir, yours faithfully,

D. LIGAT.

Buchanan Hospital, St. Leonards-on-Sea, May 14th.

X RAY CARCINOMA

To the Editor of THE LANCET

SIR,—I wish to offer certain testimony confirming the contention of Mr. W. Sampson Handley (THE LANCET, Jan. 20th, p. 120) that, if any suspicious warty area of a hand of a rontgenologist is found to be a carcinoma, the patient's safety demands a complete gland dissection, so soon as glandular enlargement can be detected in the axilla or in the supratrochlear gland of the affected side. Mr. Handley even contends that precaution is wise even in cases where the glands are normal to palpation, though it cannot then be so strongly urged. The object of his operation is to cut the main line of dissemination at an early age.

In an article entitled A Pioneer Roentgenologist (Eugene Rollin Corson, M.D.), I published (Amer. Jour. Roentg., 1931, xxvi., 759) the following testimony of Dr. Corson's experience:—

"While Dr. Corson was preparing his paper on the normal movements of the carpal bones, a work not previously done, the exposure before the fluoroscope, after a long delay of 10 years, showed up with epitheliomata on the four fingers of his left hand, three of which were subsequently amputated. At the earnest advice of Prof. Halstead, of the Johns Hopkins Hospital, he had all the lymph glands removed from the axilla, and he feels assured that this timely operation has prevented the spread of the malignancy. He would earnestly advise all sufferers from over-exposure to adopt this radical measure.

"The loss of his fingers debarred him from further surgical practice. He firmly believes that had his co-workers at that time (and he has in mind especially his friend, Dr. E. W. Caldwell, whose early death was an irreparable loss to our profession), who have since given their lives to science, had had the advantage of this early radical treatment they might still be among us to-day."

Undoubtedly Mr. Handley's advice is excellent. It is to be hoped that rontgenologists who may suffer malignant changes upon the hands will have the courage to submit to this radical procedure promptly and early. Dr. Corson is still alive and well. His operation occurred about 1906.

I am, Sir, yours faithfully,

Kansas City, Missouri, May 1st.　E. H. SKINNER.

DISCLAIMERS

Mr. A. R. PATTISON writes: "In its issue of May 10th the *North Mail* published a laudatory article in extravagant phrases, referring to the work of the neurological surgeon at the Newcastle General Hospital. No name was mentioned; but it must have been obvious to anybody remotely acquainted with the facts that this article referred to me. The harmful effect of the article has been aggravated by the fact that certain charges for maintenance, which are made from time to time by the hospital authorities, have been quoted in a sensational manner as representing my customary fees. I should like to state emphatically that this article was published entirely without my knowledge or consent. I should be obliged if you would publish this disclaimer in the usual manner."

Mr. ALECK BOURNE, F.R.C.S., writes: . "My attention has been drawn to a paragraph in the lay press of May 4th which implies that I am a 'super-specialist' (whatever that may mean) in a small corner of obstetrics. I have never claimed such a doubtful distinction, it is an absurd untruth, and the paragraph was inserted without my knowledge."

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

FREE TREATMENT FOR EX-SOLDIERS

THE powerful "veterans' lobby" at Washington has won another victory and in doing so has overcome the still popular influence of President Roosevelt. The latter, faithful to his pre-election pledges, had vetoed the Independent Officers' Appropriation Act for the year 1935. This legislation, carried by the necessary two-thirds majority in both houses of Congress over the President's veto, involves an increased expenditure by the Veterans' Administration of $83,000,000 annually. Any veteran not dishonourably discharged who suffers from any disease, disability, or defect (whether war-connected or no), and who makes a statement under oath that he cannot pay for the treatment of same, will receive free treatment and hospitalisation or domiciliary care through the Veterans' Administration. Various other privileges are also restored to ex-combatants, both of the World War and of previous wars in which the United States has engaged. As I have previously reported, medical care is now available to all indigent persons through the provisions of Regulations No. 7 of the Federal Emergency Relief Administration. The latter regulations also provide for nursing care in the home when necessary, but make no provision for hospitalisation. The superior facilities of the Veterans' hospitals will doubtless attract to them the ailing veterans and so the practising physicians of this country will lose the fees to which they would have been entitled under Regulations No. 7.

THE PERIODIC MEDICAL EXAMINATION

The idea of a periodic examination for the apparently well is believed to have originated with Dr. Horace Dobell in England.[2] It was advanced by Dr. George M. Gould in this country in 1900. But it was not until several years later that the Life Extension Institute was founded and began to popularise the idea. The organised profession of medicine has never become reconciled to certain features of the service offered by this institute, but in 1922 the periodic examination idea was blessed and formally adopted by the American Medical Association. For 12 years its advocacy has been orthodox doctrine. Now, however, a State medical association —that of Massachusetts—has put on record its condemnation of the practice. For it they would substitute early consultation for every trivial symptom. This admittedly would detect such diseases as diabetes and pulmonary tuberculosis at a somewhat later stage than they are detected by routine exmination of the apparently healthy. Moreover, early consultation still leaves the doctor a practitioner of curative rather than of preventive medicine, whereas the routine examination, as the New York Academy of Medicine points out,[3] educates the public to look upon his medical adviser as a steady mentor for every member of the family, and not merely as a consultant in the emergencies of disease. There is no denying, however, that the great majority of doctors in this country show no disposition at present to adopt the rôle of steady mentor to those who do not complain of being unwell.

IRELAND

(FROM OUR OWN CORRESPONDENT)

UNIVERSITY REPRESENTATION IN THE IRISH FREE STATE

UNDER the constitution of the Irish Free State each of the universities in the country at the time the constitution was adopted became entitled to elect three members to the Dail. The electorate of the National University of Ireland contains the names of between 4000 and 5000 voters, that of Dublin University a little over 3000. A graduate has the option of voting either in his university constituency or in his local constituency, but he has not a dual vote. The number of votes required to elect a member for the university is very much less than is required in an ordinary constituency, and this fact has raised the objection that graduates have a special privilege not possessed by the ordinary voters. The present government accepts this view, and has introduced in the Dail and carried through its second reading a Bill to abolish university representation. As the government refused to leave the measure to the free vote of the House, it will no doubt pass the Dail, but its journey to the statute-book may possibly be delayed by the Senate. In any event it only comes into operation at the first general election after it becomes law. It is not denied that the members hitherto returned by the universities have given useful service to the State. In particular the medical profession is likely to regret the disappearance of the university franchise, for since 1918, first at Westminster and later at Dublin, the University of Dublin has consistently returned one medical man among its representatives. There is no doubt that the universities, both in Great Britain and in Ireland, can and do send into public life men of a type which would be unlikely to be chosen by the ordinary constituency.

CHILD GUIDANCE COUNCIL.—This council offers two fellowships, each of £300 tenable for a year, for half-time work at the London Child Guidance Clinic. Particulars will be found in our advertisement columns.

TRANSFER OF HEATHERWOOD HOSPITAL, ASCOT.—The London County Council has been approached to take over the hospital for surgical tuberculosis in children built by the United Services Fund in 1922 for the assistance of ex-Service men and women. The hospital, which lies near Ascot, on the London-Reading road, provides beds for 136 children on a site 55 acres in extent, the original mansion being used as resident quarters for doctors and nurses, and there is ample space for extension. The L.C.C. was expecting to take over the hospital in 1938, but in view of the pressing need for economy on the part of the United Services Fund has agreed to do so at the end of next September.

OBITUARY

FRANCIS SEYMOUR KIDD, M.Ch. Camb., F.R.C.S.

LATE SURGEON TO THE LONDON HOSPITAL

THE death occurred on Saturday, May 12th, at his country house at Barton Stacey, Hampshire, of Mr. Frank Kidd, the well-known surgeon and urological specialist. Although he was only 56 years of age, the event was not unexpected as his breakdown in health had been prolonged.

MR. FRANK KIDD

[Photograph by Gee

Francis Seymour Kidd, widely known as Frank Kidd, was one of the younger members of the large family of the late Dr. Joseph Kidd of Blackheath. He was educated at Winchester and Trinity College, Cambridge, and graduated with honours in the Natural Sciences Tripos, taking later the degrees of B.Ch. in 1903 and M.B. in 1905. He completed his medical education at the London Hospital, where he held a surgical scholarship and where he afterwards filled the house appointments and became demonstrator of anatomy and surgical registrar. He did some post-graduate work at Berlin, proceeded to the M.Ch. degree and the English fellowship and this was followed by election to the staff of the London Hospital.

The direction of his special interest was almost at once indicated by the publication of a book on urinary surgery in 1910. At the time that this book appeared few outside a particular circle were aware of the progress that had been made in the surgery of the urinary organs, and Kidd's book drew pointed attention to the great advances made during the ten years previous to its publication which were manifested both in diagnosis and treatment. It was a chronicle of new knowledge, made by a man intimately associated with its development. During those ten years the technique for catheterisation of the ureters had been simplified, allowing an estimate of the physiological power of each kidney to be made more readily; at the same time bacteriological research associated with the urinary tract had added to the knowledge of the infections of this system, while the introduction of the X rays for the detection of calculi in the kidney, ureter and bladder was increasing in a practical manner the surgeon's capacity of diagnosis. The great developments of the surgery of the prostate now followed, and all these aspects of urology up to date Kidd described in a book which was also excellently arranged and easy to read. He obtained, and rightly, a very large consulting and operating practice, and from time to time wrote out his experiences in an informing manner in the columns of the medical journals and in well-known compilations and encyclopædias. His clinical records, though numerous, were never made without reason—they always contained a lesson. For example, in describing the case in our columns of the largest calculus which he had ever removed from the pelvic portion of the ureter—the stone measured 2¼ in. in the long diameter and 1 in. in the short diameter (see THE LANCET, Jan. 17th, 1920, p. 151)—he noted the absence of preliminary indications of the condition, and concluded from his own work that as a general rule the larger the stone the fewer the symptoms; a practical hint of the first importance. Similar references to medical literature throughout a long period might be given in testimony of Kidd's surgical judgment, operative dexterity, and also to his wide reading. For instance, as president of the section of urology of the R.S.M. he delivered an address on purpura of the urinary tract (vide THE LANCET, May 5th, 1928) in which the difficulties of diagnosis were analysed and the ætiology and treatment discussed in reference to a series of illustrative cases. The address introduced the audience to much new bacteriological and technical knowledge, while its practical message was to give reasons for the fact that urologists had often been led to remove the kidney on suspicion of non-existent neoplasms, whereas neoplasms of the kidney are both comparatively rare and when present do not form a common cause of hæmaturia. While still assistant surgeon to the London Hospital he took charge of a genito-urinary department at the hospital. He became full surgeon to the institution some 15 years ago, and was also surgeon to St. Paul's Hospital for diseases of the genito-urinary organs and skin, where much of his operative work was done.

Mr. Frank Kidd married Stella, daughter of the late Mr. W. Williams, of Langland, and leaves three sons. He had been, when at Winchester, a prominent footballer, and later obtained his University blue for hockey and became a member of the English team in some international contests.

MEREDITH YOUNG, M.D. Edin., D.P.H.

LATE M.O.H., CHESHIRE COUNTY

WE regret to record the death of Dr. Meredith Young which occurred at Chester on May 7th at the age of 64.

Meredith Young was born at Waterloo, Liverpool, the son of the Rev. James Young, and was educated at Bradford Grammar School and at the University of Manchester, completing his professional training in Edinburgh. He graduated as M.B., C.M. Edin. in 1892, taking honours in a series of subjects, and immediately entered the public health service. From 1892 to 1897 he was M.O.H. for Brighouse, during the next three years he acted in the same capacity at Crewe, from 1900 to 1908 he was M.O.H. for Stockport, and then, following a year of service as M.O.H. for the metropolitan borough of Marylebone, he became M.O.H. for Cheshire, a post which he held for 25 years, retiring in 1932.

In the course of filling these appointments Meredith Young proceeded to the M.D. Edin., and took a public health diploma at the University of Manchester and also in London, while in 1907 he was called to the Bar of Lincoln's Inn. Out of his great experience he found that he had the material for much informative authorship and lecturing. He wrote on the clinical and public health aspects of small-pox, on the control of common lodging-houses in the *British Medical Journal*, and on the methods of treating infective conditions of the throat in *The Lancet* and *The Practitioner*, while in 1916 he published an extension of lectures delivered in a special course of

The Cambridge Graduates' Medical Club

The annual dinner of this club was held at the Langham Hotel, London, on Wednesday, May 9th, with the president of the club, Dr. H. Morley Fletcher, presiding. Although the rule of the club admitted no speeches, the president broke the rule by telling the guests in a few words that this was the fiftieth dinner of the club, and took occasion to make some interesting references to its past history. At the close of the dinner Prof. Langdon Brown proposed Dr. Morley Fletcher's health.

University of London Medical Graduates' Society

The annual meeting of this society was held at the Langham Hotel, London, on May 8th. Mr. W. McAdam Eccles was elected president, Sir Charlton Briscoe honorary treasurer, and Mr. W. E. Tanner joint honorary secretary. At the dinner which followed, Sir Henry Brackenbury was the guest of the evening and the retiring president, Lady Barrett, replied to the toast of the society.

Longer Training for Blind Masseurs

The course for blind students at the massage school of the National Institute for the Blind is to be extended from 18 months to two years. The extension is considered necessary because of the wide range of subjects taught which now include massage, remedial exercises, and medical electricity.

Diet in Hotels at a Spa

A scheme has been evolved at Bath whereby visitors requiring special diet will receive a card from their physician which they will hand to the head waiter or manager of their hotel, who will then see that the instructions are carried out. The names of dishes and drinks to be avoided will be deleted from the list.

East-End Maternity Hospital

The clinical report of this hospital, which is in Commercial-road, states that last year there were 1403 in-patients and 369 out-patients, a total of 1772; there were no maternal deaths. There was one case of eclampsia and one requiring Cæsarean section.

The Guardianship Society

This society, which has its headquarters at Brighton, has now been in existence for 21 years. Its work for the care and the supervision of the mentally and physically defective is well known, and no fewer than 84 public authorities are now invoking its assistance. In 1933 there were 1077 patients on the books, and in addition 170 cases were visited voluntarily, helped, or advised. Besides this after-care work the society has for nine years maintained a clinic for nervous disorders with Dr. G. H. Harper-Smith as mental specialist, where 65 new patients have attended during the year.

A Visit to a Wild Flower Sanctuary

The Green Cross Society which, as already announced (March 24th, p. 662), is organising a visit to Norway for the study of wild flowers, informs us that the start from Newcastle-on-Tyne has been postponed until July 14th, to suit the convenience of the Norwegian botanists, Dr. E. Christophersen and Mr. Johs. Lid, who are to guide the party. Ample opportunity is offered for the exploration of sanctuaries where rare plants have survived from the ice age. The inclusive cost of the ten days' trip, Newcastle to Newcastle, is 20 guineas, or 14 guineas for any willing to travel third class from Newcastle to Bygdin via Oslo.

British Institute of Radiology

The annual general meeting of this institute will be held on Thursday, May 31st, at the hall of the institute, 32, Welbeck-street, London, W., at 8 P.M. Mr. H. A. Edgerton will read a paper on the measurement of X ray quality by a photographic method and Mr. A. J. Minns one on the technical aspects of short-wave therapy.

A medical meeting will be held on Friday, June 1st. A visit will be paid to the Cancer Hospital, Fulham-road, London, S.W., at 11 A.M., and at 5 P.M. Dr. J. V. Sparks will give a short communication on radiographic demonstration of calcification in cardiac valves. A series of paper films by Dr. Sparks with special reference to chest cases will be on view at the institute on Thursday and Friday, and members are invited to report their experiences with paper negatives.

Public Health Services in South Africa

During the debate on the Budget in the Union House of Assembly, Capetown, on April 17th, Mr. Jan Hofmeyr, the Minister of the Interior, made a statement on the public health services of the Union. These services have lately been largely curtailed, but are now not only to be restored but largely extended. Mr. Hofmeyr outlined among other things a campaign against tuberculosis embracing the establishment of subsidised clinics in all the larger towns, the enlargement of the Nelspoort Sanatorium to serve the whole Union, and hospital provision for advanced cases. The scheme is of particular interest to the Transvaal, where 50 beds at the Springkell Sanatorium are being placed at the disposal of the health department, and where accommodation is being provided for non-European cases at Rietfontein. The Minister's new policy makes provision for the welfare of the native and coloured people, and a fact-finding commission is to be set up. At the same time native medical "aids" are to be trained and appointed to combat the excessive infantile and maternal mortality in the Union.

Royal Medical Benevolent Fund

During the first quarter of this year £3674 has been voted in grants as against £3489 during the corresponding period of last year. The following are particulars of a few cases recently helped.

M.B., aged 47, married, daughter age 10. On leaving the army after the war, the applicant had no practice to return to, and having developed disseminated sclerosis he was not capable of undertaking the medical work of an arduous practice. A county council in August, 1930, appointed him medical officer, in which post he made a great effort to carry on. His condition did not improve, and finally he had to resign in August, 1933. He has a pension of £100, and his wife's private income is £20. Fund voted £10 in four instalments for a period of one year.

Widow, aged 32, of M.B. Her husband served abroad and died from tuberculosis at the age of 33 in February, 1934, leaving the widow and two children, a boy of 7 and a girl of 5. The widow is entitled to a pension of £60 and allowances for the children of £45. A life policy when invested will yield £35. Her total income is £140. No relations can help. Fund granted £26 in four instalments over a period of one year.

Daughter, aged 69, of M.R.C.S., has been working for her living for over 30 years. She and a cousin ran a boarding house up to two years ago when they had to give up owing to local competition. They moved to a smaller house with a view to taking lodgers. Only a little money is now earned. The cousin has the old age pension of £26 but the applicant is not eligible till next year. Fund grant £26 in four instalments over a period of one year, and is endeavouring to get other assistance for these two ladies.

Cheques should be made payable to the hon. treasurer of the fund, 11, Chandos-street, Cavendish-square, London, W.1.

National Association for the Prevention of Tuberculosis

The twentieth annual conference of this association will be held in the County Hall, Westminster Bridge, London, S.E., on June 14th and 15th under the presidency of Sir Robert Philip, and will be opened by Sir Hilton Young, the Minister of Health. The conference will take the form of an all-round discussion on the national tuberculosis scheme, and it will consider the national system of combating tuberculosis which was inaugurated by the report of the departmental committee on tuberculosis (1912–13). The first address will be given by Lord Astor, who was chairman of this committee. Other speakers at the opening session will be Dr. A. Salusbury MacNalty, senior medical officer of the Ministry of Health, Dr. N. D. Bardswell, principal assistant medical officer to the London County Council, and Sir John Robertson, professor of public health in the University of Birmingham. In the afternoon the discussion will be mainly concerned with the *tuberculosis dispensary* and the speakers will be Dr. G. Lissant Cox, central tuberculosis officer of the Lancashire county council, and Dr. Melville Dunlop, of the tuberculosis department of the University of Edinburgh. At 10 A.M. on June 15th the discussion will be continued and will deal with residential institutions. The speakers will include Dr. James Watt, Dr. R. C. Wingfield, Dr. J. B. McDougall, and Dr. F. R. G. Heaf. The names of delegates and private members who wish to attend should be sent as soon as possible to the secretary of the association, Tavistock House North, Tavistock-square, London, W.C.1.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Unemployment Bill

On May 14th in the House of Commons Sir H. Betterton (Minister of Labour) moved the third reading of the Unemployment Bill.

Mr. Lawson moved :—

"That this House declines to assent to the third reading of a Bill which removes from Parliament its direct responsibility towards those who are denied employment as a result of the present industrial system, fails to recognise the disquieting evidence of malnutrition and to provide adequate maintenance for the unemployed and their dependents, confirms and perpetuates a vicious means test originally imposed as a temporary expedient, throws upon a section the burden of a debt which should be borne by the whole community, and, by exacting a contribution from local authorities in aid of a national service, inflicts hardship upon areas where, through national neglect, industry has been allowed to decay."

After debate, the motion for the rejection of the Bill was negatived by 421 votes to 67 and the Bill was read the third time.

Road Traffic Bill

The Road Traffic Bill was further considered by a Standing Committee of the House of Commons on May 8th.

Mr. Stanley said that although he had great confidence in the effect of the speed limit he did not claim the knowledge of the future and the absolute certainty of those who opposed the clause and said that it was bound to fail altogether. He was prepared to face the possibility that it might prove a failure. If it should prove a failure it would be better that it should be allowed to lapse rather than that it should be allowed to drag on a miserable existence years after it had been found to be unsuccessful. But three years was too short a time in which to bring the speed limit into force and to map out the areas to which it should apply, and if the mover of the amendment would agree to make the experimental period one of five years ending in 1939 he would be prepared to accept it.

Lieut.-Colonel Moore-Brabazon agreed to this suggestion, and the amendment making the speed limit applicable to the end of 1939 was agreed to.

When a general discussion on the speed limit in the built-up areas and on the definition of those areas took place, Sir E. Graham-Little said he hoped that the Minister would not be put off his intention to use every possible likely device to decrease the toll of accidents. He particularly deprecated any suggestion that they ought to wait and see the effect of one process and then try another process and so on. Speaking as a medical man, he would ask the members of the Committee who had raised such suggestions whether, supposing they were desperately ill, they would accept the suggestion from a physician that they should try one remedy and see how it worked and then try another instead of trying everything that medical science could suggest. He hoped that the speed limit would not be entirely at the mercy of Orders, but that there would be some definite settled principle which would be maintained.

DOCTORS AND THE SPEED LIMIT

In the House of Commons on May 15th, in considering Clause 3 of the Road Traffic Bill which proposes to give exemption from the speed limit to vehicles used for fire brigade, ambulance, or police purposes, Mr. T. Smith proposed an amendment extending similar exemption to cars used by medical men. He said that the purpose of the amendment was to meet the needs of doctors who were summoned to urgent cases.—Mr. Llewellyn Jones said he thought that the result of the proposed amendment might be that any doctor would be able to exceed the speed limit at any time and set up the defence in the event of a prosecution that he was on his way to an urgent case.—Mr. Oliver Stanley (Minister of Transport) said that he could not recommend the Committee to accept the amendment, although he quite appreciated the purpose in view. He had tried to find some way in which this matter could be met, but he had found great difficulty. It would be quite impossible for the police to detect, when a car was going along the road, whether a medical man was going to an emergency case or not. The exemption proposed in the amendment might relieve a doctor from a prosecution, but he might be delayed by the police and everyone was anxious to avoid delay in cases of emergency.—Mr. Grenfell suggested that the matter might be met by doctors being allowed to carry distinctive marks on the roads.—After further discussion, the amendment was withdrawn.

HOUSE OF COMMONS

WEDNESDAY, MAY 9TH

Verminous Houses in Sheffield

Mr. Hamer Russell asked the Minister of Health whether he was aware that the medical officer of health of the city of Sheffield, although possessing abundant evidence of bug-infested property, had no power to eradicate this nuisance, and that alternative accommodation could not be sanctioned for the tenants concerned on the ground that the property was not slum property; and whether, in view of the danger to public health arising from the existence of bug-infested property, he would make investigations and, if advisable, issue compulsory orders.—Mr. Shakespeare, Parliamentary Secretary to the Ministry of Health, replied: Under Part IV. of the Public Health Act, 1925, which is in force in the city of Sheffield, the corporation have power to secure the cleansing of verminous premises, and when this is done it is not necessary to provide alternative accommodation. My right hon. friend will be glad to make inquiries about one case, which my hon. friend has brought to his notice, in which it is suggested that cleansing is impossible owing to the nature of the premises infected.

THURSDAY, MAY 10TH

Female Officers in Prison Service

Colonel Goodman asked the Home Secretary how many appointments to matronship had been made from candidates outside the prison service during the last two years to the nearest convenient date; the number of applicants for each of the posts from established female officers; and if in future appointments he would take into consideration the experience gained by years of contact with all classes of female prisoners on the part of existing female officers.—Sir John Gilmour replied: During the two years ended 30th April ten appointments were made to the post of matron in male Borstal institutions, seven of them being filled by persons from outside the prison service and three by prison officers. In the course of making selections for these appointments thirteen applicants from among prison officers were considered. The qualifications and experience of such officers are always taken into account, but service in a women's prison is not necessarily a qualification for the very different work of matron in a Borstal institution for boys and young men.

Infant Mortality in Kensington

Mr. James Duncan asked the Minister of Health (1) if he was satisfied that the steps taken to deal with infant mortality in Kensington were adequate, and (2) what steps were being taken by the Kensington borough council to reduce the infant death-rate in North Kensington.—Sir Hilton Young replied: I am informed that the subject of infant mortality in Kensington has at all times received careful attention and study by the borough council and has recently been the subject of a special investigation by them. The council have provided a comprehensive maternity and child welfare service, which

NOTES, COMMENTS, AND ABSTRACTS

NUTRITION

AN AGREED STATEMENT ON BASIC REQUIREMENTS

In its report on the minimum cost of a sufficient diet, issued last November, the British Medical Association's committee on nutrition adopted a scale of calories and first-class protein which was higher than that laid down by the committee which advises the Minister of Health. The difference gave rise to comment, and the Ministry issued a statement to local authorities stating that its committee saw no reason to modify the advice it had given (see THE LANCET, Jan. 13th, 1934, p. 87). The points at issue have since been discussed by a conference of representatives of the two committees,[1] and the following report has now been issued by the Ministry, signed by Sir Gowland Hopkins (chairman), Prof. Cathcart, Prof. Cowell, Dr. Crowden, Prof. Mellanby, and Prof. Mottram.

The Report

The business before the conference was to consider whether any important differences existed between the recommendations of the Ministry's Committee, as stated in their Memorandum "The Criticism and Improvement of Diets," and those of the British Medical Association's Committee, as outlined in their special Report on Nutrition, and if so, to determine the significance of such differences.

After examination of the position it became clear to the conference that the divergencies were more a matter of misunderstanding and misinterpretation than of actual fact.

In the first place it is desirable for a proper understanding of the position that the nature and objectives of the two Committees should be made clear.

The Ministry's Committee is a permanent advisory body first appointed in January, 1931, by the then Minister of Health, Mr. Arthur Greenwood. The duties of the Committee are to advise the Minister on the practical application of modern advances in knowledge of nutrition. The Committee consists of workers with a special knowledge of nutrition, who, as occasion demands, place their scientific knowledge at the disposal of the Minister and his staff to assist him and his department in administrative action. It does not possess any authority, nor does it attempt to give advice on economic matters. In their memorandum "The Criticism and Improvement of Diets," the Committee recommended 3000 calories and 37 grammes of first-class protein, or thereabouts, as adequate to supply the needs of the average "man" of the entire population of the country. *These recommendations were intended as a rough guide to medical officers of health so as to assist them in placing the nutrition of communities and institutions under their charge on a proper basis.* These values, being statistical averages, were meant to be applied to whole communities and not to individuals or even to single families. It is in this respect that the purpose of their recommendations differed most markedly from those published by the British Medical Association's Committee.

It is necessary also to point out that the responsibility for these and other recommendations made by the Advisory Committee belongs to the members of the Committee entirely and not to the Ministry of Health; and further, that in the above-quoted memorandum no recommendations of an economic nature were put forward.

The British Medical Association's Committee, on the other hand, is not a permanent body, but was a special ad hoc committee assembled for a specific purpose, "to determine the minimum weekly expenditure on foodstuffs which must be incurred by families of varying size if health and working capacity are to be maintained, and to construct specimen diets."

The terms of reference thus involved a task of a financial nature, but in order to discharge this the Committee had to decide on the food allowances necessary to maintain health and working capacity. In coming to a decision they thought naturally of unemployed men and their families and bore in mind that many unemployed spend a good deal of their time working on allotments, going to and from labour exchanges and places of employment in search of work, or else in keeping themselves in good physical condition by daily exercise in training centres. And since the food requirements of the individual depend on the amount of physical exercise taken, the Committee felt justified in recommending 3400 calories and 50 grammes of first-class protein per "man equivalent" as essential to maintain the health and working capacity of a family of this type. The Committee regarded these figures as sufficient to cover a wastage of 10 per cent., but did not suggest that they should be applied to the population as a whole or even to communities or institutions. It can thus be seen that, whereas the British Medical Association's Committee confined their attention to single active families, the Ministry's Committee had in view communities of people many of whom lead comparatively inactive lives.

CALORIES

The conference considers it important to emphasise the fact that nutrition and dietetics, dealing as they do with physical and chemical changes inside the body, most of which are imperfectly understood, cannot be considered exact sciences. The calorie is merely a convenient unit for measuring the energy-content of food and the energy-output of the body. Furthermore, it must be clearly recognised that owing to individual differences in physique, personal habits, likes and dislikes, and the variations in the degree of muscular effort involved in different occupations, it is not only impossible to define, but also there does not in fact exist, any standard of food requirement which can be rigidly applied to all men alike. If such a standard were defined and universally applied, it would at once be found that, while some individuals were satisfied, others would have either too much or too little. The amount of physical work, housing conditions, clothing, climate and personal characteristics are factors influencing the need and desire for food which have to be considered when dealing with individual men.

It appears, therefore, that a workable solution of the problem of physiologically desirable dietary standards for individuals can only be found in a sliding scale of calorie needs based on age, individual physique, occupation, and habits. On the other hand, in the case of mass calculations of the total food requirements of the population as a whole, where the question of distribution to individuals or purchasing by single families does not arise, or in the case of communal feeding, the difficulty of the standard ration being suited to the needs of each individual is largely overcome by the give and take in the food demands of the various individuals making up the community.

It is indeed a fact that, while certain limited classes of men need well above 3400 calories per day, others need less than 3000, and therefore the sliding scale of calorie needs now put forward by the conference has been constructed in the hope that it may provide authorities with a satisfactory working basis on which to determine the needs of individual men and families of varying composition. Such a sliding scale should not, however, be interpreted in too rigid a sense, for the unique nature of each individual's food requirements cannot be too strongly emphasised. The sliding scale adopted by the conference is shown below :—

---

[1] The following members took part in the proceedings: Prof. E. P. Cathcart, M.D., F.R.S., Sir F. G. Hopkins, F.R.C.P., P.R.S., Prof. E. Mellanby, F.R.C.P., F.R.S. (representing the Minister's Advisory Committee); Prof. S. J. Cowell, M.R.C.P., Dr. G. P. Crowden, Prof. V. H. Mottram (representing the B.M.A. Committee); Dr. G. C. Anderson, and Dr. H. E. Magee (joint secretaries). The report is issued by the Ministry of Health and is obtainable from H.M. Stationery Office, price 2*d*.

SLIDING SCALE OF CALORIE REQUIREMENTS PER DAY

Individuals	Calories gross.	Individuals	Calories gross.
Man : heavy work	3400–4000	Child : 12–14	2800–3000
,, moderate work	3000–3400	,, 10–12	2300–2800
,, light work ..	2600–3000	,, 8–10	2000–2300
Woman : active work	2800–3000	,, 6–8	1700–2000
,, housewife	2600–2800	,, 3–6	1400–1700
Boy : 14–18 ..	3000–3400	,, 2–3	1100–1400
Girl : 14–18 ..	2800–3000	,, 1–2	900–1100

The conference also agrees that the all-round average requirements of the entire population or of large mixed groups of people at the present time is about 3000 calories per day. This figure can safely be employed for calculations of mass requirements, but, in the case of individuals, and single families, due regard should be paid to the sliding scale detailed above.

Of as great significance to health as calories are the proteins, minerals, and vitamins in the foodstuffs which go to build up the tissues of the body. Because of the special needs associated with the growth and development of new tissue, proteins, minerals, and vitamins are particularly important for children and expectant and nursing mothers.

PROTEINS

The general statements recited in regard to standards in respect of calorie requirements apply also to the needs of individuals, families, and communities for protein. Accumulated evidence indicates that the total daily need for protein per man unit probably lies between 80 and 100 grammes, that is, from $2^{4}/_{5}$ to $3\frac{1}{2}$ ounces. The precise amount of protein needed by any particular individual depends on physique, occupation, habits, personal tastes, and age, while climate appears also to be a factor of some importance. There is a general consensus of opinion that a certain proportion of the total protein should be in the form of first-class protein—i.e., protein of animal origin such as milk, eggs, cheese, meat, or fish. The desirable proportion of animal protein to total protein has, so far as our knowledge goes, never been exactly determined ; but we are convinced from the evidence which is available that the growing child and the expectant and nursing mother require relatively large amounts of first-class protein, much more indeed than would be arrived at by simple calculation based on their man-value equivalents.

All recent studies on the nutrition of children have shown that milk is for them a most valuable food. It is indeed the only naturally balanced food we know of, containing as it does in readily available form not only first-class protein (18·7 grammes or $\frac{5}{8}$ oz. to the pint), but also minerals, vitamins, carbohydrate, and fat. The conference therefore desires to stress the importance of this highly nutritious food for the child and the nursing and expectant mother. Both the Ministry's Committee and the Committee of the British Medical Association were mindful of these facts in regard to the special needs of the child, and both stressed the importance for children of the provision and consumption of milk in adequate quantities.

In the case of the adult the conference is of the opinion that a diet to be reasonably adequate should always contain a proportion of protein of animal origin : and that on the basis of accepted dietaries, which have stood the test of practical experience, this proportion should not be lower than one-third of the total protein consumed, and may perhaps with advantage be increased to a half.

In applying these recommendations to individuals it must be remembered that in the case of both children and adults the foregoing statements are generalisations, which may well be qualified by individual tastes and variations, and, moreover, it should be pointed out that all proteins of animal origin do not necessarily possess the same nutritional value.

NO FUNDAMENTAL DISAGREEMENT

The members of the conference deplore the exaggerated importance which has been attached to the alleged disagreement between the two committees, and wish to avail themselves of this opportunity of stating that there did not exist, nor does there exist now, any fundamental disagreement on matters of scientific fact between the two bodies.

In conclusion it may be said that it is the earnest hope of the conference that these recommendations will prove of practical value to local authorities and others, and will enable them to place the nutrition of those under their charge both individually and collectively on a sound basis, in the interests of the health, fitness, and well-being of the nation.

PHOSPHORUS AND RICKETS IN SHEEP AND LAMBS

WHILST experimental work upon mineral deficiency in laboratory animals has been carried out for many years, the study of this deficiency in farm animals has developed comparatively recently. H. Müller (1873), F. Roloff (1860), and other early German workers realised the dietetic importance of phosphorus and calcium ; their work, however, was overlooked and the subject of mineral metabolism was only reopened, on a serious scale, in the course of research work upon botulism. During experiments designed to establish the ætiology of "lamsiekte," a disease of cattle in South Africa, information rapidly accumulated regarding the influence of phosphorus upon the development and health of domestic animals. The history of the study of aphosphorosis in ruminants has been summarised[1] by Sir Arnold Theiler and Mr. H. H. Green, D.Sc. For many years it was considered that sheep, under natural conditions, did not suffer from mineral deficiency diseases ; more recently it has been found in South Africa, Northern Europe, and elsewhere, that if the phosphorus deficiency is sufficiently severe osteomalacia does occur. Sir Charles Martin and Mr. A. W. Pierce, B.Sc., in a recent publication—the first of a series[2] entitled Studies on the Phosphorus Requirements of Sheep—describe experimental work carried out in Australia. A group of four ewes and five lambs were kept for eleven months on a diet adequate in proteins and vitamins, but containing only 0·6 g. of phosphorus per day, whilst control animals received 1·6 g. of phosphorus. It was found that the deficient group became fatigued rather rapidly, but, except for one lamb which developed clinical signs of rickets, the remainder showed no obvious differences from the controls. Analysis of the experimental data brought out the following facts. The consumption of bulky food (roughage) was considerably lower per head in the deficiency group than in the control group, whilst the gain in weight was 30–40 per cent. less. Blood analysis showed a striking fall in inorganic phosphate in the deficiency group, the fall commencing early in the experiment ; the blood calcium was higher in the deficient group by the end of the experiment than in the controls. In general the foregoing findings confirm those of the South African workers. As regards wool production no appreciable difference was found in the quantity or quality of the wool from the lambs, whereas in South Africa deficiency resulted in the growth of a decreased quantity of very fine —i.e., thin fibre—wool ; the S. African experiments, however, were carried out upon pregnant and lactating ewes suffering, in consequence, from a very severe mineral drain. The bones of the lambs in the deficiency group showed, at the end of the experiment, osteoporosis and to a lesser degree osteomalacia. One lamb developed typical rickets ; a most interesting observation, for though there are a considerable number of reports of the occurrence of rickets in lambs, in comparatively few cases has the diagnosis been confirmed histologically. Also, this lamb lived under conditions very similar to nature, receiving adequate food (except phosphorus), vitamins, and sunlight, whereas most cases previously reported have been associated with an abnormal lack of sunlight.

LINES TO A G.P.

THE following lines in which neat versification blends wit and serious thought have been extracted, with thanks, from the April issue of the *St. Mary's Hospital Gazette :*

He's a general practitioner,
Sidesman and missioner,
And in addition a
First-rate physician, a
Man of decision, a
Great reconditioner.
By general admission a
Leading parishioner.

He's just a G.P.
With a minor degree,
And patients he'll see
At a very small fee.
But his slightest decree
Rules the whole family.
You can take it from me,
They daren't disagree.

He's the family adviser,
There's nobody wiser.
At birth or demise a
Successful deviser
And kind sympathiser.
Who could deny, Sir,
A gift from the sky, Sir,
To help you and I, Sir!

BOYS' CLUBS

HIS daily contact with a well-known Jewish Club—The Bernhard Baron Settlement—has given Mr. Henriques a unique opportunity for studying the personality of the young members of a large city, let loose after school and working hours in unattractive, insalubrious, and often mentally unsatisfactory surroundings. He has set out the results of his experience in a little book[1] full of interesting facts on club management, and still more interesting facts about club members, their mental attitude, aspirations, and difficulties. From the psychological point of view, the chapters on leadership, religion, and sex are the most outstanding. Perhaps in later and expanded editions more space will be given to these vital topics. But even in its present form this readable handbook ought to be in the hands of any physician whose work brings him into contact with social situations which throw a light upon neurosis and delinquency.

CONTRACEPTIVE METHODS

WE have received from Mr. Cecil C. B. Voge, Ph.D., B.Sc., F.R.S. Edin., a questionnaire directed to obtaining accurate information with regard to results of the methods employed in the use of contraceptives. Mr. Voge is, as some of our readers may know, the author of a book on the chemistry and physics of contraceptives in which the action of pure chemicals on the life of the spermatozoa is reviewed and in which much information with regard to proprietary contraceptive compounds is supplied. He has recently formed a museum in the department of public health of the London School of Hygiene and Tropical Medicine (vide THE LANCET, Jan. 21st, 1933) with the object of dealing with various aspects of a multi-sided subject.

The questionnaire on contraception consists of two forms, one for the medical profession and the other for lay persons. In form I. these pertinent questions are asked: the age on marriage of each patient, the number of pregnancies, miscarriages, abortions, or stillbirths, if a contraceptive method has been used and abandoned, and if abandoned, why? The practitioner is asked to state also the particular methods which he has recommended and which of them he prefers. In form II. the age on marriage of the subject is asked, the number of children living or dead, and the number of miscarriages and stillbirths, and details with regard to sexual life are invited; and it is inquired whether the employment of any birth control method has prevented pregnancy or borne any relation to sex satisfaction. If the reasons for failure of the method, the trade name of which should be supplied, can be ascertained, they should be given.

The forms can be obtained from "Consulting Chemist" 2, Gray's Inn-road, London, W.C.

"CHINESE MEDICINE."—Messrs. H. K. Lewis inform us that the price of this book, by Dr. W. R. Morse, reviewed in our issue of May 5th (p. 962), is 7*s.* 6*d.*

Messrs. EDWARD ARNOLD & Co. write: "It has been pointed out to us by Dr. William Brown that certain phrases in our advertisements of the third edition of his book, 'Psychology and Psychotherapy' might be construed as being contrary to the accepted principles of medical ethics. In view of this we wish to make it clear that the responsibility for these advertisements rests entirely with us, and not with the author, who did not know of their contents until they were published. Future advertisements will be suitably modified."

LONDON HOSPITAL RESEARCHES.—Reprints of 31 of the papers published from the London Hospital last year are collected in a volume issued by Messrs. H. K. Lewis at 7*s.* 6*d.* Four are concerned with filtrable viruses (psittacosis and zoster), a subject in which investigation is actively pursued in the Freedom research laboratory by Dr. S. P. Bedson and his associates. Renal function in various of its aspects is considered in three papers, two of them from the medical unit, of which Prof. Arthur Ellis is director. Dr. Paul Fildes, F.R.S., and co-workers contribute four papers on the nutrition of bacteria; Dr. William Evans and Dr. Clifford Hoyle have reprints of two of their studies on the therapeutics of angina pectoris; and Dr. Hoyle is also author of three other papers, two of them on hypertension. Besides nine papers reproduced from our own columns the volume contains also Dr. Eric Skipper's review of diabetes mellitus in pregnancy, two of Dr. Dorothy Russell's contributions to the histology of cerebral tumours, and Mr. R. K. Debenham's analysis of 742 cases of hæmaturia.

Births, Marriages, and Deaths

BIRTHS

BARLOW.—On May 10th, at Welbeck-street, the wife of Surgeon-Commander N. A. H. Barlow, R.N., of a daughter.

CRAIG.—On May 4th, the wife of Dr. Nicholas Craig, Cheadle Hulme, Cheshire, of a son.

DYSON.—On May 10th, at St. Mawes, Cornwall, the wife of Malcolm Dyson, M.D., of a daughter.

FIDDIAN-GREEN.—On April 17th, at Matatiele, East Griqualand, South Africa, the wife of Dr. W. B. Fiddian-Green, of a son.

MACDONALD.—On May 7th, at Grosvenor-street, Edinburgh, the wife of James F. MacDonald, M.B., F.R.C.S.E., Northern Rhodesia, of a daughter.

SCHNEIDER.—On March 31st, at Southampton, to Dorothy, wife of Dr. J. E. Schneider—a daughter.

DEATHS

GREENE.—On May 12th, at Stratford-on-Avon, R. L. W. Greene, L.R.C.S., L.R.C.P., J.P., aged 81 years.

HALLEY.—On May 13th, at Fulham-road, S.W., William Halley, M.R.C.S., L.R.C.P., aged 71 years.

KIDD.—On May 12th, at Bransbury Mill, Barton Stacey, Francis Seymour (Frank) Kidd, Surgeon of Harley-street, W.

OGILVY.—On May 13th, at Long Grove House, Epsom, David Ogilvy, M.D.

PATERSON.—On May 11th, at Aigburth Hall-avenue, Liverpool, William Brogdon Paterson, M.B., C.M. Edin.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THE CHILDHOOD TYPE OF TUBERCULOSIS *

By Leonard G. Parsons, M.D., F.R.C.P. Lond.

PHYSICIAN TO THE CHILDREN'S AND GENERAL HOSPITALS, BIRMINGHAM; PROFESSOR OF DISEASES OF CHILDREN IN THE UNIVERSITY OF BIRMINGHAM

The childhood type of tuberculosis has been defined as "the diffuse and focal lesions in the lungs and adjacent tracheo-bronchial glands that result from the first infection of the pulmonary tissues by the tubercle bacillus," and in dealing with some of its aspects I hope to explain the apparent paradox that tuberculosis in early childhood may be both a benign and a fatal infection.

For many years it was held as an axiom in medicine that pulmonary tuberculosis in infants and young children was usually a fatal disease; in infancy, because of the rapidity of extension of caseous pneumonia and the liability to miliary tuberculosis; in childhood, because the disease is not limited to a portion of the lung by fibrosis—a process which is so characteristic of the adult type of tuberculosis—although with increasing age the child gradually develops the capacity to achieve this end. Therefore, at the one extreme of childhood there was the danger of rapidly spreading caseous broncho-pneumonia and miliary tuberculosis; at the other, the approach to the adult form of chronic pulmonary tuberculosis, and in the intermediate period the tendency to miliary tuberculosis and caseous broncho-pneumonia becoming progressively less marked. In this intermediate period the disease was regarded so seriously that, having made the diagnosis of pulmonary tuberculosis, the child's expectation of life could be measured roughly as one month for every year of its age—i.e., a child of six years had an expectation of life of only six months. This was the reason given to explain the fact that pulmonary tuberculosis is only a rare cause of chronic illness in childhood, and quite uncommon in children attending school.

Mode of Infection

The view that pulmonary tuberculosis was usually the result of inhalation of tubercle bacilli was widely held until some 25 years ago. About that time the importance of tuberculous milk in producing disease was realised, and the inhalation theory was contested so effectively by Calmette and others that in 1910 it was accepted that "air infection probably means that the bacillus enters through the mucous membrane of the throat or alimentary tract. Direct infection of the lungs is 'negligible'" (Cautley [1]). This "alimentary" view was based upon the important parts played in the tuberculosis of childhood by: first, the bovine infection of milk; secondly, the lymphatic glands. The disease appeared to arise in the lymph glands, since enlarged and caseous mesenteric glands were frequently found at autopsy or at operation and, which was even more important from the standpoint of this theory, caseous bronchial glands without any obvious lesion in the lungs were by no means an uncommon occurrence in autopsies. Infection of the bronchial glands and lungs via the alimentary tract and lymphatic system has been demonstrated experimentally, although a much larger dose of tubercle bacilli is required for infection by this route than by the air-passages. Anyone who has witnessed a post-mortem of, say, neuroblastoma of the suprarenals, will realise that the possibility of infection by this route cannot be denied; nevertheless, we can now say that the alimentary view of tuberculous infection of the bronchial glands is absolutely untenable, although infection of the lungs with bovine tubercle bacilli via the blood stream, which in its turn has been infected from an abdominal lesion, is a possibility, and actually does sometimes occur. Thus Blacklock [2] found the bovine bacillus in three instances in a series of 108 children under twelve years of age who suffered from thoracic tuberculosis.

The observations which eventually killed the alimentary theory were those published by Ghon in 1912, just at the time when the alimentary view was gaining so many adherents. Many years ago Cohnheim enunciated the law that the portal of entry of the tubercle bacillus was indicated by the fact that the lymph glands draining that area became infected, and it is now held that wherever tubercle bacilli first gain an entrance into the body a triad of changes takes place to which the name "primary complex" was given by Ranke; first, the primary tuberculous focus at the place where the bacilli lodge; secondly, a tuberculous lymphangitis spreading from the primary focus to the lymph glands draining that area; thirdly, inflammation and a tendency to caseation of these glands. Ghon showed that the primary lesion from which the bronchial glands became infected was situated in the lung, and that this primary focus was so small as frequently to be overlooked. In other words the infection was air-borne, and in his view 95 per cent. of tuberculosis occurred in this way. Such a conception explains the fact that tuberculous mediastinal glands may be found at autopsy without clinical or even obvious post-mortem signs of pulmonary tuberculosis. Ghon's work was unknown, or at any rate unaccepted, for many years; indeed, its importance has only been realised in recent times.

Epituberculosis

In the light of the doctrine that tuberculosis in early life is so fatal that, according to a leading British text-book of Children's Diseases published in 1929, "in the first year of life probably nearly all infected children die," [4] it is difficult to understand why the tuberculous process in the lung is ever limited to a Ghon's tubercle, and why the disease ever becomes arrested, but it is quite impossible to comprehend such a case as the following:

A male child suffered from cough and bronchitis from the fourth month of life, and at the age of 13 months was admitted to hospital. He remained in hospital 13 months. His general condition during this time was excellent, he put on 10 lb. in weight and on discharge was over the normal weight for his age. There was no dyspnœa and very little cough. He had both clinical and X ray evidence of consolidation of the upper part of the left lung, the extent of which was surprising in view of the boy's excellent condition. The lung was needled twice but no fluid obtained. The Mantoux intradermal test gave a markedly positive reaction. The sputum was examined for tubercle bacilli on two occasions, and the stools on no fewer than 13 occasions, but always with negative results. After he had been in hospital 10 months his fasting gastric juice was injected into a guinea-pig, and the animal subsequently developed tuberculosis. Two months later this procedure was repeated with a similar result. Considering that his general condition was so good, he was discharged from hospital when he was two

---

* An address delivered to the Sheffield Medico-Chirurgical Society.

years and two months old. Eighteen months later—that is, two and a half years after first being observed—a radiogram of his chest was reported as normal.

I submit that this case was proved to be a tuberculous infection of the lung of benign character, since during the whole time the boy was in hospital he was practically free from symptoms and made a complete recovery. I cannot see that Findlay[5] has any ground for the statement that in cases of this character

> "tubercle bacilli are never detected in the sputum, so that there is always the possibility, in fact the strong probability, that the condition is not tuberculous at all. . . . In our experience lesions conforming to the above description have been slowly resolving simple pneumonia, which has come under observation after the crisis."

It is quite true that the shadow in the radiogram may closely resemble that cast by an alveolar pneumonia, but for myself I cannot conceive of such a pneumonic condition lasting for a period of months, or years, and then clearing without showing any clinical or radiographic signs of fibrosis.

The well-known French physician—Grancher—in the closing years of the nineteenth century showed that exudates in a tuberculous lung sometimes completely cleared up—a condition to which he gave the name spleno-pneumonia—but interest in this subject was not aroused until in 1920 and 1921 Eliasberg and Neuland[6] reported the occurrence, and 6 to 18 months later the complete resolution of lobar exudates in one or more lobes in infants who gave a markedly positive tuberculin test. Some of these infants had tuberculous lesions in glands and bones, but in all cases the pulmonary infiltrations found came as a surprise because of their extent and the good general condition of the child. The case I have detailed corresponds in every way with their description, except that positive evidence was obtained that tubercle bacilli were present in the stomach washing. They called these lesions "epituberculosis," regarding them as non-specific, non-tuberculous inflammations occurring around a tuberculous focus. This view was based upon the commonly accepted theory of the lethal nature of pulmonary tuberculosis in young infants, the argument running thus: such a degree of exudate if it were tuberculous must have an acute onset, must render the patient very ill, must go on to caseation, and must eventually cause death. Therefore, because these patients recovered the condition could not be tuberculous. "A generation born to a tradition of pessimism in the prognosis of extensive pulmonary tuberculosis confronted with the clinical facts of recovery, prefers to dispute the specificity of the regressive lesions" (Reichle[7]). A little later—namely, in 1923—Langer[8] reported the case of a child who had an exudate in the left upper lobe which in course of time completely disappeared but reappeared after the injection of 0·1 mg. of tuberculin. The recurrence of the shadow was accompanied by dullness and diminished breath sounds, all of which (including the shadow) cleared up within 14 days. Langer regarded this as proving first, that the original lesion was tuberculous and, secondly, that the change in the lung produced by the injection of tuberculin was a specific one. The conception of epituberculosis was therefore altered, and it was regarded as an allergic phenomenon, a non-tuberculous inflammation occurring round a tuberculous focus, in fact around a Ghon's tubercle; a conception which makes epituberculosis strictly comparable with the inflammation, œdema, and redness which surround the injected tuberculin in a positive Mantoux reaction. There is, however, this difference: the shadow in the lung produced by tuberculin, and the area of redness round the Mantoux reaction soon disappear, whereas the shadow cast by epituberculosis remains for months or even years. The explanation of the transient character of the inflammatory changes in a positive Mantoux reaction probably lies in the fact that the amount of antigen is only small and soon absorbed.

A BENIGN FORM OF PULMONARY TUBERCULOSIS

My introduction to epituberculosis was the result of a visit to Prof. E. Gorter's clinic at Leyden in 1926, when he described a typical instance in a girl of 3 years in whom an exploration of the lung, in the region of the interlobar (upper and middle lobes) fissure, resulted in the withdrawal of a small amount of material in the needle, which on examination was found to contain tubercle bacilli. The interpretation of this finding was that the needle had entered the Ghon's tubercle. Eighteen months later, although the lung condition had shown considerable improvement, the child died from tuberculous meningitis and, on the result of an autopsy, he came to the conclusion that from a small caseous focus which was found under the pleura at the junction of the middle and upper lobe there had spread what he described as a "collateral inflammation over the largest part of the upper lobe."[9] Attending the out-patient department of the Birmingham Children's Hospital is a child who has the typical radiographic appearances of epituberculosis, which are slowly clearing up and from whom, over a year ago, tubercle bacilli were obtained by needling the epituberculous area. The odds against the contents of a small Ghon's tubercle, the site of which there is no indication, being tapped in two children, must be very great, and these findings, together with those of Langer, are very suggestive that epituberculosis is a true tuberculous process. Moreover, even more convincing evidence has been obtained by Spence[10] in the following case:—

> A boy, aged 7 months, old had typical signs of epituberculosis of the upper two-thirds of the left lung, which was explored when the child was 9 months old, tubercle bacilli being found in the needle contents. Four weeks later a second exploration was performed with the same result. On the first occasion the needle was inserted into the third inter-space in the axillary line, and on the second occasion it was inserted in the same space but in front in the mid-clavicular line and directed medially, so that the point of contact with the lung should be as far as possible removed from the site of the previous puncture. The child made a complete recovery, after an illness lasting some months, and the radiogram became normal.

We must agree with Spence that these findings placed the tuberculous nature of the process beyond doubt, and suggest that the whole lesion in epituberculosis is a tuberculous process. Spence indeed regarded the condition as a caseous tuberculous process, but I find it difficult to believe that the whole of the area could have been caseous and yet completely resolve.

The possibility that some caseous areas may heal completely must be admitted because Gardner[11] has shown by animal experiments that, by a process of resolution, caseation can be absorbed without leaving any trace of the original lesion. Further, Reichle[7] has found areas of caseous pneumonia showing giant cell formation contiguous with areas of infiltration which macroscopically were indistinguishable from ordinary broncho-pneumonia, and which microscopically showed simple inflammatory changes with numerous tubercle bacilli; in other words, the tubercle bacillus can produce a change which is in all respects similar to that produced by other organisms and from which it is universally recognised that complete resolution may occur. In a child under our care who died from epituberculosis both these changes were found, although tubercle bacilli were not demonstrated in the areas of pulmonary catarrh.

This child, a girl, whose mother had advanced pulmonary tuberculosis, was admitted to hospital for wasting at the age of 14 months. Tuberculin skin tests were positive and examination of the chest revealed only scattered rhonchi and a few râles. Three months after admission she had a rise of temperature to 102°–104° F., and there were many râles and rhonchi scattered over the chest, and 10 days later dullness over the right upper lobe was elicited. Prior to her death some four months later, this lobe was needled seven times, and on one occasion only a small amount of blood-stained fluid was removed, which did not show tubercle bacilli. The fæces were twice and the gastric juice once examined for tubercle bacilli, but none was found. Occasionally there were ronchi and râles to be heard over other parts of the lungs. At the autopsy the right upper lobe was completely consolidated, showed many miliary tubercles and one or two small cavities. Miliary tubercles were scattered over both lungs. The mediastinal glands were caseous and one of these had ruptured into the right bronchus, the branches proceeding to the middle and lower lobes being almost occluded with caseous material. Microscopically, in the upper lobe, contiguous with areas showing caseation, endothelial cell infiltration with giant cell formation, and numerous tubercle bacilli, were found small areas of pulmonary catarrh in which the alveoli contained many large mononuclear cells and thickened interlobar septa.

Epituberculosis does not occur until the tissues have become allergic, but from the evidence which I have submitted it appears obvious that it should be regarded as a benign form of tuberculosis and not a pure allergic reaction; although for convenience I shall continue to refer to it as epituberculosis. It is difficult to assess the relative importance in epituberculosis of allergy and the presence of tubercle bacilli in the affected area, but it may be that the persistence of the shadow in the radiogram is due to the actual presence of the bacilli in the area whereas the more evanescent character of the exudates which follow injection of tuberculin are due to tissue allergy only.

Children suffering from epituberculosis react positively to tuberculin tests and frequently are known to have been in contact with adults suffering from pulmonary tuberculosis. The condition is usually characterised by mild constitutional symptoms such as slight fever, some cough, and loss of weight; nevertheless, all symptoms may be completely absent, and the child appear active, healthy, and putting on weight. On X ray examination there is found an extensive area of pulmonary consolidation occupying a great part, or the whole of one or more lobes, and sharply delineated. Frequently also there are only scanty physical signs, but there may be dullness and tubular breathing over this area. As may be gathered, epituberculosis is usually only discovered by radiographic examination, the results of which are strikingly at variance with the symptoms, and often with the physical signs. The course, which is every chronic, lasting months or years, usually ends in a complete recovery. The shadow in the radiogram gradually clears from the periphery, and as it does so a calcified nodule—the calcified Ghon's tubercle—may become obvious, or enlarged and calcified hilus glands may be recognised. Sometimes also there is left a well-marked thickening of the interlobar septum. This thickening is the result of a pleurisy, perhaps associated with the epituberculous process, but more probably produced by the primary tubercle of Ghon, which is frequently situated directly under the pleura and may lead to extensive involvement of it. Although the Ghon's tubercle may not be seen in the radiogram until the shadow of epituberculosis has disappeared, it is highly improbable that it is formed as the result of epituberculosis, because until a degree of allergy has been produced the tissue reaction producing such a lesion as epituberculosis cannot occur.

If the infecting dose of tubercle bacilli is not too large, the initial infection of the lung not only in childhood but at all ages may not produce any symptoms and is quite likely to pass unnoticed.[12][13] At this period, which has been called the primary tuberculous state, the tissue reaction is of the proliferative—epithelioid—type. If the lesion is a small one, complete recovery is possible either by absorption or rapid calcification. The lesion may, however, persist, leading to infection of the bronchial glands and occasionally—particularly if the infecting dose is a massive one—to a rapid generalisation of the disease. A few weeks after the original infection, except in cases of rapid generalisation, a high degree of allergy develops and the tuberculin tests become positive; at this stage if the original primary stage fails to heal, or if a further infection with tubercle bacilli takes place, a different type of tissue reaction—the exudative reaction—occurs. This is characterised by a rapid outpouring of serum and leucocytes, and may be sufficiently extensive to produce a shadow in the radiogram; thus a child who is known to have been exposed to infection develops a positive tuberculin reaction and shows enlargement of bronchial glands or shadows in the lung usually between the fourth and seventh week after exposure (Holt and McIntosh[14]). In this the secondary tuberculous state the symptoms are those already described as occurring in epituberculosis, and such manifestations as phlyctenular conjunctivitis, erythema nodosum, and pleurisy may also be encountered. Earlier in this address the childhood type of tuberculosis was defined as being the diffuse and focal lesions in the lungs and adjacent tracheo-bronchial glands, which result from the first infection of the pulmonary tissues by the tubercle bacillus; a definition which it is therefore quite obvious covers epituberculosis.

Ghon's Tubercle

The actual results produced by this primary infection of the lungs depend almost certainly upon the size of the infecting dose. With minimal doses of tubercle bacilli it is perhaps possible for complete recovery to occur without involvement of the bronchial glands. In mild degrees of infection a Ghon's tubercle probably develops with involvement of the bronchial glands, and possibly the latter may occur even without the formation of the primary tubercle. If the infection is rather more severe a definite Ghon's tubercle is formed, the glands become infected, and after a few weeks, when a degree of allergy has developed, a severe inflammation develops around the primary focus—a perifocal pneumonia—which if it is of any extent produces the phenomena of epituberculosis. This eventually clears, and even the Ghon's tubercle may heal. A pleural effusion may occur, due to an associated pleurisy. If the infection is of an even greater degree of severity the perifocal pneumonia may progress to necrosis caseation, or cavity formation. If not too extensive these lesions may eventually heal by fibrosis or calcification, but although, on the basis of radiographic examination, healing after cavity formation has been reported by Gerstenberger and Burghans[15] and others, in my opinion this is extremely improbable and the cases reported are not beyond criticism. If the primary infection is overwhelming in character a massive caseous pneumonia with cavitation may occur.

From the Ghon's focus or the caseous lung or bronchial glands the blood may become infected and either a miliary tuberculosis result or tuberculous lesions develop elsewhere, depending on the degree of infection of the blood. Sometimes at autopsy miliary tuberculosis is found with only a minute Ghon's focus and not very large caseous bronchial glands, suggesting that the child had not put up any fight, and blood infection and generalisation had occurred shortly after the primary infection. It is usually assumed that bone and joint tuberculosis in children is chiefly due to the bovine bacillus, but Griffith's [16] statistics show that in England in children under five, almost three-quarters, and in children over five, more than four-fifths, of the cases are due to human tubercle bacilli: in Scotland, on the other hand, these figures were respectively two-fifths and three-fifths—i.e., bovine infection predominates.

The Ghon's tubercle varies in size from that of a millet seed to that of a greengage plum. In one-third of the cases in his series Ghon found the lesion to be the size of a pea. It is situated at the periphery of the lung parenchyma, and in 90 per cent. of cases is directly subpleural, the organisms having lodged in the smallest bronchioles. Caseation, and sometimes in the largest foci cavitation, occurs; in smaller ones there may be a degree of healing as shown by attempts at capsulisation and even calcification. Adhesive pleurisy is also present in quite half the cases. The small Ghon's tubercle may be difficult to find and require a diligent search; indeed, it is often better to harden the lung in some fixing fluid before it is cut. Ghon himself frequently had great difficulty in finding the primary focus, and often missed it after hours of searching, "only to find it at a subsequent time and on further tireless examination." Sometimes there is more than one focus and Ghon found this in 16 per cent. of his cases. The distribution according to lobes of the primary focus in Ghon's series, and as judged radiographically by Stoloff [17] in Vienna, is shown in the accompanying table (Table I.).

TABLE I

		Ghon.	Stoloff.
Right lung	Upper lobe	72	118
	Middle lobe	19	69
	Lower lobe	48	167
Left lung	Upper lobe	59	71
	Lower lobe	44	99

Before leaving this aspect of the tuberculosis of childhood, I wish to make it quite clear that resolving shadows in the lungs of children suffering from pulmonary tuberculosis or of those showing positive skin tests may be due to at least two other causes—namely, pneumonia and atelectasis. The differentiation between epituberculosis and pneumonia has already been given, and it may be distinguished from atelectasis by the following features. The shadow of epituberculosis usually occurs in an area which is not involved by atelectasis—for instance, in the central area of the lung. In atelectasis the radiographic appearances differ from epituberculosis in that the atelectatic area is smaller in size and retracted towards the hilum, the heart and superior mediastinum are dislocated, and there is elevation of the diaphragm on the affected side. The shadow of epituberculosis clears slowly from the periphery, a form of clearing which would not occur in atelectasis. Atelectasis may occur from pressure of enlarged glands on a big bronchus, and Stoloff [18] has reported the occurrence of massive collapse of the lung as the result of a primary tuberculous complex, but in this case the lung expanded again within a period of four days. Again, Morlock and Scott Pinchin [19] have recently described an instance of atelectasis of the right upper lobe in a boy aged fourteen years, which gave a radiogram like epituberculosis and which disappeared after bronchoscopy. By bronchoscopy a tumour was seen passing into the lumen of the right bronchus, part of which was removed and showed typical tuberculous granulation tissue. Two weeks later the shadow reappeared, and three weeks later again the shadow once more was absent. In these respects the shadow differed from that seen in epituberculosis, the characteristic of which is its persistence for a long period.

Results of Reinfection

To complete the survey of the natural history of pulmonary tuberculosis in childhood the effect of reinfection must be considered. Reinfection may take place from without—a fresh infection—or from within. Auto-reinfection may occur in several ways: (1) by a direct spread from the root glands; (2) by dissemination in the blood stream from a tuberculous focus producing miliary or larger conglomerate lesions; (3) by the erosion of bronchus by a caseous gland producing massive infection of the area it supplies, with widespread dissemination by the bronchi to other parts of the lung and also to the opposite lung. It is clear that if infection occurs by either of the two latter methods a fatal result is certain should miliary tuberculosis develop, and almost certain otherwise. The prognosis when reinfection by extension from hilar glands or from without depends on the power of the child to localise the lesion. The older the child, the more likely is localisation to occur and chronic tuberculosis of the adult type to develop. It is, therefore, obvious that the child has to be under observation for some time before a definite prognosis can be given; nevertheless, the condition is always serious, and the younger the child the more likely is the disease to progress rapidly to a fatal termination either by extension throughout the lung or as the result of miliary tuberculosis. When this power of localisation has been evolved the condition has been called the "tertiary tuberculous state" and is due to the development of a degree of immunity as a result of recovery from either the primary or the secondary state. The development of hypersensitiveness has nothing to do with immunity, indeed Rich [20] has shown that active immunity can be produced without the development of allergy; further, Sabin [21] having produced in animals a high degree of tissue allergy to tuberculo-protein by sensitising them with the purified protein of tuberculin, injected tubercle bacilli into their lungs and found that they were more, not less, susceptible to infection—a state of affairs exactly comparable with reinfection in the young child.

From this review it is therefore, I think, proved that tuberculosis of the childhood type is in some degree very frequent, and, particularly after the period of infancy has been passed, is probably often benign in character. Various estimates, such as 50 to 100 per cent., have been formed as to its mortality in infancy, but even the lower figure is probably too high. The statement has also been made that in the second and third year infection is very common, but symptoms of the disease rare. It is probable that even in infancy benign cases do occur, but massive infections are more likely in their period than in later life, and hence the greater mortality. In view of the frequency of these benign infections are we to fold our hands and say that nothing remains to be done except to try to prevent reinfection? God forbid. This benign disease may be fraught with the most serious consequences—namely, tuberculous meningitis—and it is to this phase of the problem that I would now direct attention.

Tuberculous Meningitis

It may be argued that tuberculous meningitis, although always fatal, is not really a menace worthy of consideration because the total number of cases is small. I want, however, to make it clear that the condition is by no means rare. In the Birmingham Children's Hospital, from Jan. 1st, 1932, until Sept. 30th, 1933, a period of 21 months, there have been no fewer than 60 cases of tuberculous meningitis; 33 of these having occurred in the first 9 months of the year 1933. The remarks that follow apply to the Birmingham area, since there is evidence to show that bovine infection is more frequent in Scotland, although it should also be remembered that in other countries infection with the human bacillus plays an even greater part than in England.

Through the kindness of my colleague R. J. Gittins, pathologist to the Children's Hospital, I am able to quote the results of the post-mortem examinations of 671 children under 12 years of age. These autopsies were performed in a period of less than 3 years, and out of that number in 100 cases death was due to tuberculosis, chiefly tuberculous meningitis. The distribution of the lesions found in these cases is shown in Table II. In the earlier autopsies an intensive search for Ghon's tubercle was not carried out, otherwise the percentages under this head would have been higher, and they are considerably higher in autopsies carried out during the last year. For the purpose of comparison, the number of fatal cases of clinical broncho-pneumonia have also been calculated, and over a rather longer period of time these form an almost identical percentage of autopsies. In our hospital records, therefore, nearly one-third of all deaths are due to tuberculosis and pneumonia, and these rank equal as the two most killing diseases of infancy and childhood.

TABLE II.—*Fatal Tuberculosis in Childhood*

In a series of 671 autopsies tuberculosis was the cause of death in 100 (14·9 per cent.). The most advanced lesions in these cases were situated as follows:—

Tracheo-bronchial glands	71
Mesenteric glands	18
Cervical glands	1
Doubtful	6
Caseating glands not found ..	4

Seventy-one cases were examined for Ghon's tubercle and this was present in 49 (70 per cent.): right lung, 28; left lung, 21.

Ten children (1·5 per cent.) who died from other conditions showed tuberculous lesions at autopsy.

Another of my colleagues, A. V. Neale, has investigated the histories of 300 children under 12 years of age, who died from tuberculosis in the Birmingham Children's Hospital and a small general hospital in the same area during the years 1920–1933. In 68 of the children it was known at the time of their admission to hospital that they had been in contact with adults suffering from open pulmonary tuberculosis, and of these children 63 had primary thoracic and only two primary abdominal lesions. In three instances the infection appeared to be generalised from the onset. Through the kindness of the local public health authority visits were paid to the homes of 47 of the children in whom a history of contact could not be obtained at the time of their admission to hospital, with the result that open tuberculosis was found in adults—in most instances the father—who had access to 22 of these children. Two hundred and four of the children were under the age of 3 years, and 66 occurred in infants at the breast. Of these infants 23 were known to have been in contact with an adult suffering from open pulmonary tuberculosis. The infecting source was usually one of the parents, and, oddly enough, even in these breast-fed children, the father (13 cases) was more frequently the culprit. The reason for this is probably that a mother suffering from open pulmonary tuberculosis is rarely able to bear the strain of lactation; subsidiary causes may be the facts that women usually swallow their sputum and that fathers in the lower classes not infrequently are guilty of promiscuous expectoration.

MENINGITIS

These investigations showed that the youngest member of the family, especially if an infant, was the most likely to be infected, and they clearly indicated that the problem of preventing tuberculous meningitis in infants is that of preventing their infection with the human bacilli. The focus from which the blood stream is infected with human tubercle bacilli is either the Ghon's tubercle—rarely some other focus in the lungs—or breaking down mediastinal glands. Bovine infection cannot by any means be ruled out as a source of meningitis, because Griffith [16] has shown that bovine tubercle bacilli were found in the meningitis of more than one-third of a series of 52 children under the age of 14 living in England who died from tuberculous meningitis.

ITS PREVENTION

The prevention of tuberculous meningitis of bovine origin is a comparatively easy matter, and can be achieved by the furnishing of a safe milk-supply, a condition of affairs which would eliminate primary abdominal tuberculosis. According to estimates made by the Ministry of Health 7 per cent. of the milk supplied to large towns contains tubercle bacilli. The milk-supply can be rendered safe either by the production of tubercle-free milk or by destruction of the bacilli by pasteurisation, sterilisation, or drying the milk. The former is, of course, the better method, but it is the more expensive and difficult to carry out. Certified and Grade A (T.T.) milk may usually be accepted as free from tubercle bacilli, although there are certain loopholes in their production which suggest that even milk of this high standard is not always absolutely safe. Nevertheless, it is probable that an absolutely tubercle-free herd, and therefore tubercle-free milk, can be obtained if a herd of non-reactors is used for breeding purposes and cattle from outside sources are never introduced. An experiment which gives support to the preceding statement has recently been carried out for the Medical Research Council by Jordan in Ayrshire.[22] This experiment, which extended over three years, was concerned with an area nine miles square, and included about 30 herds. Each herd was divided into two groups and, when possible, the reactors were housed in separate buildings; if not, the reactors and non-reactors were housed at different ends of the barns and care taken to prevent cross-infection. They were grazed in separate fields, had separate water-supply, and infection from manure was guarded against. The non-reactors were recruited from young non-infected stock, mostly bred by the owners themselves and each herd was re-tested at six-monthly intervals. The reactors were sold in the open market. At the end of three years 20 herds were free from tuberculosis, whereas at the commencement of the experiment only eight were free.

Alternatively, tubercle bacilli can be killed by efficient pasteurisation, and in many towns in Canada and the United States, where such pasteurisation is compulsory, abdominal tuberculosis is a clinical curiosity. I have visited many pædiatric clinics in these two countries and can add my personal testimony to the truth of that statement. Furthermore, pasteurisation possibly, nay probably, provides an answer to the criticism implied in the question: Is not the ingestion of tubercle bacilli of great value in developing immunity in the child? The answer is in the affirmative, if only the dosage could be controlled, and this fact is, of course, the basis of the B C G method of immunisation of young children. Pasteurised milk almost certainly contains the toxins of the tubercle bacillus, and these probably are of value in producing immunity, whereas if certified milk is given immunity does not follow. The only real drawbacks to pasteurisation of milk are: first, that it may not be efficient; and, secondly, that as a rule butter is made and cream obtained from unpasteurised sources. Unless the milk is held at 145° to 150° F. for 30 minutes, the process is possibly more harmful than if the milk were not heated at all. It is of the greatest importance that the temperature recording apparatus, and all the other apparatus used in pasteurisation, should be absolutely reliable, and if there is any doubt about the efficiency of the process, the only safe method is to boil the milk or use a good brand of dried or condensed milk.

The elimination of tuberculous meningitis of human origin is a much more difficult task, since it consists in removal of all possibility of infection by tubercle bacilli of the human type. Many instances of tuberculous meningitis which come under my notice occur in homes in which one of the inmates has an unsuspected open pulmonary tuberculosis, or a known sufferer from that condition has failed to carry out the necessary precautions. It has been truly said that "there is more than one way of telling whether or not an adult has an open tuberculous lesion: one can find the bacilli in his sputum, or one can find the infection in his baby" (Park). The first thing in attempting to deal with this scourge is a closer examination of contacts, and especially when these are young children. In a family in which open tuberculosis is present the sufferer and the young children should be separated completely, or, if that is impossible, contact should be reduced to a minimum, and the most rigid precautions taken in regard to disposal of sputum. Careful examination of the children should be undertaken from time to time and such an examination should include the performance of the intradermal tuberculin test and a radiographic examination of the chest, both antero-posteriorly and obliquely. By this means I am sure many more cases showing exudative lesions, such as I have described, will be discovered; indeed, Armand-Delille and Lestocquoy [23] state that 50 per cent. of all pulmonary tuberculosis between the age of 5 and 10 years is of this type. I am far from convinced that this work of the examination of contacts is being carried out as efficiently as it should be, and the fault probably is not entirely that of the tuberculosis service. It is probable that none of us who has patients suffering from pulmonary tuberculosis can be entirely exonerated. Often the patient himself creates difficulties, and does with right remind us that his home is his castle and not ours. Yet, in spite of all this, I believe that more could be done in this direction by the tuberculosis service, and that there could be more coöperation between that service and the patient's doctor. I have stressed this point because contact examination is the key to the solution of this problem.

Difficult as is the problem of efficient examination of contacts, that of dealing with the children who give positive tuberculin reaction and show exudative changes in the lungs is even more difficult. There is no question that the ideal course is to remove such a child from its surroundings, or to remove the source of infection from the house, although such a counsel of perfection can rarely be carried into effect. In Toronto these children are sent to a preventorium, a branch of the children's hospital, and, of course, in France they are removed from their homes and dealt with under the Grancher system, although no child is accepted in the Grancher homes if there are any clinical or radiological signs of tuberculosis. Children who can be removed from their homes should not be sent to a sanatorium unless it is one which only admits children, and in which there is rigid isolation of children with open pulmonary tuberculosis. In spite of all that is with truth claimed for sanatoria, there is in my opinion a chance that children may contract reinfections in them if for no other reason than that patients sometimes break rules; furthermore, many sanatoria are even less fitted to care for children than general hospitals. Unfortunately there are few preventoria in England for these children, and their provision offers a great opportunity for enlightened municipal enterprise. We have attempted to deal with the fringe of the problem at our hospital by sending a few of these children to our Swiss branch at Davos for a prolonged stay, but more accommodation is urgently required. When neither the children nor the infecting adult can be removed from the home the greatest care should be taken in dealing with sputum, and the contact between the children and the adult should be reduced to a minimum. The children should receive a generous diet, rich in vitamins, and be in the open air as much as possible. They should also have regular rest periods, and if there is any degree of pyrexia should be completely in bed, if possible in the open air. Finally, every care should be taken to prevent the occurrence of respiratory catarrhs because of the liability of these catarrhs to develop into pneumonia, which is such a serious complication.

Conclusion

My survey of the childhood type of tuberculosis is now finished, and no one is more conscious than myself of its inadequacy, nevertheless I trust that I have been able to convince you that tuberculosis in infancy and early childhood is often a benign infection of frequent occurrence having a good prognosis, but that this benign infection is capable of developing into perhaps the most terrible illness of childhood, before which we are absolutely helpless; moreover, it is frequently impossible to say of any given case that this dread complication will not occur. If I have conveyed to your mind something of the horror which tuberculous meningitis inspires in me, and of the ravages of a disease which carries off far too many of the fairest and brightest children in all ranks of society, your time and mine will not have been wasted. It will not have been wasted because we shall have made up our minds to do our share to prevent its occurrence by insisting in season and out of season on the carrying out by ourselves and by others of a rigid examination of contacts, and by educating public opinion to demand a safe milk-supply, and proper provision for the isolation and treatment of infected children. To finish on a note of sadness would, however, be quite unjustified because if there is one thing above all others that recent work on tuberculosis has shown, it is that the outlook for infants and young children infected with tuberculosis is vastly better than 15 years ago we could ever have imagined possible.

OLIGURIA AND ALBUMINURIA IN BRIGHT'S DISEASE

By J. Shaw Dunn, M.D. Glasg., M.Sc. Manch.

ST. MUNGO (NOTMAN) PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW, AND PATHOLOGIST, GLASGOW ROYAL INFIRMARY

The conception of diminished urination in Bright's disease as an impaired capacity of the diseased kidneys to eliminate fluid is at once so simple and direct, and so much in accordance with many of the more easily observed clinical facts, that it has in the past been widely entertained and still forms the basis of many systems of treatment. It would appear, however, that never since Cohnheim[1] has retention of fluid by the affected organs been universally acknowledged as the primary and paramount cause of oliguria in œdematous nephritis of all kinds. While the reasons for this are numerous, and some appear very cogent, it is proposed here to deal with one only, and that is the paradoxical nature of the lesions which frequently exist in the kidneys of cases where oliguria has been a pronounced and enduring feature.

It has long been known that in many cases of subacute nephritis with obstinate œdema and oliguria the most obvious morbid changes in the kidney affect the tubular epithelium and are degenerative in nature, while the glomeruli seem little affected or even normal. As the latter are universally accepted as the eliminators of fluid, this anatomical substrate has usually been regarded as inadequate to account for diminution of the urinary flow, and for this and other reasons the cause of the oliguria in such cases has been sought in various occurrences outside the kidneys themselves. For a time a partial elucidation of this difficult problem appeared to be promised by the development of the conception of nephrosis (Munk,[2] Volhard and Fahr[3]) as a disease clinically and pathologically identifiable from subacute glomerulonephritis and possibly as a general metabolic disorder in which the kidney was only secondarily affected (Epstein,[4] Löwenthal[5]). According to this view, which has been especially promoted in this country by Bennett,[6] the oliguria of diffuse glomerulonephritis might be at any rate partly renal in origin, but in nephrosis the primary occurrence affecting distribution of fluid was œdema, and the prerenal deviation of fluid in this form resulted in the kidney having less to excrete, hence the oliguria. Apart, however, from the natural objection that this process alone could hardly be expected to maintain oliguria indefinitely after the reserves of space in the body were filled with fluid, it soon came to be recognised, partly on clinical and partly on pathological grounds, that a clean-cut separation of nephrosis from nephritis was difficult if not impossible. This has been acknowledged in the later appearance of the term "Nephritis mit nephrotischem Einschlag" (Fahr[7]) and the fact has been fully documented by Leiter,[8] who has shown that by no single feature or group of features can the most genuine nephrosis be distinguished during life from a disease which proves histologically to be subacute glomerulonephritis.

The later reactions on this impasse have been very diverse on the part of different authorities. Thus there are some, who in the main neglecting the possible significance of renal structural change in relation to the signs and symptoms, have still maintained nephrosis as an entity; while some have even considered that in nephritis of nephrotic type the now somewhat ill-defined syndrome of nephrosis is a something superimposed on the nephritis (Murphy and Warfield[9]). As representative of an opposing view may be mentioned Gainsborough[10] who has concluded that the invention of a new name has failed to embody a distinct condition and that the problem of subdivision of subacute nephritis is still unsolved.

The closer study of the renal histology in nephrotic cases which has accompanied more intensive clinical and biochemical investigations does not yet appear to have shed definite light on the situation. It has certainly been noted by experienced workers (Fahr,[11] Bell,[12] Gray[13]) that even in the cases of nephrosis, where the lesions at first sight appear most exclusively tubular, the glomeruli always show some morbid alterations. Unlike, however, the changes in glomerulonephritis, it is clear that these have frequently not been of such a kind as would occasion a diminution of blood flow, or hence, presumably of glomerular filtration, so that it has still seemed impossible to explain the very similar symptoms that may be observed in glomerulonephritis on the one hand and in nephrosis on the other by reference to a common cause in the renal lesions. In a recent article (Shaw Dunn[14]) the view was provisionally advanced that a common principle for renal retention of fluid in all œdematous oliguric nephritides might be arrived at on the basis of the modern theory of renal functionation (Cushny[15]) and that oliguria, according to that hypothesis, would most probably depend on excessive reabsorption by the renal tubules from a glomerular filtrate which might be originally normal in amount. Such an explanation would adapt itself especially readily to the peculiar phenomena of nephrosis, where sodium chloride, which is relatively abundant in the blood, is retained along with water, while urea which is scanty in the blood is readily concentrated and eliminated. A suggestion was then made as to how imbalance of reabsorption might arise in diffuse glomerulonephritis where there is clearly a limitation of reserve of the glomerular circulation, but no concrete idea could be formulated to account for a similar disturbance in nephrosis with the capillaries of the tufts uniformly patent. Since that time a further study of the glomeruli in nephrotic cases by special methods has revealed an aspect of their lesion which appears to offer an explanation in this case also, based essentially on the same principle, and originating from a vascular cause.

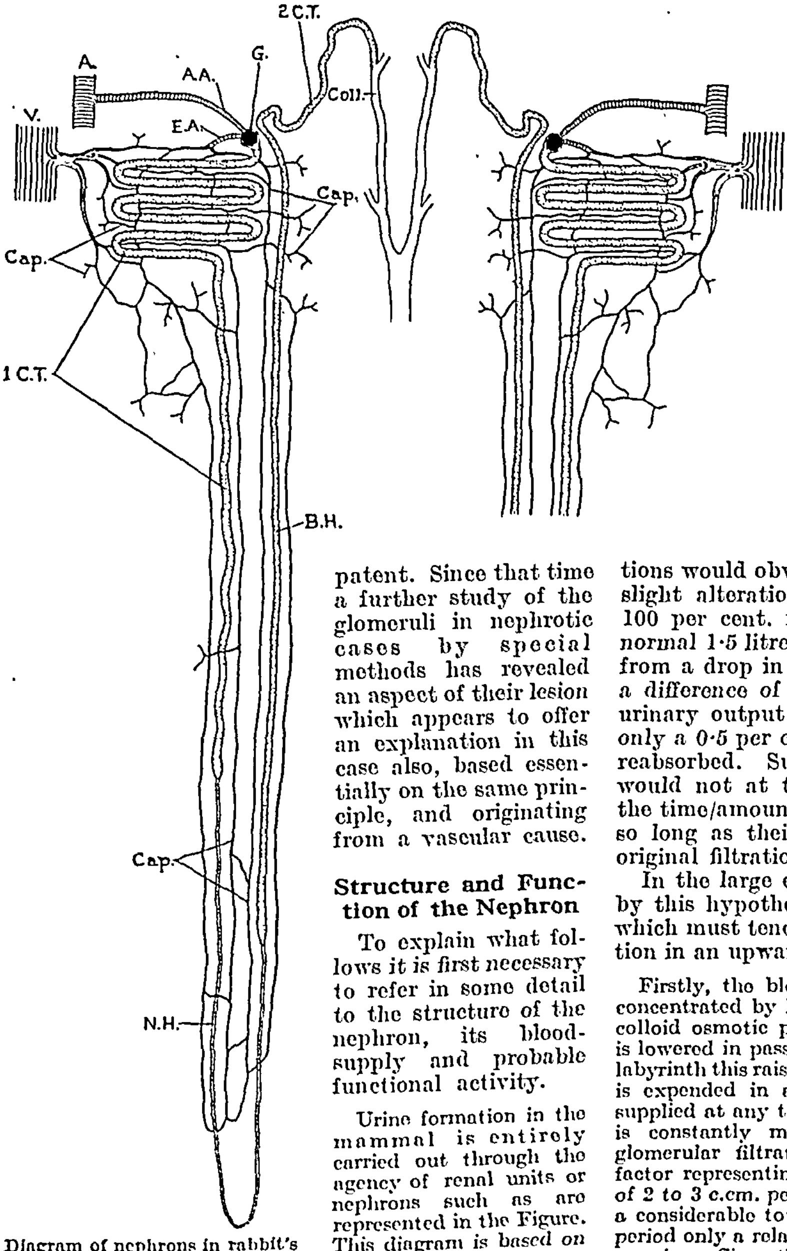

Diagram of nephrons in rabbit's kidney drawn approximately to scale from Huber's measurements of an actual structure. A. = Artery. V. = Vein. A.A., E.A. = Afferent and efferent arterioles. G. = Glomerulus. Cap. = Capillaries. 1 C.T., 2 C.T. = Convoluted tubules. N.H., B.H. = Narrow and broad limbs of Henle's loop. Coll. = Collecting tubule. (× 20.)

Structure and Function of the Nephron

To explain what follows it is *first necessary* to refer in some detail to the structure of the nephron, its blood-supply and probable functional activity.

Urine formation in the mammal is entirely carried out through the agency of renal units or nephrons such as are represented in the Figure. This diagram is *based on the drawing and measurements of an actual* average nephron from a rabbit's kidney by Huber.[16] The coiled mass of almost nude capillaries forming the glomerulus is a relatively small structure measuring in this animal 0·1 to 0·125 mm. in diameter, while the secretory part of the tubule passing from it is very long, 24 mm., and narrow, 0·05 or 0·06 mm. in external diameter: the internal diameter is variable, but even in diuresis may be only about 0·02 mm. (Brodie and Mackenzie[17]). Observing the same proportions a glomerulus 4 or 5 in. in diameter would supply a tubule of not more than an inch internal diameter and 80 ft. in length. The surface at which interchange occurs in the concentration of urine is thus relatively very large, and it is important to keep in mind that *every drop of urine that escapes to the collecting tubules* has first to pass through such units. The vascular arrangements are peculiar in that the tubules, *both cortical* and medullary, are supplied exclusively with blood which has first passed through glomeruli (Huber[16]) and given up more or less filtrate. The capillary network around the tubules is abundant and anastomoses freely, so that there can be no question of the efferent arteriole from one tuft supplying only its own tubule.

According to the modern theory the whole of the process *of extrusion* of excretory products from the blood occurs by *filtration* of protein-free plasma under pressure from the tufts and this is concentrated *in the* tubules by reabsorption of almost all the water along with threshold bodies while only purely excretory products and useless excess of threshold materials remain in the formed urine. The amount of urine may represent only about a hundredth part of the original filtrate, ninety-nine parts having been taken back, so that the large variations of urinary output which can occur under natural conditions would obviously be most easily accounted for by slight alterations in the proportion reabsorbed. A 100 per cent. rise in daily output of urine from a normal 1·5 litres to a polyuria of 3 litres would result from a drop in reabsorption from 99 to 98 per cent., *a difference of only 1 per cent.* Similarly a fall in urinary output to one-half the normal would entail *only a 0·5 per cent. increase in the amount of filtrate* reabsorbed. Such variations in urinary output would not at the same time involve *alterations in* the time/amounts of excretory substances eliminated so long as their titre in the plasma and the *rate of* original filtration did not vary.

In the large exchanges of fluid which are involved by this hypothesis certain factors can be recognised which must tend to influence the amount of reabsorption in an upward or downward direction.

Firstly, the blood supplying the tubules, having been concentrated by loss of the filtrate, has acquired a raised colloid osmotic pressure: when the hydrostatic pressure is lowered in passage to the wide capillary network of the labyrinth this raised oncotic pressure provides energy which is expended in again taking up fluid. The force thus supplied at any time is no doubt of a low potential but it is constantly maintained so long as blood flow and glomerular filtration continue; when *multiplied by a* factor representing the large volume of renal blood flow *of 2 to 3 c.cm. per gramme per minute, it must* amount to a considerable total in the course of a day, during which period only a relatively small volume of fluid is elaborated as urine. Since this is work which is done by the circulation it is so much which is not done by any special vital activity of the renal cells. It may be remarked that in respect of outward passage of fluid from capillaries where the blood pressure is higher and the recall of it by the osmotic pressure of the plasma colloids where the hydrostatic pressure is lower, the above scheme is *identical* with that which was formulated by Starling[18] to account for nutritional irrigation of tissues from the capillaries and for lymph formation. From a consideration of the phylogeny of nephridia there is nothing very fanciful in the conception of renal excretion as a specialised modification of the formation of lymph: it is a conception which would exercise the same mechanism in the regulation of blood volume, as in what has been called by F. C. McLean [19] the regulation of body volume, so far as this is carried out by the kidney.

A second factor that can be recognised, this time working in the opposite direction, is the amount of urea and other excretory crystalloids in the lumina of the tubules. It is readily apparent that, while all other tissues in the body are freely permeable to urea, the cells of the renal tubules, and for that matter the epithelium of the whole urinary tract, are when normal relatively impermeable to it in a direction from lumen to blood stream. On no other consideration would it be possible to obtain the high concentrations of urea that may be found in normal urine. As has been shown (Dunn, Haworth, and Jones,[20] Dunn and Jones [21]), when the first convoluted renal tubules are injured by soluble oxalates while the circulation remains intact, the concentrating power of the kidney fails, and urea is retained in the blood. Later experiments, unpublished, have revealed the same effect in nephritis produced by uranium, cantharidin, and mercuric chloride, where also the first convoluted tubules are selectively damaged: the phenomenon occurs even with slight degrees of epithelial injury, and not only, as Gray [22] has assumed, when they are completely necrosed; if the damage is severe anuria results, presumably because the necrosed tubules have lost all capacity to regulate the passage of fluid and the latter finds its only escape from the kidney via the blood stream. In uric acid nephritis also (Dunn and Polson [23]), where the first convoluted tubules escape injury but the ascending limbs of Henle's loops and the second convoluted tubules are affected, exactly the same retention of urea with temporary oliguria or anuria is observed: the intactness of these lower segments is obviously as essential to a maintained concentration of urea as is a healthy state of the upper, apparently more highly specialised ones.

Since then urea is normally held in the lumina of the tubules it cannot but exert its physical osmotic property by holding back water from reabsorption through the cells into the blood. It is essentially on the basis of this view that the diuretic effect of medicinal doses of urea is usually explained, and there is no reason to doubt that the lesser amounts present naturally in the filtrate act functionally in the same way. When we remember the great length of the tubules it seems not at all unlikely that but for this normal diuretic action of urea the whole of the filtrate would always be reabsorbed, leaving nothing for excretion.

The Balance of Nephron Activity

It is not suggested that these two antagonised factors are the only ones which bear on the normal regulation of urinary volume, but it appears probable that in any scheme involving much filtration and reabsorption they must from their constant activity play a very large part in this; accordingly a very exact correlation of their action must be necessary in order to ensure that neither too little nor too much reabsorption occurs to suit the needs of the organism for fluid balance—in other words, that the correct volume of urine is eliminated.

In attempting to visualise a process whereby the above correlation could be upset as a result of glomerular disease, so as to produce excessive reabsorption of water and salt, without at the same time having diminished glomerular filtration, and therefore retention of urea, it has occurred to me that an explanation might be found in a disturbance of the normal alternation of glomerular, and therefore of nephron activity.

The view that the glomeruli are not continuously in action, but that they open up and close down intermittently has been firmly established for the kidney of the frog by the remarkable pioneer work of Richards and Schmidt.[24] They observed under the microscope not only alternating action of capillaries in the same tuft, but also temporary cessation of blood flow in whole tufts for unequal periods. In mammals direct examination of the tufts in action has so far proved impossible, but the experimental results of Khanolkhar [25] and of Hayman and Starr [26] in rabbits using indirect methods of intra-vital injection give good grounds for the belief that this is a universal process in the kidneys of higher animals as well.

Seeing that such an alternating action of the glomerular capillaries would only bring them into line with what is known of these vessels in other tissues where they can be directly observed during life (Krogh [27]), I will assume it to be a fact and will consider the effect that it may have on the activities of the nephrons.

The rate and degree of intermittent action of the tufts in man cannot be projected, but if we assume for the sake of clearness the extreme condition of one glomerulus out of three being open at a time, then we may regard a group of three adjacent nephrons as representing fractionally the whole activity of the kidney. We will then recognise that during any period the filtrate from the glomerular blood is passing to only one tubule to be concentrated, and that the process of reabsorption is aided only by the blood in the capillaries around that tubule; acting in the opposite direction we have the osmotic power of all the urea in that amount of filtrate. If now we assume for contrast that all three glomeruli are open at once, but that the total renal blood flow is unaltered, we will then have each tuft working continuously, but each with only one-third of the blood which formerly passed through one, and we will have three tubules each receiving one-third of the filtrate and urea which formerly went to one. Thus the same total amount of filtrate will be subjected to reabsorption over an area three times as large as before, and with the aid of the same raised oncotic pressure of blood proteins as before, but greater in extent because the capillary area around three tubules is in action. Against these factors tending to increase reabsorption we will have in the same period only the same total amount of urea as before, divided to three tubules, tending to hold fluid in the lumina. There will thus in the latter case be a liability for less fluid to remain in the tubule for excretion—in other words an oliguria, but with normal elimination of urea. As has been stated, the case taken as normal is the extreme one of cessation of activity of two out of three nephrons at a time, but with a less strict degree of alternation the same principles would hold good.

Disturbance of Glomerular Function in Nephrosis

In the application of the theoretical considerations set out above to the interpretation of the phenomena of human disease, it has already been suggested[14] that in diffuse glomerulonephritis the changes in the glomerular capillaries, which are partly blocked by thickened endothelium, would account for interference with the intermittent action of the tufts and so bring about the disturbance of balance already outlined. In this disease there is frequently no doubt a considerable degree of obstruction to blood flow in all the tufts, and a rise of blood pressure commonly results; the view is hardly tenable, however, that oliguria is in this case due to diminished total blood flow and lessened glomerular filtration, for in many instances oliguria and œdema are present while elimination of urea is still only slightly, if at all, impaired. To explain this state of affairs, if renal blood flow were much diminished, it would be necessary to assume that the diseased kidney was able to separate urea from the blood at a better rate than the normal one.

The condition of the glomeruli in nephrosis has always appeared to negative any possibility of an explanation of oliguria based on a change in the capillary vessels. Fahr's [11] account of them mentions slight general hyalinisation or thickening of capillary basement membranes but with maintenance of the lumina, wide and often empty of blood. Slight increase of endothelium may occur, and some cells may show fatty degeneration, but stigmata that might be of inflammatory origin are very slight, and there is often no histological grounds for assuming any obstruction to blood flow. In agreement with this, as is well known, the blood pressure in such cases is normal and hypertrophy of the heart does not occur. The continuance of a normal blood flow is also indicated by the absence of rise of blood-urea over long periods while oliguria and œdema continue.

The further suggestion to be made as to the significance of the glomerular changes here is based on the results of staining the capillary basement membranes by Mallory's connective tissue method.

This reveals the fact, not apparent by ordinary staining, that in addition to the slight diffuse thickening of basement membrane, there is a fixed patency of the capillary lumina in all the tufts, whether empty or blood-filled, in contrast with the conditions in normal kidneys where these exhibit all varying degrees of collapse or distension and a distended state is usually accounted for by the presence of red blood corpuscles. The ends of the arterioles in the tufts are also usually more widely patent than normally. The state of fixed patency of the capillary lumina is similar in general aspect to what has been described and figured by Baird and Shaw Dunn [28] in the nephritis of pregnancy and eclampsia, which is classified by some as a nephrosis.

The interpretation which it is proposed to place on this appearance is that from its constancy and diffuseness it is a significant change, and that it is an indication of abolition of the normal rhythmical contractility of the capillaries, whether that property belongs to their whole length or only to their arterial ends. In some instances the flaw has probably resulted from mild antecedent glomerulitis, seeing that minute adhesions occur as well on many of the tufts; in other cases definite signs of old glomerulitis are lacking, but it is not meantime considered that an inflammatory origin is ruled out. So far as function is concerned, the condition appears to provide a basis for unbalanced over-reabsorption of glomerular filtrate on the lines already indicated, with resulting oliguria. As the blood pressure in these cases has been normal, there is no reason to suppose that the arterial distribution to the kidneys as a whole has been different from normal, so that the permanent patency of the glomeruli would not mean an increased perfusion of the kidneys but only a permanently uniform distribution of the available blood.

ALBUMINURIA

The heavy and continuous escape of protein in the urine in nephrosis has often been considered almost as difficult to account for as the oliguria, by reference to the renal lesion. The view that this protein is eliminated because it is abnormal and not because of disease in the kidney (Epstein,[29] Thomas, Schlegel, and Andrews [30]) has not found confirmation, and with the support of Hewitt's [31] polarimetric analyses the majority of workers seem to regard it simply as serum protein, accounting thus for the low level of the plasma colloids. It is also generally believed to come direct from the glomeruli rather than the tubules, and the greatness of the loss is supposed to depend upon an abnormal permeability of the capillary walls (Fahr,[11] Gray [13]), though this is not easy to account for. It is, in fact, difficult to suggest any analogy in disease elsewhere in the body for an escape of a high concentration of protein from the capillaries which lasts so long and which is associated with such slight alterations in these vessels as we find in the glomeruli of nephrosis. The implications of the modern theory of excretion are again of particular importance in this connexion.

If we accept that urine is concentrated by reabsorption of, say, 99 per cent. of the glomerular filtrate we must recognise that a high albuminuria, say 2·5 per cent., can only result from the escape of a quite low titre, 0·025 per cent. of protein from the tufts, unless there is very active reabsorption of protein by the tubules. That the percentage of protein in the original glomerular filtrate must be low is also indicated by the great volume of the renal blood flow; at a moderate estimate this will normally amount in the human subject to between 800 and 900 litres per day, and as has been pointed out, in nephrosis with normal elimination of urea it is probably little if at all reduced. At this rate of flow an albuminuria of 20 g. per day would be accounted for by a loss of not more than 0·025 g. of protein from every litre of blood passing through the kidneys. Even with the plasma proteins reduced to one-half of their normal concentration this represents a very slow rate of leakage of protein from the capillaries; in the large volume of filtrate demanded by the modern theory the original percentage of protein may indeed be no greater than that which is found in the œdema fluids of this disease. Histological examination also, so far as it goes, would support the view that the protein content of glomerular filtrate is low and that concentration occurs in the tubules; albuminous deposit is rarely abundant in the capsular spaces while on the other hand solid casts are commonly seen in the lower tubule segments.

To account for this continuous slight loss of protein from the glomerular capillaries reference is made again to the interpretation of their functional condition which has been outlined above. The suggestion has been made that in all the tufts these vessels are permanently open, and that each tuft is being continuously perfused, but at a much less rate than is normal for an active tuft. This amounts to a permanent state of stasis with slight dilatation, a condition which, according to Krogh,[27] invariably results in the escape of more or less plasma protein from capillaries whose walls are otherwise normal. This explanation of the albuminuria of nephrosis has already been put forward by Govaertz and Cordier [32] as an alternative to a continuous action of some toxic agent, and it seems to fit the known facts much better than the latter hypothesis. The high level of the albuminuria at first sight, no doubt, seems to imply a severe damage of the vessels, but if such were present could the condition be expected to persist unchanged for so long as it does? The albuminuria of nephrosis may endure for many months, and at the end the glomerular changes are often only of the mild character already described. The suggestion given here attributes the high *percentage* of the albumin in the urine to the process of concentration by reabsorption of fluid in the tubules; its large daily *amount* is explained by a slight but constant deduction from the large volume of blood which passes through the kidneys in the day, and it refers the *escape of protein* from the glomerular capillaries to a more or less mechanical occurrence, the validity of which in other situations has not been doubted. It also makes no further assumptions regarding the structural and functional changes in the tufts than those which have already been made to account for the oliguria.

TUBULAR CHANGES

In this attempt to explain these cardinal phenomena of nephrosis, oliguria, and albuminuria, on the basis of changes that can be seen in the tufts only, it may appear that the well-known tubular lesions have been forgotten. The appearances of fatty and lipoid deposit, of hyaline droplet change, and of foamy swelling, are certainly often prominent in old-standing cases, but as Mayrs [33] has pointed out there is no evidence that the presence of these abnormalities interferes at all with one of the highest known functions of the tubule cells, that of concentrating urea, so that these cannot be supposed to be seriously degenerated. As has already been suggested by Aschoff [34] and by Govaertz and Cordier,[32] the presence of these abnormal substances in the cells may well be due to their having been reabsorbed from the filtrate in the tubules; hyaline droplet change is probably a reabsorbed protein, while the lipoidæmia always present in these cases will account for the large lipoid deposits sometimes seen. The prominent tubular appearances of nephrosis would, therefore, be accounted for, like the oliguria and the albuminuria, by the essential and primary lesion in the glomeruli.

Application to Other Forms of Nephritis

The view which has been presented of the interrelationship of structural change with renal functional disturbance has here been propounded almost solely in its bearing on the phenomena of nephrosis, but it is considered that the same principles would apply to the elucidation of those signs and symptoms which are shared with nephrosis by other forms of Bright's disease. On this basis it would become possible to comprehend the great clinical similarity of pure "tubular" nephritis or nephrosis to glomerulonephritis of nephrotic type, at a time when the latter has not yet revealed its true nature by a rise of blood pressure or the development of urea retention. In nephritis of pregnancy, where oliguria, œdema, and albuminuria are often accompanied by good urea excretion, it is now known (Fahr,[35] Bell,[36] Baird and Shaw Dunn [28]) that a slight but diffuse glomerular lesion exists which sometimes resembles that of nephrosis and sometimes a mild intracapillary glomerulitis; tubular changes, if present, are qualitatively the same as in nephrosis.

Amyloid disease of the kidney is occasionally associated with a clinical picture indistinguishable from that of nephrosis (Volhard [37]), and here we have, no doubt, as the primary pathological development an alteration of the glomerular capillary walls which may well interfere with their functional activities, while the tubular changes are again the same as in nephrosis or subacute glomerulonephritis.

In the promulgation of a theory which would account for oliguria and albuminuria in all œdematous nephritis purely on the basis of renal morbid histology and physiology, it is obviously impossible at the present time to submit completely verified facts in support of every contention, and in what has been written above resort has frequently been made to what are regarded as theoretical probabilities. The main assumption that has been made, and by it the argument stands or falls, is the correctness of the filtration-reabsorption hypothesis of urine formation. Exactly how this theory stands nowadays it is difficult to assess; many physiologists appear to accept it wholly or in part, and while a complete scientific proof that it is the sole basis of urine formation in mammals is hard to secure, the work of A. N. Richards and his collaborators,[38 39] has gone far towards a direct demonstration of its truth in animals with accessible glomeruli. So far as the present communication is concerned, the matter may be viewed in another light. It is a reasonable presumption in pathology that in disease an organ performs its function in a manner as nearly normal as the interfering factors will allow, and does not proceed to act on some entirely different principle. A theory of normal functionation which cannot be fully established is thus submitted to test when it is applied to the elucidation of the abnormal physiology associated with disorder of structure. In this respect it does not appear too much to say that the secretory theory of renal activity, involving glomerular filtration of only the amount of fluid which appears as urine, has been tried and has failed to provide a common type of cause for oliguria which may be combined with good urea concentration. If the logical application of the modern theory will provide such a principle it will be so much in confirmation of the validity of that hypothesis.

ST. GEORGE'S HOSPITAL.—In 1933 in-patients totalled 5238, of whom 427 were children under 12. Their average stay was 20·26 days, and 20·74 per cent. of them were sent on discharge to Atkinson Morley's Convalescent Hospital. The weekly cost per patient was £4 10*s.* 4*d.*, an increase of 2*s.* 4*d.* There were 36,827 out-patients who cost a fraction over 7*s.* 6*d.* each. At £82,518 the ordinary expenditure showed a deficit of £84; the bank overdraft was £35,517.

SPINAL ANÆSTHESIA *

By H. K. Ashworth, M.B. Manch.

VISITING ANÆSTHETIST, MANCHESTER ROYAL INFIRMARY AND ANCOATS HOSPITAL

At the present time the majority of anæsthetists in England probably use one of the following drugs or preparations of drugs: Stovaine, Duracaine, Spinocain, Percaine, and Novocain crystals dissolved in cerebro-spinal fluid.

The ideal drug (as yet non-existent) for subarachnoid nerve-block:—

(1) Should be slightly lighter than the cerebro-spinal fluid, and this relationship should remain constant as long as the drug is active;

(2) Should have a high degree of local action on, and be rapidly "fixed," by, the nerve-roots;

(3) Should have a slow rate of blood absorption;

(4) Should be easily administered and easily controllable;

(5) Should maintain its anæsthetic effect for as long a time as is required.

None of the five preparations mentioned fulfil all of these criteria, and when such a drug is invented many of the existing difficulties of subarachnoid block will disappear.

Stovaine is the oldest of the preparations in common use, and for many cases is still pre-eminent. It has the advantage, first, that the manipulative technique required for a successful administration is small, since an adequate dose is contained in a small volume of solution and it requires little or no mixing with the cerebro-spinal fluid. Moreover, Barker's solution is considerably heavier than cerebro-spinal fluid and gravitational diffusion is all that is needed to obtain the required height of anæsthesia. Secondly, stovaine has the merit of being rapidly "fixed" by the nerve-roots, so that it is perfectly safe to place a patient in full Trendelenburg position 15 minutes after injection, without fear of any upward spread which might paralyse the anterior roots of the phrenic nerves. The one possible disadvantage of stovaine is that its action is transient, and anæsthesia in the upper abdomen rarely lasts for longer than 45 minutes.

Spinocain enjoyed a great vogue a few years ago but is now becoming increasingly discredited. It is an alcoholic preparation of novocain with a specific gravity slightly less than that of the cerebro-spinal fluid. Owing to the greater rapidity of absorption of its more volatile alcoholic constituents, the relation between its specific gravity and that of the cerebro-spinal fluid becomes a variable and unknown quantity after injection, with the result that neither accuracy of the anæsthetic level nor certainty of fixation can be obtained.

Duracaine is a somewhat similar solution but heavier than the cerebro-spinal fluid and without the strychnine present in spinocain. Novocain solutions are claimed by their users to be less toxic than stovaine or percaine. Doubtless this claim may be substantiated in the experimental laboratory, but it does not hold good in clinical practice. Novocain, because of its weaker anæsthetic properties, has less affinity for nerve-roots than its much stronger rivals and this lack of affinity is in itself a source of two possible dangers. First, it is difficult, if not impossible, accurately to gauge the time in which such solutions are fixed and the patient may safely be placed in the Trendelenburg position without fear of phrenic paralysis. Secondly, the novocain which is not taken up from the cerebro-spinal fluid by the nerve-roots passes into the blood stream, and as a large dose of this comparatively weak anæsthetic agent is commonly injected in the process of spinal anæsthesia, the amount absorbed from the blood is by no means negligible.

Percaine.—The nearest approach to the ideal drug for spinal anæsthesia at present known is probably the 1 in 1500 solution of percaine in 0·5 per cent. saline. Percaine is slightly lighter than the cerebro-spinal fluid and this relationship remains constant so long as the drug is active. The one disadvantage is that the large volume of the required injection increases the margin for manipulative errors during administration. Percaine has the great merit of permitting accurate dosage, using the method described by Howard Jones. With the patient in the lateral flexed posture, the spine is measured in inches from the vertebra prominens to the spot at which it is crossed by a line joining the highest point of the iliac crests. From this measurement a subtraction is made of 4 for a man, 6 for a woman, and 7 for a child of 8–10 years of age. The resulting number, expressed in c.cm. of percaine solution, represents the dosage which should be injected at the level of the second or third lumbar interspace in order to obtain anæsthesia extending as high as the fifth dorsal nerve-roots. This is the level required for full abdominal anæsthesia. The formula works in practice, and it is found that the height of anæsthesia always lies between the third and fifth dorsal nerve-roots. For subumbilical surgery there is no need to measure the patient, and 10–12 c.cm. will always suffice to provide anæsthesia for such operations as prostatectomy, hysterectomy, or herniotomy. Another advantage of percaine is that it is the only spinal anæsthetic which can safely be given and the patient then left upon a flat table or trolley, provided that the ventral decubitus is adopted; there is no fear of the anæsthetic spreading either too high or not high enough. Much time can often be saved by administering a spinal anæsthetic in the anæsthetic room instead of waiting until the operating-table has been vacated by the previous patient.

THE CHOICE OF DRUG

I should, however, like to suggest that every patient should receive the preparation most suitable for the condition and operative need of that particular case, and not simply a routine dose of the anæsthetist's pet preparation. This statement does not imply that an anæsthetist should use a different preparation for every subarachnoid block, and thus risk failing to obtain a thorough technical and physiological understanding of any drug. For example, Barker's stovaine Billon cannot, in safe dosage, be guaranteed to maintain upper abdominal anæsthesia for more than 45 minutes. It seems to me for this very reason to be the best existing drug to use for subarachnoid block in urgent abdominal surgery if a spinal anæsthetic is required. Most urgent abdominal operations should be, and usually are, performed within this space of time, and by using stovaine with its comparatively transient effect the patient is, from the anæsthetic standpoint, restored to physiological normality as soon as possible after the operation is completed. Among examples of the benefits often conferred by this procedure may be mentioned:—

1. There is less risk of respiratory complications, since the lower intercostal muscles are paralysed by the anæsthetic for a minimum period of time.
2. The patient may be nursed immediately in the most favourable surgical position indicated, without reference to the anæsthetic.
3. He may immediately, if surgically indicated, take fluids by the mouth. Or again, Barker's solution, with its

---

* Read before the Liverpool Society of Anæsthetists.

specific gravity of 1025, drops immediately into the sacral recess if injected into the subarachnoid space with the patient sitting upright, thus providing an excellent, localised, and adequately long "saddle area" anæsthesia, ideal for such operations as hæmorrhoidectomy or cure of fistula-in-ano.

Conversely, percaine solutions, which will maintain abdominal anæsthesia for two hours, are obviously more suitable than stovaine for an operation such as resection of the colon but as obviously unsuited for the performance of hæmorrhoidectomy. My own practice is to use either percaine or stovaine, according to the needs of the case, basing my choice on the lines indicated above, and I do feel that, when a spinal anæsthetic is decided upon, the anæsthetist should think a step further than a mere routine dose of any single drug.

CONTRA-INDICATIONS

There are five absolute contra-indications to subarachnoid nerve block. They are: (1) organic disease of the nervous system, e.g., disseminated sclerosis, meningitis; (2) recognised mental abnormality; (3) pyæmia; (4) septic disease in the route of injection, e.g., cellulitis of the back; and (5) operation above the diaphragm. Relative contra-indications are :—

1. Deformity of the spine in which intrathecal puncture is difficult or impossible.
2. Low pre-operative blood pressure. This often provides one of the most difficult problems which are presented to an anæsthetist. It is impossible to fix an arbitrary low-level limit, and every case must be judged individually.
3. Very young or highly strung patients should not be subjected to spinal anæsthesia unless their consciousness can be both adequately and safely damped down by suitable pre-operative medication; in this connexion the words "adequately" and "safely" are, unfortunately, not often compatible.
4. The presence of any disease which is associated with a great depletion of the blood volume. Abdominal hæmorrhages and acute intestinal obstruction are in this category although, paradoxically, intestinal obstruction provides one of the greatest indications for spinal anæsthesia. The apparent paradox can be resolved by pointing out that, whereas in cases of acute intestinal obstruction the blood volume can be safely increased by the intravenous administration of at least 2 pints of normal saline solution before operation, the same procedure cannot be carried out safely in the presence of uncontrolled hæmorrhage.
5. The performance of any operation which involves violent or noisy procedures which are likely to be very disturbing to a conscious patient. Many orthopædic operations fall within this category.
6. Any operation in which a large degree of surgical shock is probable.
7. Operations on the kidney. The lateral kidney posture is an extremely unpleasant one for a conscious patient; any difficulty in delivery of the upper pole often causes pain owing to the involvement of the diaphragm, and the bridge hinders the circulation by preventing a free return of blood via the inferior vena cava and thus increases the risk of any fall in blood pressure.

INDICATIONS

The three absolute indications are: (1) The presence of serious disease of the respiratory system, e.g., phthisis or bronchitis. (2) Acute intestinal obstruction with distension. In these cases the operative facility provided by spinal anæsthesia outweighs the often grave risk of the slight additional fall of blood pressure in an already collapsed patient. (3) For lumbar sympathectomy. Besides providing the perfect muscular relaxation necessary for this operation, spinal anæsthesia provides a valuable prognostic guide as to whether operation is likely to result in permanent improvement in the circulation in the legs.

The relative indications for spinal anæsthesia are probably the most controversial of any, and the following list represents purely personal opinions :—

1. Urgent abdominal surgery in adults, with the exception of that necessitated by hæmorrhage or associated with extremely low blood pressure. In addition to the benefit conferred on the surgeon by providing him with the greatest possible amount of muscular relaxation when most he needs it, the patient has finished receiving all harmful anæsthetic effects within a few minutes of the end of the operation, and has no extra strain to bear of the post-operative excretion and sequelæ associated with general anæsthesia.
2. Genito-urinary surgery, and particularly prostatectomy, but excluding, as a rule, operation on the kidneys unless renal function is so poor that excretion of a general anæsthetic might be a dangerous post-operative strain.
3. The presence of metabolic diseases, e.g., diabetes mellitus, or damage to excretory organs, e.g., cirrhosis of the liver, Bright's disease.
4. The presence of cardiac disease, with the exception of aortic incompetence.
5. The rare patient who dreads unconsciousness during operation more than consciousness.
6. Long operations in which muscular relaxation is essential and in which, therefore, the patient would otherwise need a lot of ether, thus adding to the harmful stimuli received. As examples of this class of case may be mentioned gastrectomy, resection of the colon, and abdomino-perineal resection of the rectum.
7. The type of patient who would be difficult to control or adequately to relax under a general anæsthetic, i.e., cases in which the amount of general anæsthetic required would be disproportionately great in comparison to the operation to be performed. The commonest examples are the professional footballer with an internal derangement of the knee-joint, the policeman with hæmorrhoids, or the publican with a fractured patella. In such cases spinal anæsthesia relieves the anæsthetist from what often used to be a very damaging and exhausting struggle during induction.
8. Amputation of the leg, provided that due precautions are taken to prevent the patient from being aware of the sawing of bone.
9. Herniotomy. In addition to providing an easy and safe anæsthetic for the radical cure of hernia, spinal anæsthesia diminishes the risk of the post-operative cough which is particularly undesirable in such cases.

PREMEDICATION AND "COMBINED" ANÆSTHESIA

Consciousness is undoubtedly the greatest disadvantage of spinal anæsthesia. Many attempts have been made to overcome this by varieties of premedication. A small dose of a basal narcotic combined with spinal anæsthesia promised to be an ideal combination from the point of view of both patient and surgeon.

It has been found, however, that such a combination is too dangerous to be used in other than very exceptional cases. All preliminary narcotic drugs (except in very small doses) enhance the danger of central respiratory failure or fall in blood pressure under spinal anæsthesia. My own procedure is to limit preliminary narcotics to the administration of morphia gr. $\frac{1}{6}$ forty minutes before operation. This is accompanied by ephedrine grs. 1½, and I would stress the importance of administering ephedrine not less than twenty minutes before the time for the spinal injection. The object of this injection is to combat the fall in blood pressure caused by spinal anæsthesia. The technique commonly used is to administer a subcutaneous injection of ephedrine in novocain solution at the site and time of the lumbar puncture. This procedure is useless, as the subsequent subarachnoid injection paralyses the vasoconstrictors long before the ephedrine has had any chance to be absorbed from the subcutaneous tissue and exert its specific effects.

For "combined" anæsthesia gas-and-oxygen is certainly the best, but very light chloroform anæsthesia is preferable to ether, as the "midwifery" type of anæsthesia will suffice. True combined anæsthesia means that in which the inhalation anæsthesia is given purely to abolish consciousness, and not the disaster which sometimes occurs in everyone's practice of a "failed" spinal anæsthetic. Unfortunately, and for some entirely inexplicable reason, a patient with a "failed spinal" always requires far more general anæsthetic to become adequately relaxed than if no previous attempt had been made at subarachnoid block.

PRACTICAL POINTS

The first important point is to ascertain that the spinal anæsthetic is working satisfactorily.

No attempt should be made to test the efficiency of the anæsthetic upon any site which is not expected to be fully anæsthetised, or before sufficient time has elapsed after injection for anæsthesia to have developed. If a patient is once hurt the confidence of that patient is destroyed and is seldom completely regained. When testing anæsthesia, a sharp-pointed towel clip is the most satisfactory instrument to use. The patient should never be asked if he can feel anything or be allowed to see any test being performed, but the anæsthetist must watch carefully the patient's face. Imperfect anæsthesia will be shown immediately by a contraction of the orbicularis palpebrarum and, if very imperfect, the patient will screw up his entire face when stimulated. Anæsthesia does not develop at the same rate in every patient, and impatient surgeons must be firmly persuaded to give it a fair chance to develop. I have seen anæsthesia develop as long as 12 minutes after the injection of stovaine instead of the more usual 3–5 minutes.

The eyes of the patient should be kept covered during the operation, and with modern theatre lighting the screen alone is often insufficient to prevent the patient from developing a visual interest in the proceedings. Care must be taken to ensure that the eye-covering leaves the nose and mouth quite free.

As soon as the anæsthetic solution is considered to be "fixed," some degree of Trendelenburg position should be adopted in order to combat any tendency to cerebral anæmia resulting from fall in blood pressure. A small point is that if the operation necessitates a steep degree of Trendelenburg position, the wrists should be slung before the operation begins, as patients always complain that their arms are very uncomfortable when unsupported. Nausea or vomiting is best combated by the application of cold water to the forehead, and by instructing the patient to breathe deeply with the mouth wide open.

It should not be necessary to remind surgeons that the unanæsthetised chest of a conscious patient is not an ideal receptacle for heavy instruments, or that a patient should not be treated to a discourse on the state of his abdominal contents during their actual evisceration; but it is surprising how often these small points are neglected, although attention to them ensures that the operation is carried out with the minimum of discomfort to the patient.

CALCIFICATION AND OSSIFICATION IN THE SEMILUNAR CARTILAGES

By H. A. Harris, D.Sc., M.D., M.R.C.P. Lond.
PROFESSOR OF CLINICAL ANATOMY IN THE UNIVERSITY OF LONDON, AT UNIVERSITY COLLEGE AND UNIVERSITY COLLEGE HOSPITAL

In a recent number of the *British Journal of Surgery* two contributors have drawn attention to cases of ossification in the semilunar cartilage of the knee-joint. Two cases of ossification in the *internal* semilunar cartilage are described by H. J. Burrows,[1] and the condition is described as "a rarity bearing on the metaplastic formation of bone." Watson Jones and R. E. Roberts,[2] describing two cases of ossification in the *external* semilunar cartilage, state that this condition of ossification has not been hitherto described as distinct from the calcification described by Mandl and other observers.

In such clinical cases it is advisable to search to what extent, if any, normal anatomical parallels can be found in the domestic animals for conditions which are regarded as pathological in man. All animals which have a poor degree of conformity between the articulating surfaces of the tibia and femur have semilunar cartilages. They reach their highest development in man, the primates, and standing birds, such as the crane or stork. They are partly or totally suppressed in such forms as the bats which hang by their thumbs instead of perching or standing on their legs. The discs are developed in proportion as the knee-joint exhibits rotatory and sliding movements as distinct from mere flexion and extension. Whereas the internal disc is usually C-shaped, the external disc may vary from an incomplete annulus as in man to an almost complete disc as in the baboon, chimpanzee, and gorilla. An external cartilage in the form of a complete disc has been described in man by Duncan[3] and others.

As regards the function of the discs MacConaill[4] has pointed out how, with poor approximation of articulating surfaces, the disc, by its wedge-like cross-section, facilitates the early stages of movement. MacConaill has rightly associated this with the condition described by engineers in relation to lubrication. During the first phases of movement at any bearing surfaces a wedge-like film of oil of uneven thickness is more desirable between bearings than a film of equal thickness.

If the mode of formation of interarticular cartilages in the embryo be considered, a complete view is obtained of the structural changes which such discs may undergo. All interarticular discs are persistent portions of the original mesenchyme of the skeleton of the limb. There is no evidence for the view put forward by Bland-Sutton[5] that any extra-articular structure, such as tendon, ever contributes to the interarticular disc. A diarthrodial joint, such as an interphalangeal joint, is formed by localised absorption of the core of embryonic mesenchyme so as to demarcate the articular ends of the bone. In any diarthrodial joint with a disc two areas of absorption occur in close proximity, the intervening mass constituting the disc. The degree of absorption determines whether the disc shall be complete, as in the jaw, wrist, and sternoclavicular joints, or incomplete, as in the knee and acromioclavicular joint. Early stages of the demarcation of joints, with and without discs, are illustrated in “ Bone Growth in Health and Disease[6] (figs. 51-54). A later stage, at the knee-joint of the new-born rat, is shown (Fig. 1) to illustrate the histological identity of the two menisci with the cartilaginous ends of the bones. Afterwards, in the rat of about six weeks, the meniscus (Fig. 2) displays characteristic age changes in the cartilage. Near the joint capsule the tissue is essentially fibrous; near the periphery of the joint surfaces of the disc the tissue becomes more fibrocartilaginous both in terms of cells and fibres. At the centre of the disc the cartilage cells hypertrophy and become senescent. The matrix begins to calcify.

Some time later (Fig. 3) the mass of cartilage in the disc has reached such dimensions that it can no longer continue to live as cartilage proper. The problem of nutrition at the centre has become acute. The cartilage cells die, the matrix calcifies, and vessels from the capsule invade the zone. By a process which has much in common with aseptic inflammation, virtually dead calcified avascular senescent cartilage is replaced by vascular bone. At the periphery of the disc a narrow rim of cartilage persists which resembles in structure the hyaline cartilage near the articulating surfaces of the femur and tibia. This section (Fig. 3) shows very clearly a *fringe of synovial membrane* between the femur and tibia—a process of the ligamentum mucosum running from the infrapatellar pad of fat to the intercondyloid notch.

The relatively stable condition of the meniscus in the adult rat (Fig. 4) presents a disc in which a core of bone and marrow is surrounded by a narrow rim of calcified cartilage and a wider rim of cartilage which becomes more fibrous towards the free surface.

These progressive changes from undifferentiated mesenchyme to cartilage, fibrocartilage, calcified cartilage, and bone on the one hand, as in the rat and guinea-pig, or the change from cartilage to persisting fibrocartilage as in man, focus attention on the mode of nutrition of cartilage. Cartilage is essentially an avascular tissue in which the nutrition is carried on by imbibition of tissue juice. As in the case of a gumma or tubercle there is a limit to the size of such an avascular mass. Once this size is surpassed, the

FIG. 1

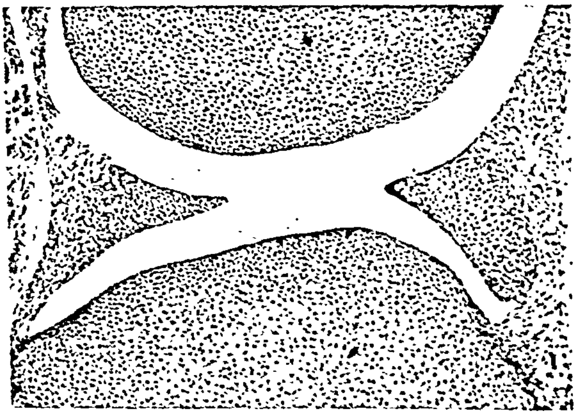

FIG. 3

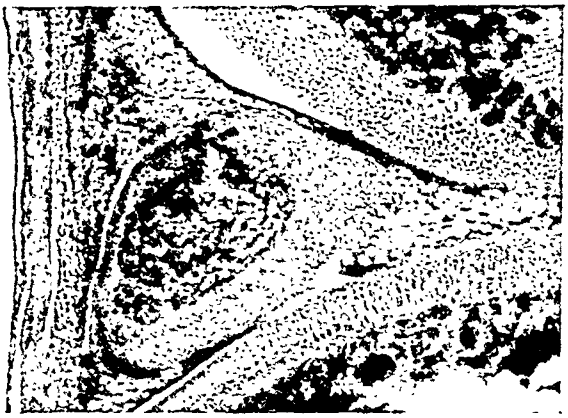

FIG. 2

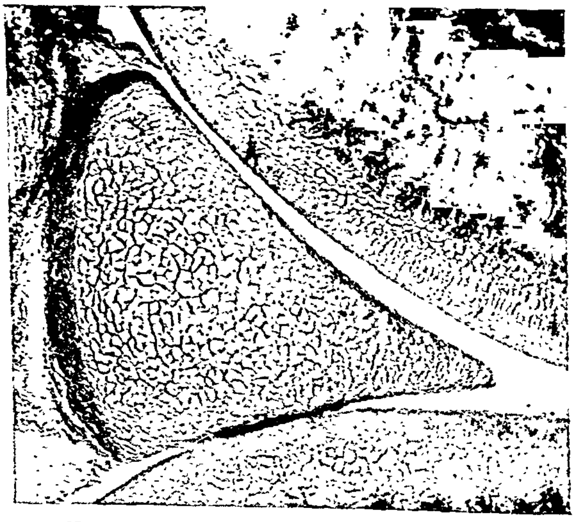

FIG. 4

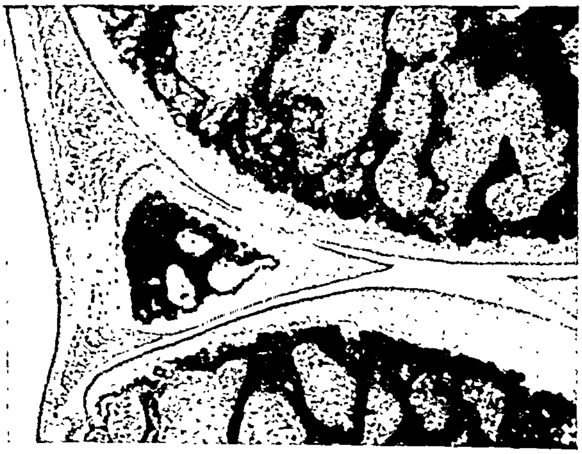

FIGS. 1–4.—Longitudinal sections of the knee-joint of the rat: (1) at birth (× 300); (2) at 6 weeks (× 130); (3) at 10 weeks (puberty) (× 155); (4) at 16 weeks (adult) (× 100).

cells at the centre undergo death with degeneration of the matrix, which may be either mucoid, fatty, or hyaline, and may be accompanied by calcification. Such calcified tissue may be replaced by bone. The intervertebral fibrocartilaginous discs of adult man, the mass of cartilage at the lower end of the femur in the new-born, the fibrocartilages of the ear and those of the larynx represent these limits of size. Whereas epiphysial cartilage, like diaphysial cartilage, undergoes calcification and ossification from within, fibrocartilages usually undergo calcification from without, on the free surfaces. This is shown by the laryngeal cartilages which in old age show small plaques of calcification on their surface, as is the case with the costochondral cartilages in old age or chronic respiratory disease.

The above facts should serve to distinguish between types of calcification and ossification in fibrocartilage. If the calcification and ossification is central in cartilage, it is usually part of the normal nutritional progression. If calcification occurs on the surface of a fibrocartilage it is essentially senile, allowing that such senility may be precocious as in the laryngeal and costal cartilages of patients with chronic bronchitis and emphysema.

If calcification and ossification occur in the centre of a mass of fibrocartilage it is usually consequent upon a localised zone of mucoid degeneration. Mucoid cysts of the semilunar cartilage, particularly of the external weight-transmitting disc, are not infrequent. Such areas of mucoid degeneration may undergo calcification and ossification as I have described[6] in conditions ranging from achondroplasia to stippled epiphyses.

This brief note has been written in order to warn the clinician and radiologist that calcification, or ossification, in the semilunar cartilages is not necessarily the cause of the derangement of the joint for which the patient seeks advice. If the calcified or ossified mass reaches such a size as to interfere with the surface contour of the disc then presumably symptoms must arise.

When Karl Pearson[7] undertook his intensive studies on sesamoid bones in man, he not only described calcified or ossified areas in the "fabella" of the external head of the gastrocnemius, but also in the tendon of the popliteus, and in the semilunar cartilages. He invented the term "lunules" to describe these small masses of calcified or ossified tissue in the semilunar cartilages, and it is suggested that the term, in view of the comparative anatomical significance, should be maintained, together with his designation of the sesamoid in the popliteus tendon as "cyamella."

CLINICAL AND LABORATORY NOTES

THE EFFECTS OF COMMON SALT IN ADDISON'S DISEASE

RECORD OF A CASE

By C. M. Hinds Howell, D.M. Oxon., F.R.C.P. Lond.

PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL AND THE NATIONAL HOSPITAL, QUEEN-SQUARE

The work done in recent years on the inorganic bases of the blood-serum in adrenalectomised animals was the subject of editorial comment in The Lancet (Jan. 20th, 1934, p. 137). In this connexion Loeb, among others, has shown a constant fall in the sodium content of the blood-serum in such animals. Further, he has found it possible not only to keep adrenalectomised animals alive by administering sodium chloride, but has also applied this treatment to patients suffering from Addison's disease with encouraging results. This is a matter of the greatest importance, since the present cost of potent cortical adrenal extract makes its general use impossible, and no other treatment has hitherto been found to give any relief in these distressing cases.

It seems desirable at this stage to record the result of treatment with sodium chloride even of isolated cases of Addison's disease. The following is a brief record of a case recently under my care in St. Bartholomew's Hospital, in which the findings differed strikingly from those reported in The Lancet of May 5th (p. 950) by Dr. W. Gordon Sears:—

A. B., a man aged 40, was admitted on Feb. 14th last, complaining of extreme exhaustion, nausea, and vomiting. He had noticed a peculiar pigmentation of his skin since August, 1933. Further symptoms began in November, 1933, characterised by weakness and lassitude, anorexia, dyspnœa on slight exertion, and œdema of the ankles, which he noticed at the end of the day. The symptoms had been steadily progressive. He had lost about 4 st. in weight.

His past history was unimportant and there was no history of tuberculosis in the family.

His pigmentation had the characteristic distribution and was well marked on the buccal mucous membrane. The area of cardiac dullness was much reduced and X ray examination of the chest showed the heart to be unusually small. The exact measurements were not ascertained by the orthodiagraphic method. The sounds were very faint, but otherwise normal. His pulse was regular, of small volume, and obviously of poor tension; rate 110 per minute. The blood pressure varied between a minimum of 60/40 mm. Hg and a maximum of 78/48 mm. Hg whilst he was under observation. There was no tenderness in either loin and no enlargement of the liver or spleen. The urine was acid; the specific gravity was 1012; it contained a trace of albumin. There were no other abnormal constituents. The Wassermann reaction was negative in the blood. His blood count on admission was: R.B.C., 4,700,000; W.B.C., 11,600; Hb., 81 per cent.; C.I., 0·86. There was a lymphocytosis present, with a polymorphonuclear leucopenia, the differential count showing polymorphs 3074, large lymphocytes 4698, small lymphocytes 2900 (total lymphocytes 7598). No abnormal cells were present in the blood film. Fasting blood-sugar was 80 mg. per cent. The blood sodium, estimated by Dr. G. A. Harrison, was 298 mg. per cent., which is the equivalent of 130 millemolecules. A control on healthy blood donors gave 324 mg. per cent. and 328 mg. per cent.; a patient with renal calculi gave 336 mg. per cent., and a man with ? sprue 346 mg. per cent.

The man's condition during his first week in hospital remained substantially unchanged. On Feb. 23rd, at the suggestion of Dr. George Graham, he was put on 10 g. of sodium chloride daily. This was given in 2 g. doses in milk. The patient experienced no difficulty in taking it. The effect of this treatment was most dramatic. After 24 hours the patient, instead of lying listless and apathetic as he had for the previous week, was sitting up looking at an illustrated paper. His nausea disappeared and his appetite improved at once. This improvement was maintained, and on March 7th the patient was allowed up. He stated that "he had not felt so well for months." The improvement was entirely subjective, as the blood pressure showed no rise, and the pigmentation remained entirely unaltered. On March 15th the daily dose of sodium chloride was reduced to 5 g. without the patient's knowledge. By March 26th he complained of feeling weak, lost his appetite, and vomited several times. The dose of sodium chloride was then doubled, again with an immediate improvement. The patient left hospital on April 5th. His blood pressure was unchanged, being 75/45 mm. Hg. His pulse-rate fell during his stay in hospital from 110 per minute on admission to 90 to 100 per minute when he was discharged.

Dr. Harrison estimated the blood sodium and found it to be 301 mg. per cent. on March 9th, when the man had been on sodium chloride 14 days. On March 19th, after four days of reduced sodium chloride (5 g.), the blood sodium was 315 mg. per cent. Unfortunately an estimation was not made of the blood sodium when the patient relapsed a few days later. It is remarkable that the blood sodium showed the highest reading when he was on half doses of sodium chloride.

During the period in which the patient was taking 10 g. of sodium chloride daily the hæmoglobin percentage in the blood fell steadily. It was 74 per cent. on Feb. 23rd, the day the treatment began, and had fallen to 65 per cent. by March 12th, although the patient was gaining strength and energy daily. During the period in which 5 g. only of sodium chloride were taken the hæmoglobin percentage rose again to 74 per cent. on March 20th and 84 per cent. on March 23rd. As was pointed out in the article in THE LANCET already referred to, it would appear that the adrenal controls the blood sodium, and that in Addison's disease there is a sodium leak from the body. Treatment with sodium chloride is obviously not in any way curative, but by supplying an excess, to some extent makes good the wastage.

The main differences between the case reported by Dr. Sears and my own are that in his case (1) the blood pressure was never really low and increased when a comparatively small amount (5 g.) of salt was being taken daily; and (2) the sodium in the blood-serum was very low (248 mg. per cent.) and rose with the small amount of salt to 452 mg. per cent.; whereas in my case the taking of sodium chloride caused only a very small rise in the serum sodium, although the man's symptoms improved enormously.

FRACTURE OF A SESAMOID BONE

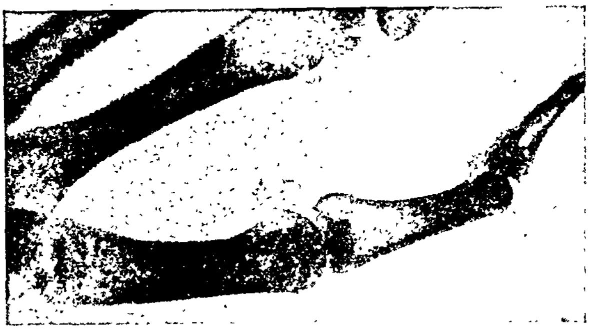
BY THOMAS STREATFEILD, M.D. Durh.

AND

H. F. GRIFFITHS, M.D. Camb.

IN view of the rarity of uncomplicated fracture of the sesamoid bones, the following case appears to be of interest.

The patient, a healthy schoolgirl aged 15, was seen by us together in June, 1933. She gave the history that whilst jumping a "horse" during gymnasium her right hand "got left behind," and she twisted her thumb. She was seen about one hour after this occurrence, when there was swelling and severe pain in the region of her metacarpo-phalangeal joint. A diagnosis of fracture of the metacarpal bone into the joint was made. Upon X ray examination it was found, however, that the sesamoid bone at the head of the metacarpal was fractured (see Figure). The left hand showed a normal sesamoid. The thumb was put up in full flexion and secured to the palm of the hand with strapping. It was kept in this position for five weeks, and a perfect functional result was obtained.



Fracture of sesamoid bone at metacarpo-phalangeal joint of thumb.

We are indebted to Dr. A. C. Rusack for his excellent radiograms.

Folkestone.

BILATERAL EMPYEMA

BY E. D'ARCY MCCREA, M.D., M.Ch. Dub.
F.R.C.S. Eng.

HON. ASSISTANT SURGEON TO THE SALFORD ROYAL HOSPITAL

BILATERAL empyema is an uncommon condition and a rarity in the adult. Keyes [1] defines it as a condition in which pus is found in both pleural cavities at or about the same time and points out that it is most frequently met with in association with broncho-pneumonia—for example, during the influenzal epidemics of 1917–19. The case records since 1910 number 69 (Steinke [2]), and three-quarters of the patients are less than 12 years old (Keyes). The example reported here possesses additional interest in that the fatal outcome may be attributed to a pneumococcal infection of the urinary tract.

The patient, a man 26 years of age, became suddenly ill on April 1st, complaining of a severe pain in the chest; compelled to return home from business he coughed up sputum tinged with bright red blood and the diagnosis made by his medical attendant was that of a left-sided pleuro-pneumonia. After a crisis the temperature became irregular and an extending dullness of the left side of the chest was found whilst on the right a well-marked area of paravertebral dullness appeared. He was admitted to hospital on April 16th, dyspnœic and with a very irritating cough; dullness on the left side reached the fifth rib in the midaxillary line. Sixteen ounces of thick greenish-yellow pus were aspirated and from this the pneumococcus type I. was isolated. The X ray findings appear in Fig. 1. Aspiration was performed again on April 19th, and 25 ounces of pus evacuated. On the 21st a rib was resected on the left side and closed drainage established which remained airtight for six to seven days. The dullness of the right side was, however, extending and on April 25th 15 ounces of pus similar to that found on the left side were aspirated; aspiration was again carried out on the 28th and on May 1st, and, respectively, 14 and 25 ounces evacuated. On May 2nd a self-retaining catheter was introduced into the right side through a trocar and cannula and continuous aspiration and irrigation as described by McEachern [3] commenced.

---

[1] Keyes, E. L.: Ann. of Surg., 1931, xciii., 1050.
[2] Steinke, C. F.: Jour. Thorac. Surg., 1933, ii., 287.
[3] McEachern, J. D: Brit. Jour. Surg., 1933, xx., 653

Progress was satisfactory until May 8th, by which time drainage from the right side had decreased from an original 40 ounces to 12 ounces per diem. However, on this date the temperature rose to 103·6° and the patient became very ill. The temperature fluctuated between 101° and 104° for seven days, after which death occurred. During this period no pocket of pus was found either by X rays (Fig. 2) or by the exploring needle which was used only on the left side as the right appeared clear on X ray examination. Post mortem a needle again failed to find pus in the thorax after careful search. Three days before death the urine was observed to be turbid and there was frequency of micturition; the day before death symptoms of cystitis were prominent, frequency of micturition was marked and associated with hypogastric and penile pain. The urine on microscopical examination contained numerous pus cells and on culture the pneumococcus type I. was identified.

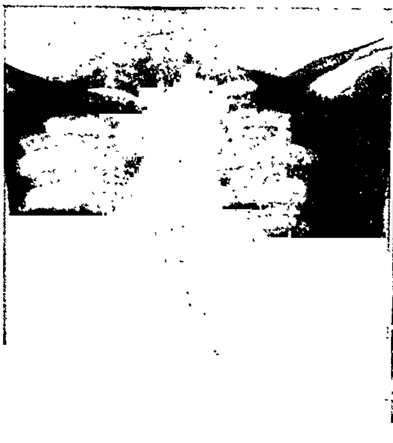


FIG. 1.—Before operation. Consolidation of both lower lobes and on the left side the shadow of a parietally situated empyema.

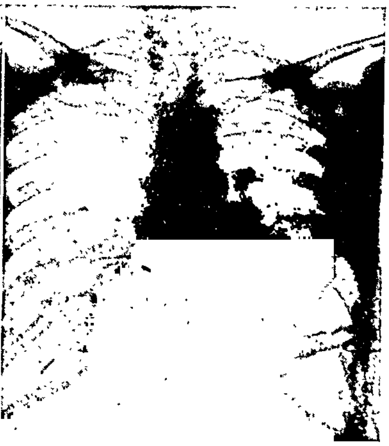

FIG. 2.—After operation. On the left side the drainage-tube is seen and on the right the catheter.

As regards the treatment of a bilateral empyema the first essential is the avoidance of a bilateral open pneumothorax during the early stages, and consequently open drainage is contra-indicated because further depletion of an already seriously diminished vital capacity in an exhausted patient is fatal. Therefore, guided by the condition of the individual patient, either aspiration alone of each side or closed drainage of one with aspiration of the other is the procedure of choice. Later in the disease when adhesions are firmly established bilateral drainage may be instituted; time should always be allowed for adhesions to become firm on the side first opened before operating on the second side.

In the patient recorded above McEachern's technique of continuous aspiration proved eminently satisfactory on the right side (Fig. 2), and I shall employ this method on both sides if another case presents itself.

At a meeting of this subsection held on May 16th, the chair was taken by Mr. W. E. Miles, the president, and a discussion on the

Treatment of Cancer of the Colon

was opened by Dr. F. W. Rankin (Kentucky). He based his surgical attack, he said, on physiological and embryological considerations, remembering that the colon was a dual organ. In most cases the problem offered by cancer was a chronic one which undermined vitality by a subintoxication. Measures therefore were preoperative, operative, and postoperative. The fundamental preoperative procedure was decompression, which might be accomplished in three to six days by surgical or by medical measures (saline irrigation and purging). Cæcostomy was the operation of choice, especially by Hendon's method. Rehabilitation was accomplished at the same time by giving a diet high in calorie value and low in residue (sugars and fruit juices), and by blood transfusions, which were very valuable. Transfusion should not depend on the existence of anæmia, but could well be used as a routine. He was doubtful of the value of routine vaccine; he had used streptococci and colon bacilli from fatal cases and thought it a useful step in rehabilitation and control of subsequent peritonitis, but it was not to be recommended as an alternative to other measures. Some old principles might well be re-emphasised: multiple-stage procedures; measures which did not call for primary sutures in the left colon; and aseptic end-to-side anastomosis, to by-pass the fæcal current, between the terminal ileum and the middle of the transverse colon, for right-sided growths. If a one-stage resection was decided on, it should be supplemented by an enterostomy proximal to the suture line. Obstruction might be due to œdema and infection, apart from any faulty technique, and might be fatal.

Dr. Rankin showed slides illustrating the technique he preferred for Mikulicz's operation, which he regarded as the third choice. The mortality had been much lower in his hands than any other left-sided procedure, but it must be preceded by adequate decompression. He also showed prognosis figures from a review of nearly 400 cases. They showed forcibly that Broders's index of malignancy was the most important yardstick for prognosis. Other factors influenced the result, but the grading was of primary significance. Glandular involvement followed the grade grouping. In his series glandular involvement was rather more frequent on the right side, but this side nevertheless showed a higher percentage of five-year cures than the left. Cancer of the rectum showed much more frequent metastasis. The five-year cure figures for the four groups were 63 per cent., 51 per cent., 31 per cent., and 24 per cent. respectively.

Dr. Rankin finally showed a cinematograph film of an end-to-side ileo-colostomy.

Sir Charles Gordon-Watson expressed agreement with Dr. Rankin's principles. In few surgical fields, he said, did judgment and experience play a larger part. In his experience many cases which at first sight seemed inoperable could be attacked after careful mobilisation. This variation made it difficult to assess statistics. Surgeons should aim at a high operability-rate, while trying to reduce the inevitably high mortality-rate that must accompany it. He showed figures from two series of cases. They showed the advantage of increased experience. In his later series the mortality for resections was 8 per cent., omitting one pulmonary embolism, and the operability-rate 63 per cent. The five-year survival-rate was, however, only 33 per cent. In the first series the operability-rate had been 57 per cent. and the mortality 20 per cent. Anæsthesia had been improved, and the enormous value of pre- and post-operative blood transfusion must be emphasised. "Drainage first" spelt safety first. A primary resection was, of course, never justifiable in the presence of obstruction, and every patient with a growth in the distal colon was potentially obstructed. A side-to-side anastomosis could seldom be done in the pelvic colon, but was usually possible in other parts and was much safer than end-to-end. There was less risk of gaseous distension and subsequent contraction.

Exteriorisation operations should be ascribed to Paul, of Liverpool, rather than to Mikulicz. Their advantages were inestimable. He was accustomed in cæcostomies to bring the tube through a portion of great omentum and then to fix to the abdominal wall. A safety-valve should always be used, to avert gas distension. Large hypertrophic growths often produced a lot of large glands, but the end-results were better than in the small scirrhous type as the glands were generally inflammatory and not malignant. Far less risk should be run in colloid cases, for few survived more than a few years, however good the surgery. He had tried in 1911 to immunise the peritoneum with vaccines, but had given it up, as he had found no marked benefit, and two successive vaccinated cases had died of streptococcal peritonitis. Animal experiments were needed on this subject. He was sure that better results could be obtained in the future, especially when more was known about the diathermy knife. There were possibilities in radium and X rays for advanced cases. With the million-volt X ray apparatus or the heavy bomb it would become possible to irradiate exposed growths. In ten years' time the mortality-rate would be down to about 5 per cent.

Mr. J. P. LOCKHART-MUMMERY also agreed with Dr. Rankin. One of the greatest points of all, he said, was preliminary decompression. Multiple-stage operations were of the greatest value. After colon anastomosis an elbow of small gut was apt to get caught up against the suture and acute obstruction resulted. He therefore stitched omentum or some other form of fat round the anastomosis. The most difficult cases were those of carcinoma in the lower end of the pelvic colon. The method he had suggested—a tubular resection—worked in some cases but was highly dangerous owing to the unsatisfactory blood supply to the part. It was important to stitch the arms of colon together carefully in Paul's operation so that no mesentery could get between the ends and so get caught in the clamp.

Mr. G. GORDON-TAYLOR said he was more inclined to perform Paul's operation than he had been five years ago. In fat patients suturing was difficult, and mobilisation carried with it no mortality: he had only lost one case. In easy cases end-to-end or lateral anastomosis was satisfactory, but always a cæcostomy was worth doing. In most cases there was no evidence of hepatic or peritoneal involvement; in this event it was worth while dealing radically. He had removed parts of the abdominal wall, stomach, and other viscera, and his temerity had been rewarded by long survival.

Mr. LAWRENCE ABEL thought that blood transfusion had lowered mortality, and recalled Mr. Wilfred Trotter's advice that when a growth was anastomosed it should be extra-peritonealised. He described his technique for effecting this, and expressed satisfaction with the Rankin clamp. Another way of preventing post-operative distention was to give continuous intravenous saline for two, three, or five days.

Mr. W. B. GABRIEL disagreed on the necessity for a cæcostomy; he thought that the old-fashioned Paul's operation could be done with perfect safety provided the proximal bowel was drained.

Dr. RANKIN briefly replied.

REVIEWS AND NOTICES OF BOOKS

The Queen Charlotte's Textbook of Obstetrics

Third edition. By ALECK W. BOURNE, TREVOR B. DAVIES, L. CARNAC RIVETT, L. G. PHILLIPS, C. S. LANE-ROBERTS, and LESLIE H. WILLIAMS. London: J. and A. Churchill. 1933. Pp. 679. 18s.

As a manual of practical obstetrics this book is admirable. The teaching is clear and dogmatic, and the division into short paragraphs with frequent headings makes it one of the most readable of text-books, and eminently suitable for the student. In physiology and pathology the information given on some subjects is rather meagre; for instance, very little is said about the physiology of the placenta, or the pathology of placental infarction.

The section on puerperal pyrexia and sepsis is especially good, embodying as it does the experience which the staff have gained at the new isolation block of the hospital. A chapter on the technique and results of vaccination is an unusual and very useful feature in an obstetric text-book. In the chapter on antenatal care stress is laid on the necessity for frequent urine examinations during pregnancy, but not on the greater importance of blood-pressure estimation, which is now recognised to be often an earlier sign of toxæmia. The section on cardiac disease is not so good as the purely obstetric parts, and would benefit from revision by a cardiologist. Obstetric operations are well described and illustrated, but the lower segment Cæsarean section, which is becoming increasingly important, requires detailed description.

The practitioner will find this book a full and reliable guide to obstetric treatment. Both student and practitioner will appreciate the sound advice offered on obstetrical diagnosis and treatment.

Eye, Ear, Nose, and Throat

By E. V. L. BROWN, M.D., Professor of Ophthalmology; LOUIS BOTHMAN, M.D., Associate Professor of Ophthalmology; GEORGE E. SHAMBAUGH, M.D., Professor of Otology; and ELMER W. HAGENS, M.D., Instructor in Otology. With the collaboration of GEORGE E. SHAMBAUGH, Jr., M.D., Clinical Assistant in Otolaryngology, University of Chicago. Chicago: The Year Book Publishers. 1933. Pp. 632. 11s. 6*d*.

As in previous years, this annual consists of abstracts from the current literature in these specialties of the previous 12 months; the papers abstracted have been selected with discretion from world-wide sources and have been skilfully summarised. In many cases editorial comments have been added which, though inclined to be dogmatic, are always shrewd and to the point. Of outstanding interest is the description by Dr. A. B. Duel of 12 cases of facial palsy operated on by the method developed by Sir Charles Ballance and himself; this consists in placing an autoplastic nerve-graft in the exposed Fallopian canal, and his description of the technique is so clear that it may be undertaken by any aural surgeon. He contends that the operation should be performed whenever facial palsy follows immediately the mastoid operation, and that a suitable graft introduced without delay gives assurance of a quick recovery. The abstracts cover a very large field, and this year's volume, like the former numbers, is a valuable work of reference. A good index of authors and of subjects is supplied.

Applied Pharmacology

Fifth edition. By A. J. CLARK, *M.C.*, M.D., F.R.C.P., F.R.S., Professor of Materia Medica and Pharmacology in the University of Edinburgh. London: J. and A. Churchill. 1933. Pp. 632. 18*s.*

EVEN in the short time—two years—since the last edition of this book appeared, the advance in pharmacological and therapeutic knowledge has made necessary the rewriting of some and the alteration of many of its chapters. The increasing employment of the barbiturates as basal anæsthetics; the introduction of new synthetic compounds, such as plasmoquine and atebrin in the treatment of malaria; the work on hæmatology, which has revolutionised the treatment of various forms of anæmia—are all dealt with fully from the theoretical and practical points of view; while an admirable summary of recent knowledge regarding the sex and other hormones is included. The chief characteristic of the book is the detailed description of the physiology of the various systems of the body, and the means whereby normal and altered function can be affected by drugs and other remedial agents such as sera and vaccines and radiations. The work thus meets in every way the needs of the senior medical student, and of the practitioner who may desire to refresh his knowledge of the scientific basis of his therapeutical methods.

L'artériectomie dans les artérites oblitérantes

By RENÉ LERICHE (Lyon) and PIERRE STRICKER (Strasbourg). Paris: Masson et Cie. 1933. Pp. 198. Fr.40.

THIS monograph emanates from workers who have already established their claim to write with authority on arterial disease. It is carefully and modestly compiled, and suggests that in arteriectomy the authors have given to surgery an operation of definite value in selected cases.

Attention is drawn to the fact that the degree of ischæmia following arterial obstruction varies with the manner in which the obstruction is produced. Plugging of the artery with an embolus produces a devastating gangrene; simple ligature produces a temporary ischæmia generally compensated for more or less completely by the collateral circulation; whereas excision of the segment of an artery causes practically no circulatory embarrassment, by reason of a phenomenal dilatation in the muscular and cutaneous vessels. This contention is supported by numerous experiments on dogs even to the extent of excision, in stages, of all the limb arteries, the aortic bifurcation and iliac arteries, leaving an artery-less dog, able to run as far and as well as any other dog. The authors ascribe the benefit of arteriectomy to the removal of the sympathetic nerves in the adventitia, and they regard the totally obliterated artery as a sympathetic nerve transmitting no blood but only harmful impulses and therefore to be put out of action by excision of a generous segment. Numerous indications for the operation are given, including causalgia, traumatic rupture and thrombosis of arteries, Volkmann's paralysis, arterial embolism of too long duration for embolectomy or after failure of embolectomy. Unfortunately little hope is offered even by enthusiasts for this operation in the treatment in Buerger's disease, since it is said to be only rarely indicated in localised "mono-arterites" definitely located by arteriography.

The book makes fascinating reading, being full of ingenious theories and suggestions for methods of dealing with cases which are usually condemned as incurable.

A Short History of the Epidemic Infectious Diseases

By E. W. GOODALL, O.B.E., M.D., Author of a Text Book of Infectious Diseases. London: John Bale, Sons and Danielsson, Ltd. 1934. Pp. 113. 3*s.* 6*d.*

ALTHOUGH, as Dr. Goodall points out, epidemic infectious diseases play an important part in medical practice, their histories have not hitherto been presented together in a single volume. He is well equipped to repair the omission, and within the space of some hundred small pages he has contrived to present the essential history of 17 epidemic diseases. Unlike many epitomes this is no colourless presentation of facts, but an extraordinarily interesting book rich in literary and historical allusion. Dr. Goodall finds space too for brief statements of his own considered views upon such debatable conditions as the Athenian "plague" described by Thucydides and the English "sweating sickness." He rather inclines to the opinion that the former may have been typhus; the latter he believes, with Hamer, to have been influenza. It is to be hoped that this epitome will be so successful as to encourage Dr. Goodall to write at greater length upon historical epidemiology, on which he is one of the few authorities.

Alcohol: its Effect on Man

By HAVEN EMERSON, M.D., Professor of Public Health Practice, Columbia University. London: D. Appleton-Century Co. 1934. Pp. 114. 3*s.* 6*d.*

Dr. Emerson has set out to write a small text-book for teachers and students explaining shortly the action and effect of alcohol on man, as far as they have been ascertained. On the whole his book is impartial and accurate. Although the author opposes the use of alcohol and regards it as deleterious to civilised peoples, he appears to have formed his opinion on reasonable grounds and to have produced ample evidence to justify it. He gives alcohol credit for most, if not all, of the virtues that can reasonably be claimed for it, such as its uses as a medicine and for the aged. He reprints from an earlier book an interesting and helpful scale of toxic symptoms associated with varying amounts of alcohol in the blood; 0·3 mg. per c.cm., for instance, produces mild euphoria—"Everything is all right"; "Sure I'll loan you some money." With 0·5 mg. the drinker "can lick anybody in the country," but has observable difficulty in lighting a match. With 1 mg.

he staggers perceptibly and sings loudly; with 3 mg. he sleeps and vomits by turns, and with 4 mg. he is in deep anæsthesia. Mr. Emerson's conditions for the permissible use of alcoholic beverages are as follows: he recommends everybody responsible for the safety or lives of others to avoid it altogether and advises healthy adults of sound nervous system to limit themselves to beverages with a content of less than 10 per cent., taken slowly, at or after meals. The book can be recommended as a skilful compilation of facts concerning alcohol in small compass, couched in language which is perhaps rather too technical for the audience he addresses.

The Toxicology of Plants in South Africa

Together with a consideration of Poisonous Foodstuffs and Fungi. By DOUW G. STEYN, B.Sc., Dr. Med. Vet. Vienna, D.V.Sc., Head of the Department of Pharmacology and Toxicology, Onderstepoort Laboratories, Transvaal. London: Gordon and Gotch, Ltd.; South Africa: Central News Agency Ltd. 1934. Pp. 631. £2 7*s.* 6*d.*

ONE of the chief difficulties confronting the veterinary toxicologist is the fact that our knowledge of the active principles of plants and of their pharmacological action is limited to the relatively small number of species used in medicine or cultivated or exploited for other purposes. This work is thus welcome, for it collects under one cover much data concerning the South African flora which is known to be particularly rich in poisonous plants of potential danger to cattle and other browsing animals. The study of plant poisons is complicated by the fact that the toxicity of a plant may be influenced by the soil and climatic conditions under which it is growing, quite apart from the fact that many plants only secrete their poison in certain organs and at certain stages of their growth. Further, the susceptibility of different animals to the same poison varies considerably, and the tolerance of an individual animal may be influenced by its colour in cases of photosensitisation. Added to this is the fact that some plants such as Sorghum or Lathyrus, which are recognised fodder crops, may become toxic under certain climatic conditions or if fed in large quantity.

The general principles indicated above are dealt with systematically by the author, together with such subjects as the diagnosis and prognosis of plant poisons, the eradication of poisonous plants and the prevention of plant poisoning, and the reasons for negative or positive results in experiments with suspected plants. Then follow sections on poisonous foodstuffs, photosensitisation, food rashes, and fungi in relation to health in man and animal. The major portion of the book is, however, devoted to the section entitled Poisonous Plants, which provides a systematic description, with many illustrations, of the various toxic plants, giving their names in English and Afrikaans and very frequently also their native names, together with an account of the active principle, where known, and the symptoms, treatment, and post-mortem appearance of the victim. The inclusion of a large number of references enhances the value of the book, making it of interest not only to those concerned with South African veterinary problems but to workers in all parts of the world.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

III.—INHERITANCE OF MENTAL DEFECT

THE rôle of heredity in the causation of mental defect has long been a fertile source of controversy. During the last few years two aspects of the problem have especially been discussed: (1) How is mental defect transmitted? (2) How much mental defect is hereditary? The first question is mainly biological and has no immediate sociological importance; the second has important sociological implications.

HOW IS MENTAL DEFECT TRANSMITTED?

Fifteen years ago, when Mendelian principles were being applied wholesale to the transmission of all human infirmities, it was commonly stated that mental defect in general was the product of a single recessive Mendelian factor or gene. This view has been substantiated in respect of two rare types of amentia, amaurotic family idiocy[1] and a type of defectiveness described by Sjögren in a circumscribed area in Northern Sweden.[2] Here it was shown that 52 cases, occurring in 34 families, were all related to each other. The demonstration of consanguineous marriages in the ancestry is important in establishing that a rare abnormality is the product of a recessive gene.

But so far as the bulk of mental defect is concerned, it is now certain that this hypothesis does not hold. It does not, however, follow that, because the inheritance of an abnormality does not accord with simple Mendelian ratios of dominance, recessivity, or sex-linkage, the mode of its transmission does not conform with Mendelian principles. The fact has frequently been noted that mental defect occurs, apparently haphazard, in pedigrees wherein appear an excess of other abnormalities such as insanity, epilepsy, psychoneurosis, alcoholism, and sometimes suicide. To account for this so-called polymorphism, the doctrine of blastophthoria* or germ vitiation has been advanced. According to this, the gametes are exposed to damage from toxins or other noxious agencies which, while not impairing their viability, are capable of producing "polymorphic" abnormalities in later generations. This view derived much support from the papers of Stockard[3] according to which the descendants of alcoholised guinea-pigs exhibited weakness and deformities up till the fourth generation as compared with control litters. His experiments were, however, repeated later by Durham and Woods[4] with entirely negative results. But Stockard's findings provided propagandist ammunition though inclined to be dogmatic, are always shrewd and to the point. Of outstanding interest is the description by Dr. A. B. Duel of 12 cases of facial palsy operated on by the method developed by Sir Charles Ballance and himself; this consists in placing an autoplastic nerve-graft in the exposed Fallopian canal, and his description of the technique is so clear that it may be undertaken by any aural surgeon. He contends that the operation should be performed whenever facial palsy follows immediately the mastoid operation, and that a suitable graft introduced without delay gives assurance of a quick recovery. The abstracts cover a very large field, and this year's volume, like the former numbers, is a valuable work of reference. A good index of authors and of subjects is supplied.

[2] Idem: Acta psychiat. et neurolog., Suppl. II., 1932.

* The term blastophthoria was first used by Forel, and is in many respects unsatisfactory. The word βλαστός means a shoot or sucker; also a child. It therefore *suggests* a somatic structure rather than a germ cell, and this implication is borne out by its use in such words as blastoderm and erythroblast. The word φθορία means corruption or mischief. The word blastophthoria therefore implies an agency which damages the fœtus rather than the germ cell. The word has suffered from being written by many psychiatrists as "blastophoria." To leave out the "th" is a solecism equivalent to omitting it in such words as diphtheria or ophthalmology, and indeed entirely changes the meaning of the word. The word phoria, as in euphoria, is derived from φέρω, I bear, and the word blastophoria, as commonly used, should therefore mean the process of carrying something embryonic, as does the pregnant uterus. Psychiatry would suffer no harm if the word were dropped altogether.

The inclusion of a large number of references enhances the value of the book, making it of interest not only to those concerned with South African veterinary problems but to workers in all parts of the world.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

III.—INHERITANCE OF MENTAL DEFECT

THE rôle of heredity in the causation of mental defect has long been a fertile source of controversy. During the last few years two aspects of the problem have especially been discussed: (1) How is mental defect transmitted? (2) How much mental defect is hereditary? The first question is mainly biological and has no immediate sociological importance; the second has important sociological implications.

HOW IS MENTAL DEFECT TRANSMITTED?

Fifteen years ago, when Mendelian principles were being applied wholesale to the transmission of all human infirmities, it was commonly stated that mental defect in general was the product of a single recessive Mendelian factor or gene. This view has been substantiated in respect of two rare types of amentia, amaurotic family idiocy[1] and a type of defectiveness described by Sjögren in a circumscribed area in Northern Sweden.[2] Here it was shown that 52 cases, occurring in 34 families, were all related to each other. The demonstration of consanguineous marriages in the ancestry is important in establishing that a rare abnormality is the product of a recessive gene.

But so far as the bulk of mental defect is concerned, it is now certain that this hypothesis does not hold. It does not, however, follow that, because the inheritance of an abnormality does not accord with simple Mendelian ratios of dominance, recessivity, or sex-linkage, the mode of its transmission does not conform with Mendelian principles. The fact has frequently been noted that mental defect occurs, apparently haphazard, in pedigrees wherein appear an excess of other abnormalities such as insanity, epilepsy, psychoneurosis, alcoholism, and sometimes suicide. To account for this so-called polymorphism, the doctrine of blastophthoria* or germ vitiation has been advanced. According to this, the gametes are exposed to damage from toxins or other noxious agencies which, while not impairing their viability, are capable of producing "polymorphic" abnormalities in later generations. This view derived much support from the papers of Stockard[3] according to which the descendants of alcoholised guinea-pigs exhibited weakness and deformities up till the fourth generation as compared with control litters. His experiments were, however, repeated later by Durham and Woods[4] with entirely negative results. But Stockard's findings provided propagandist ammunition themselves indicated the difficulty of choosing the ideal scheme. Several important points were nevertheless brought out in the discussion.[1] In the first place none of the speakers was satisfied to rely solely on the time-honoured mercury in the treatment of congenital syphilis. It was agreed that although the symptoms may clear up quite readily under its influence, the improvement is often followed by relapse, both clinical and serological. Of single drugs the best on the whole are arsenobenzol derivatives which may be given either intravenously or intramuscularly. Very good results can be got with these, but their effect is quicker and more lasting if they are used in conjunction with (or alternating with) bismuth, preferably in the form of bismuth oxychloride. This combination has proved very efficacious and toxic effects are rare in infants and children. Dr. NABARRO also mentioned cases treated with arsenic by mouth in the form of Orasan or Stovarsol, and was able to report good results, although not yet prepared to describe them as cures. Should this method prove adequate there is no doubt that in many centres it will soon replace treatment by injection, as it seems to have done already in some continental clinics. The main disadvantage is that this remedy, like mercury inunctions, is administered by the parent and may not reach its destination in exactly the quantities prescribed; whereas injection of drugs at a clinic ensures that they will do so.

[2] Idem: Acta psychiat. et neurolog., Suppl. II., 1932.

* The term blastophthoria was first used by Forel, and is in many respects unsatisfactory. The word *βλαστός* means a shoot or sucker; also a child. It therefore suggests a somatic structure rather than a germ cell, and this implication is borne out by its use in such words as blastoderm and erythroblast. The word *φθορά* means corruption or mischief. The word blastophthoria therefore implies an agency which damages the fœtus rather than the germ cell. The word has suffered from being written by many psychiatrists as "blastophoria." To leave out the "th" is a solecism equivalent to omitting it in such words as diphtheria or ophthalmology, and indeed entirely changes the meaning of the word. The word phoria, as in euphoria, is derived from φέρω, I bear, and the word blastophoria, as commonly used, should therefore mean the process of carrying something embryonic, as does the pregnant uterus. Psychiatry would suffer no harm if the word were dropped altogether.

[4] Durham, F. M., and Woods, H. M.: Med. Res. Coun., Special Report No. 168, 1932.

The question how much treatment is necessary for cure is still in debate. Dr. NABARRO is prepared to give the minimum necessary to render the patient free from symptoms and serologically negative, provided he is certain of being able to keep the case under observation several times a year, at least until puberty. If this is not possible it is advisable, he thinks, to continue treatment vigorously for at least two years, irrespective of the clinical condition. It was also pointed out in the discussion that it is wise to be guided by a precipitation reaction of the blood, such as the Kahn, rather than by the Wassermann reaction, which usually becomes negative first. A routine examination of the cerebro-spinal fluid is highly desirable in all cases, whether they exhibit nervous symptoms or not. Those with a positive C.S.F. reaction should be treated with Tryparsamide intravenously and bismuth intramuscularly, and if this is done only the more severe ones will require malariotherapy. The late Dr. DAVID LEES reported excellent results with this routine, and also favourable results in about 30 per cent. of juvenile general paralysis cases treated with malaria.

Finally it cannot be pointed out too often that the ideal approach to the problems of congenital syphilis is by way of prevention—by detecting the syphilitic mothers and treating them adequately during each pregnancy. By this means it can be made almost certain that the child will be free from the disease at birth; or if not entirely free that it will be so little affected as to be curable in a very short time.

PITUITARY EXTRACT AND BLOOD PRESSURE

OLIVER and SCHÄFER in 1895 reported that the blood pressure of anæsthetised animals rises on injection of extracts of the pituitary gland, and later it was shown that this effect is due to an active principle which is obtainable from the posterior portion or pars nervosa though formed, it is said, in the pars intermedia. The effect of this principle on the blood pressure has now been investigated, both in man and animals, by many workers. In man it seems to have no constant influence, some observers reporting a rise of pressure, and others a fall, after subcutaneous or intravenous injections. The conflict of evidence, however, does not seem to be reflected in any general doubt about its clinical efficacy. As W. M. MOFFATT[1] points out, the statement appears in the latest edition of "New and Non-official Remedies" that the "intravenous or subcutaneous injections of preparations of the posterior lobe are followed by an increase of blood pressure which is maintained over a considerable period"; and manufacturers of these preparations often recommend their use in cases of hypotension and shock with the object of raising the pressure. Similarly they suggest that the drug should be withheld where hypertension is already present.

In his own experience, MOFFATT finds no ground for supposing that pituitary extract ever causes blood pressure to remain at a high level for a "considerable" period. In the investigation described in his paper he gave intramuscular injections of 1 c.cm. of obstetrical pituitrin to 62 persons ranging in age from 8 to 56 years, with initial systolic pressures varying between 82 and 218 mm. Hg and diastolic pressures of 58 to 110. They were observed at frequent intervals for an hour after the injection, and no constant alterations in the blood pressure were found. In many patients there was little or no change; in a few there were conspicuous changes in pressure, but more often a fall than a rise. Over the hour of observation the general trend of the pressure, after an initial temporary rise, was downward. This downward trend was characterised by a fall of the systolic rather than of the diastolic pressure, and consequently a slight constant decrease of the pulse pressure was observed. In general it was found that the higher the initial systolic pressure the greater was the fall following the injection of pituitrin, which suggests that the drug is not necessarily contra-indicated in cases of hypertension. In this connexion MOFFATT raises the question whether in his cases arteriosclerotic changes were more extensive in the peripheral than in the coronary vessels. If so, the constriction produced by pituitrin would be greater in the coronary than in the peripheral vessels, and he propounds this as a possible explanation of the greater fall of pressure in hypertensive cases.

Using the preparation known as infundin, B. SACKS,[2] in 1924, found that a small but distinct elevation of the arterial pressure was the rule, the maximum occurring about one minute after intravenous and three minutes after subcutaneous injection. In none of his cases was there a fall of pressure that could be attributed to a direct action of the drug, and during the hour of observation after injection no fall of pressure took place. Contrary to what was noted in MOFFATT's cases there was more often a change in the diastolic pressure than in the systolic; but in both series the pulse pressure—the difference between systolic and diastolic—was reduced. The contradictions of the two sets of observations perhaps may be explained by the fact that MOFFATT used pituitrin and SACKS infundin, both of which are posterior lobe extracts but prepared by different manufacturers. Variation in the effects of injection, both in man and animals, is only to be expected until the hormone has been isolated in its pure form, and in the preparations now available there are probably small quantities of other active principles which have some effect on the blood pressure. It is also of some practical importance to note the possibility that anæsthetics modify the action of the drug. C. M. GRUBER[3] in 1929 found that vasopressin and pitressin caused a rise of pressure in dogs anæsthetised with chloral but a fall in those which had no anæsthetic. A series of subsequent papers[4] from McGill University tends to confirm this observation—in so far at least as they show that "a fall of blood pressure is the predominating effect of the intravenous injection of pituitary extract in the normal unanæsthetised dog."

The experiments so far described deal with the action of posterior pituitary hormone when injected intravenously or subcutaneously, but there is already reason to believe that physiologically posterior pituitary hormone is secreted into the cerebro-spinal fluid. This is important, for HARVEY CUSHING has shown (1931) that the hormone, when injected into the ventricle, produces effects which differ from the effects of subcutaneous injection. Recently H. HELLER[5] has produced convincing evidence that when pituitary hormone is injected into the cisterna magna of unanæsthetised dogs there is a marked increase in blood pressure which he has shown to be of central and not of peripheral origin. It may well be that physiologically pituitrin influences blood pressure mainly by its action upon the vasomotor centres, and that the changes in blood pressure after subcutaneous injection are of pharmacological rather than of physiological interest.

ANNOTATIONS

SPA TREATMENT

THE accounts in the medical and especially the daily press of the recent conference at Harrogate have been of a character that should be very encouraging to the British Health Resorts Association, a body which has not received the attention from the medical profession which it merits. Speaking at the dinner given by the Harrogate Medical Society to delegates from the Association who were attending the conference, Lord Meston, the president, made an important point when he said that the receipt by British spas of State subsidies was not being sought. Many, if not most, continental spas receive such assistance, and having regard to the large sums of money that are expended at these centres by foreign visitors no doubt the policy can be justified; but in this country medicine is more shy of receiving money from any source where other than therapeutic grounds might influence the allocations. Municipal and medical endeavour at each locality, it is held, is often likely to result in scientific treatment; but more than one speaker at the Harrogate conference, as at previous conferences, indicated ways in which local interests might be at variance with regimented treatment. The British patient on his home soil is not taken over, as it were, by his medical advisers and subjected to the course of beneficent dictation, especially with regard to diet, to which he has to submit in many places abroad; and while this suits the national temperament, and no harm should result where the patient is obedient and self-controlled, there is always a risk lest opportunities provided by residential hotels or lodging-houses should tempt the more pliable invalid to treat the therapeutic spa too much as a focus of diversion. The blame here is often laid upon the wrong shoulders, for it is the medical men who have dwelt with such insistence upon the benefits to the sick not only of change of air and environment but also of amusement. The remedy lies in the hands of the doctors, and several speakers at the Harrogate conference pointed to the direction which it should take. There should be close coöperation between the municipal officers and hotel managers and the doctors, all concerned combining to regulate the patient's life exactly in accordance with the attempts to cure or to relieve his condition. This will become easier as British spas develop the intent to specialise in their objects, and to become centres for the treatment of the particular cases found to be most amenable to the natural resources of the health centre. Colonel W. Byam, chairman of the medical advisory committee of the B.H.R.A., described as one of the first duties of the Association the diffusion of information obtained from local conferences, and that procedure will become more valuable as the information grows more precise. What many members of the medical profession want to know are the reasons for believing that patients of a certain class will be well advised to resort to spas possessing certain resources.

THE FILTERING CAPACITY OF LYMPHATIC GLANDS

FILTRATION by lymphatic glands has long been a commonplace of medicine. Investigations on the lymphatic system made by Prof. Cecil K. Drinker and his colleagues during the last three years at Harvard University have made clearer its mode of action and its marked efficiency. As to the former, Drinker, with George B. Wislocki and Madeleine E. Field,[1] showed that when, by the technique which they have perfected, a lymphatic gland of a heparinised dog anæsthetised with nembutal is perfused through its afferent lymph vessel with dilute Indian ink, the retention in it of these microscopic particles is almost complete. Section of the gland shows that the walls of the marginal or cortical and of the intermediary sinuses, and the reticular fibres which cross and recross them, are studded with these minute particles. Some of Dr. Drinker's sections displayed at a meeting of the Royal Society of Tropical Medicine and Hygiene last November showed in striking manner the effects of this spider's web quality. The efficiency of this filtering capacity has since been measured in a number of animals by Drinker, Field, and Hugh K. Ward,[2] using either red corpuscles or hæmolytic streptococci. Their technique is such that they can isolate the afferent and the efferent lymphatic of the popliteal gland of a dog without interfering with its blood-supply, and run through it a measured quantity of an even and standardised suspension of the test fluid at a pressure which their earlier work has shown to be within normal limits, that is to say, those which obtain under passive movements of the limb. From their numerous experiments they have reached the opinion that lymph entering a gland passes as readily through the intermediary sinuses as it does round the marginal sinus; in other words, much of the lymph which reaches the efferent vessel has passed through the gland, and has not merely skirted it by way of the marginal sinus as M. Nordmann has suggested it does. Measured numerically, by counts of red corpuscles or of the streptococcal colonies grown by plating the fluids of the afferent and efferent lymphatic vessels, it appears that when the pressure of entering lymph was less than 30 mm. of mercury, only one corpuscle in 200 escaped through the gland, while no colonies appeared in the efferent fluid even when the entering fluid contained 30 million streptococci per c.mm. Their results show how excellent a filtration arrangement, even before biological reaction begins, is this relatively huge sinus space with its wide and irregular paths and its multitude of baffles. But the perfection of that mechanism depends largely upon persistent quiet and rest, for even very gentle massage of a gland which is perfused with red corpuscles results in the appearance of large numbers of these in the effluent. Here then is experimental proof of the essential need to insist on immobility from the beginning of septic inflammatory conditions. The writers add that their facilities have not permitted them to test the filtration of microfilariæ, but that their results with red corpuscles suggest that the much larger microfilariæ would have great difficulty in passage; accordingly they hope that their paper will induce workers within the tropics to test this point. That should certainly be undertaken without delay. Nevertheless it will be disappointing and a marked loss to medicine if the operative skill and experimental experience available in the Harvard laboratory cannot obtain the means to try out a point so important in the pathology of Bancroftian filariasis.

EFFECT OF METALS ON BONY REPAIR

SURGEONS with some experience of fractures are aware that plating of the fragments may result in defective repair. Occasionally there is complete failure of union with formation of a false joint; more frequently there is simple delay; often there are signs of a rarefactive process, the screws become loose, the fragments become displaced, and the advantage of accurate apposition is lost. These effects happen when there has been no discernible fault in operative technique and no infection. A number of experiments on animals to study the effect of metals on the growths of new bone have been made, but nearly all these have been unsatisfactory because they have been performed under conditions with too many uncontrolled factors. In a recent publication G. Menegaux, P. Moyse, and D. Odiette report[1] their experiments to elucidate this problem. Maintaining that it is a purely cellular problem, they have tested the influence of different metals on the growth of fibroblasts and osteoblasts in vitro. All the experiments were made upon chicken tissue grown in plasma by the ordinary routine methods of the laboratory. Taking precautions to make the conditions of the experiment as uniform as possible, they found they could classify metals into three groups: those that seriously interfered with growths of cells, those that had a slightly inhibitory effect, and those that had apparently no influence upon the growth and life of the cells. It is of great importance to note that the metals grouped as very toxic are just those which are commonly employed in bone surgery—namely, soft steel, iron, and aluminium bronze. These metals produce great inhibition of growth of cells in artificial culture. Of medium toxicity may be mentioned nickel and certain aluminium alloys. Non-toxic metals were found to be gold, aluminium, lead, and some of the new stainless steels. There may be, and are, objections to transferring the results of experiments under such artificial conditions to those in the living body; yet the test was a severe one, for the life of cells in culture where the products of metabolism remain to exert their harmful effects is more precarious than those whose circulation is intact, and more likely to be injured by metals than the cells under the more favourable conditions of life in the body. These researches certainly seem to indicate the advantages of stainless steel, which many surgeons have come to realise from experience, especially in the treatment of fractures in the neck of the femur. Nails were shown by Delbet and others to delay or prevent union. The success of the stainless steel Smith-Petersen type of peg may be due largely to the material of which it is made.

THE TRAINING OF PUBLIC HEALTH NURSES

IT is estimated that there are at present some 20,000 public health nurses employed in the United States by approximately 5000 organisations. Roughly one-third of these nurses work for "voluntary" organisations—i.e., they are not under governmental administration. The other two-thirds are under the direction either of official educational authority or under departments of public health. In 1912, when there were some 3000 public health nurses already in the field, a professional organisation, the National Organisation of Public Health Nursing, came into existence. Since then this central group has been engaged in coördinating experience, formulating standards and criteria of performance, and in general working for improvement both in the opportunities to be sought and the ability to make use of them. In 1931, aided by a grant from the Commonwealth Fund, the organisation undertook a survey of a cross-section of the public health nursing profession. The results of this survey have just been published.[2] The survey was made in 28 communities, rural and urban, in all sections of the country. The distribution of the public health nursing service was found to be very uneven, having little or no relationship either to need or to potential capacity to pay for nurses. The most common ratio of service was one nurse per 3000 to 4000 population, but the surveyors do not consider this an ideal index since it is too inflexible and is based upon actual rather than planned conditions. An interesting recommendation is that official services should be supported by "advisory committees" composed of laymen and laywomen who are interested in the work of the nurse. They are to interpret to her the anxieties and the needs of which the community is conscious; while she explains to them the needs which are apparent to her and the means by which they may be satisfied. In this way false economy in the curtailment of essential health service can be to some extent prevented. In the opinion of Dr. Livingston Farrand, who writes a foreword to the report, its most important feature is the evidence supplied of the great immediate need for improvement in the preparation of the public health nursing personnel. The defects of the present system of training are said to be specially noticeable in the inadequacy of public health nursing service among school-children. It is shown that most nurses have little or no contact during their professional training with healthy children after the period of infancy; and they come to public health nursing with relatively little knowledge or understanding of the health problems of the children of this age-group. The nurse should therefore have post-graduate training in public health and properly supervised experience in those duties of a public health nurse which are not a part of an ordinary hospital training. It is not only in the United States that an impression is growing that the preparation of the public health nurse for her important duties is inadequate, and the qualifications suggested by the National Organisation of Public Health Nurses for future candidates for this service have more than local interest.

THE INCIDENCE OF DIABETES

In a further study[1] of diabetes mellitus by Elliott P. Joslin, Louis Dublin, and Herbert Marks, the magnitude of the problems involved is indicated by means of calculations of the probability of dying from this disease and of the number of cases existing at the present time. On the basis of the death-rates experienced in the United States in 1930 it is found that 15 white males per 1000 born and 27 females per 1000 will eventually die from diabetes. In both sexes the probabilities based upon these 1930 death-rates are at every age appreciably higher than those given by the death-rates of 1920—in fact for females the increase is of the order of 50 per cent. at each age. For both sexes the risk increases slowly to a maximum at 50–55 years, shortly after which other causes exact a greater toll and a rapid decline in the diabetes risk is apparent till the end of life. With such death-rates, over two and a half million persons, or 2·08 per cent. of the population living in the United States in 1930, may be expected to succumb to diabetes—i.e., if the current mortality experience continues to prevail. The present incidence in the United States is estimated to lie between 300 and 400 thousand cases at any one time. A closer scrutiny of the mortality experience suggests that the disease is more prevalent and is increasing faster in urban areas than in rural areas. Racial differences can be only roughly assessed, but using material from New York State and Pennsylvania it was found that the Teutonic peoples suffered more frequently than the Latins, while statistics confirm the clinical observations of an excessive frequency amongst Jews. The Irish, who in Ireland have a low death-rate, show a relatively high rate in the United States, a paradox which the authors attribute to two factors—the higher level of prosperity among the Irish in the States and the disproportionate number engaged in the liquor trade. The occupational mortality statistics of England and Wales have revealed the abnormally high diabetes mortality of persons engaged in this trade (inn-, hotel-keepers, publicans), their rate in 1921–23 being nearly three times that of all occupied and retired males and the highest recorded for any large occupational group. Taken as a whole, the Registrar-General has shown, diabetes mortality varies directly with social status, decreasing with each successive broad grade of social standing. Rates below average are found both in this country and in the United States amongst farm workers and miners, and the incidence appears to be generally low in persons engaged in occupations requiring hard manual labour.

It is well known that the war period 1914–18 was marked by considerable declines in diabetes mortality. This improvement was not confined to the belligerent countries but was, at least to some extent, apparent amongst neutral populations. With the diversion of physicians into military service less complete diagnosis may have played some part in this fall, but it seems likely that restricted food-supply was an important factor. On the other hand, no decline in mortality has accompanied the severe world-wide depression, but as Joslin, Dublin, and Marks point out, the effects of economic crises are not clear-cut. The prices of foodstuffs may drop as rapidly as the rest and the fall in the consumption of food may not be large. The consumption of sugar, judging by the statistics quoted for various countries, does not in itself appear to be an important factor in the diabetes rate or an explanation of the rising mortality. This paper forms a useful review of some of the statistical aspects of diabetes incidence and mortality throughout the world. In their next paper the authors propose to discuss the way in which they believe the external forces influencing diabetes must operate.

COLLAPSE THERAPY IN PNEUMONIA

Some time ago Dr. J. J. Coghlan gave an account[1] of a series of cases of lobar pneumonia treated at St. Olave's Hospital, Rotherhithe, by artificial pneumothorax. He suggested that the separation of the inflamed pleural surfaces relieved pain and facilitated respiration, while the partial collapse limited the flow of blood through the lung. In his hands the induction gave rise to something very like a normal crisis; profuse perspiration set in almost as the needle was withdrawn, cyanosis and dyspnœa were relieved in 15–30 minutes, defervescence occurred in two or three hours, and the appearance of acute distress was lost. It was found, however, that control of the pneumonic process was only temporary. Of the six cases reported, three were young adult males of whom two recovered, while the third had some recrudescence of old tuberculosis in the opposite lung. A fourth case was relinquished for reasons apart from the pneumonia. The fifth was that of a child of 9, so ill on admission that she was not expected to live through the night, who recovered. The sixth was an elderly male with myocardial failure, who was given an exceptionally large fill of 750 c.cm. as a last resort and who died, probably in spite of treatment. Coghlan's experience was novel in this country, although there were continental records of 27 cases so treated by clinicians since 1921, and his work led to some further tests in China and Mexico, a total of 50 cases in all. Dr. L. M. Lieberman and Prof. S. S. Leopold, of Philadelphia, summarise[2] all the results. The ages ranged from 6 weeks to 62 years. In 41 the pneumothorax was instituted between the second and tenth days; in the remainder so late as to be regarded as treatment for complications, rather than for the attack itself. The number of fills averaged two, the amount of air injected at a time 400 c.cm. for adults. In the entire group 47 patients recovered and 3 died. "Despite these almost incredible reports in the literature" (to use their own words), Lieberman and Leopold were unwilling to treat patients themselves without first studying the problem in animals. Accordingly they injected 36 dogs with virulent pneumococcal strains, types I. and II., into the lower-lobe bronchi by means of the bronchoscope. Half the animals were treated by artificial pneumothorax, half reserved as controls. Observations on the course of the disease included clinical study, daily leucocyte determinations, blood cultures, and X rays. No other treatment was employed. In the untreated group 5 recovered, whilst in the 13 others the disease progressed to a fatal termination; in the pneumothorax group there were 15 recoveries and 3 deaths. These experimental results confirm the clinical evidence that collapse therapy produces a picture, temporarily at least, comparable to the crisis in lobar pneumonia. In the experimental animal there seemed also to be a favourable effect on the blood-stream invasion. The Philadelphia observers do not offer any explanation for the modus operandi of this method of treatment. They do not recommend it as a routine treatment of pneumonia, but believe it may have a place in the treatment of selected cases of unilateral pneumococcal lobar pneumonia if due regard be had for the danger of circulatory depression. They agree with Coghlan that lobar pneumonia is emphatically not the disease in which to acquire experience in the technique of artificial pneumothorax.

HEALTH IN ICELAND

An official report[3] of public health in Iceland in 1932 reflects the problems of a highly civilised but very isolated community, a third of whose population of 111,000 is centred in a single town, Reykjavik. But though isolated, Iceland has been involved in the economic world depression, farming in particular having been hard hit by the constantly falling prices of farm products. With unemployment affecting a large proportion of the population, and its economic status at a low ebb, it is remarkable that in the year under review the general health conditions were above the average. Only once before (in 1928) has the general death-rate been so low, and only in two earlier years was the infant mortality lower. Among the causes of death, tuberculosis heads the list as usual (220 deaths). "Old age" comes next with 166, malignant disease with 139, pneumonia with 107, heart disease with 104, apoplexy with 78, accidents with 53, premature birth and debility of the new-born with 27, scarlatina with 17, and nephritis also with 17. Other and unknown causes accounted for 263 deaths. The inclusion of scarlet fever among the ten most frequent causes of death draws attention to the part it has played since it became endemic in Iceland at the beginning of this century. Since then it has reappeared in waves, and has sometimes seemed to be on the point of extinction. The last wave began about the middle of 1930 and has not, apparently, culminated yet. An epidemic of poliomyelitis, with 81 cases and 15 deaths, was the most serious since that of 1924. Cerebro-spinal fever was diagnosed bacteriologically for the first time in 1932, the patient being a child in Reykjavik. Prophylactic measures were at once adopted, and the disease did not spread, but its origin remained obscure. The venereal diseases seem to be on the increase, for the notifications of gonorrhœa have risen from 259 in 1923 to 372 in 1932, and those of syphilis in the same period from 22 to 50. Hitherto syphilis could hardly be regarded as endemic, the vast majority of cases arising abroad; but during the early part of 1932 it assumed the proportions of a modest epidemic in Reykjavik, checked by the end of the year. The responsibility of tuberculosis for nearly one-fifth of all the deaths should be linked with the observation that it often runs a rapid course, with meningitis as the immediate cause of 20 per cent. of the deaths. According to Table IX., 1847 school-children in 14 medical districts have been subjected to the Pirquet test whose proportion of positive reactions ranged from 11·1 to 52·5 per cent., with an average of 33·1 per cent. Tuberculosis in cattle is practically unknown in Iceland. Some years ago a campaign was instituted against favus, the Government paying for the treatment of patients at the Rontgen Institute in Reykjavik. The results have been so good that only one case is now known to exist in the whole of Iceland. Both leprosy and hydatid disease are on the wane, the number of cases of the former having declined from 56 in 1923 to 27 in 1932. The notification of cancer is still very defective; in 1923 there were 95 deaths notified as due to cancer, and in 1932 there were 133 notified deaths from cancer and ten from other malignant disease. Until the last few years, doctors seldom induced abortion. Now increasing pressure is being put on them to do so, and on p. 64 of the report an analysis is attempted of the indications for the curettings and artificial abortions undertaken in as many as 91 cases in hospital. Breast-feeding is the rule from which there are comparatively few lapses. Vaccination is compulsory. What was, perhaps, the most notable feature of public health in Iceland in 1932 was legislation affecting the relations between doctors and patients, and the activities of quacks which are now absolutely forbidden.

SYMPATHECTOMY FOR DYSMENORRHŒA

Since Cotte, of Lyons, introduced in 1925 the operation of presacral neurectomy for intractable dysmenorrhœa and other forms of severe pelvic pain, his procedure, attractive in its simplicity, has almost superseded the older operations upon the sympathetic nerve-supply to the pelvis. Three recent papers testify afresh to its value. J. Soler Julia[1] reports 37 cases of dysmenorrhœa treated in this way. In 17 sympathectomy alone was done, with complete relief in 14, improvement in 1, and failure in 2. Of the remaining 20 patients, 18 also had an appendicectomy or correction of retroversion or both; in 2 peri-arterial sympathectomy of the ovarian arteries was done as well as the presacral neurectomy. Sixteen were cured, 2 were relieved, and in 2 there was no improvement. Julia suggests that in the cases not relieved the whole of the sympathetic supply was not removed, and points out how little is known of the exact paths followed by the sympathetic fibres to the pelvic organs. A. W. Adson and J. C. Masson,[2] whose paper contains a useful summary of the anatomy of the pelvic sympathetic, are also convinced of the value of Cotte's operation for cases of dysmenorrhœa in which the gynæcological lesions found seem to be insufficient to account for the trouble. In the 6 cases they report the results were very encouraging. J. L. De Courcy[3] lays stress upon the need for careful selection of cases, since in hysterical patients no operation is of much value, while if organic lesions are present treatment of these must precede or accompany presacral neurectomy. This author makes it a routine practice to dilate the cervix before proceeding to open the abdomen, and he reports on 21 patients, none of whom failed to get relief. These observations make it evident that presacral neurectomy holds out a good hope of cure in severe cases of functional dysmenorrhœa in which other methods of treatment have failed.

ARTIFICIAL PYREXIA

THE brief survey given in our last issue (p. 1075) of the control of body temperature suggests some remarks on artificial fever. Here a distinction must be drawn between the individual as an entity and the cells of which he is composed. Both are heated and the net result of a rise in temperature must involve many processes. At least three factors may be partially disentangled. First, the natural response of the body is overborne; reflex dilatation of the cutaneous blood-vessels and profuse sweating occur, while presumably the muscles are reflexly relaxed; such attempts at increased output and diminished production of heat are unavailing. Secondly, the passive heating of the cells must increase their rate of metabolism; this is shown by the fact that the body temperature continues to rise after the preliminary heating current has been switched off. Neymann and Osborne[4] estimate that for each degree rise in temperature the basal metabolic rate averages a rise of about 7 per cent., the rise becoming more pronounced as the temperature increases.[1] The reflex reaction is thus annulled by the direct response. Thirdly, the cells of the temperature regulating centre itself must be involved, with what results it is impossible to say. Rabbits have been reported to show a disturbance of temperature control as a sequel to artificial fever. On the whole it is surprising that patients subjected to treatment aiming at generalised pyrexia suffer, according to published results, so little from after-effects; it seems that the temperature regulating mechanism is able to withstand the rough usage. Points of interest are the height to which the temperature can be pushed, and the time during which it may be allowed to remain there. There is little to be gained, however, by discussing these until observers are agreed on the fundamental significance not only of their results but also of their technique. What, for instance, is the nature of the difference between the effects of ordinary diathermy where the electrodes are applied directly to the patient's body, and those of short-wave diathermy or radiothermy where the electrodes are not in contact but the current is induced? Both methods are capable of local or general application, both produce a local or general rise of temperature, and both appear to be useful in chronic conditions and cerebro-spinal syphilis. It is claimed, however, that the short and extremely high-frequency radiothermy waves are also effective in acute conditions where ordinary diathermy is contra-indicated, and that they heat the tissues more uniformly. Their effect, as evidenced by vasodilatation, is said to last for 24 hours. As a basis for rational therapy it is essential to discover how far these and other differences are due to differences in the site (in a microscopical sense) and effectiveness of heat production, and how far to unknown effects of the short waves entirely unrelated to temperature. Claims have been advanced that the short waves have a bactericidal action, are analgesic, and have other specific effects in different diseases and on different cells according to their wave-length. These claims are supported by in-vitro experiments where, to make a sweeping statement for the sake of clarity, one particular wave-length will heat only one of a series of solutions of graded salinity; the capacity for being heated depends on the degree of electrolytic dissociation of the solute. Moreover, the disturbance of heat regulation in the rabbit, previously alluded to, is said to have been accompanied by selective destruction of ganglion cells. Most workers seem to be agreed that electromagnetic waves of less than 30 metres in length have some other effect besides that of heat production.

Until these have been worked out there are good grounds for caution in using the method, particularly for bringing about a generalised extreme rise of temperature. Tissues may differ in their resistance not only to heat, but to some other undefined physical influences. Furthermore, apart from some notable exceptions, such as the *Treponema pallidum*, it is probable that bacteria can withstand heat better than the human body, and it is therefore questionable whether the mere attainment of high temperature is in all cases the objective of choice. It would seem more profitable to explore the effects of this promising form of therapy so as to ascertain what are the specific effects, if any, of different wave-lengths, how far these are referable to stimulation of tissue resistance and hyperæmia, how far to destruction of organisms, and what is the optimum for the affected tissue and the responsible organism in the particular case. The generation of heat, the power of controlling which has up to now captured the imagination of most investigators, might then take its place as an adjunct to treatment rather than an end in itself.

PROFESSIONAL SECRECY

SOME of the problems of professional secrecy have an air of academic casuistry as though taken from a text-book. The problems can be real enough, however, as is shown by the four following cases on which doctors obtained advice from a particular source in the past year. Dr. A. attended the confinement of a girl aged 14½ years who told him that her father was the father of her child; ought he to pass on this information to the police? Dr. B. found that a maidservant's eye was in an infectious condition; ought he to tell the girl's mistress? Dr. C. attended the pregnancy of a patient who was separated from her husband; was it permissible for him to give a report to the husband's solicitors when so requested? Dr. D. found symptoms of arsenical poisoning in a patient who said she had reason to believe that her husband was poisoning her; her food and medicine were examined and arsenic was discovered; ought the doctor to set the law in motion? This group of inquiries is taken from the recently issued report of the London and Counties Medical Protection Society, and in each case the doctor was able to obtain good counsel. Dr. A. was reminded that the information was not of his own knowledge; he was advised that the child or her mother could complain to the police; he was recommended not to volunteer information though his evidence as to the confinement could be given if magisterial proceedings were taken. Dr. B. was advised not to tell the mistress but to suggest to the girl that she should herself do so. Dr. C. was warned to give no report on his patient without her consent; he could tell her of the request and, if she made no objection, he could state that he had attended her in the confinement but should give no report on the case if the patient preferred him not to do so. Dr. D. was told that the rules of professional secrecy might in the circumstances be relaxed. He was advised to get his patient, who lived alone with her husband, out of the house, and then to communicate with Scotland Yard. He did so and a prosecution followed. Such problems show the utility of membership of one of the societies for professional protection which have special experience in these matters. There have been occasions comparable to the circumstances of the second and third of these cases where a false step has involved expensive claims for substantial damages for defamation. In the case of suspected arsenic poisoning the position was different. The doctor owed no particular duty to the husband but was in much the same situation as a doctor who sees his patient's house being burglariously entered.

THE NATIONAL PHYSICAL LABORATORY

THE report[1] of the Laboratory for 1933 contains much of medical interest. On pp. 41–55 radiologists will find new work on the production of X rays and the rating of X ray tubes. A considerable improvement has been found in the X ray output from tubes excited with a constant potential, as compared with tubes excited with a pulsating potential of the same peak voltage. This advantage is more marked with filtered radiation. Work has been continued on the photographic measurement of X ray intensities, particularly for very weak beams. For this purpose considerable improvements have been effected in X ray sensitometry. Correlative work has been done on the X ray absorption of photographic emulsions and their X ray sensitometry. Particular importance is attached to the work done on X ray and radium dosage, the röntgen (r) being now determined to an accuracy of 0·5 per cent. The Teddington laboratory, in conjunction with the standardising laboratories in U.S.A. and Germany and the Hôpital St. Antoine, Paris, is intending to submit proposals for the realisation of X ray standards, and the calibration of X ray dosimeters, to the International Congress of Radiology to be held at Zurich in July. Experiments have also been made with a new form of dosimeter. It is important to notice that the inverse square law is not exactly obeyed for X ray tubes under practical conditions. The investigation of the calibration in röntgens of the therapeutic "B-dose" has now been completed, and an account is to be published shortly. It is found that the number of röntgens per B-dose, as measured by the colour change in a barium platinocyanide pastille, is dependent on the hardness of the X rays used, the value declining to a minimum with increasing hardness and then increasing. It was found that the same results were obtained whether the pastilles were backed with 2 mm. of lead or ½ mm. of aluminium. It is gratifying to note that work has been undertaken on the influence of the wall thickness and the length on the strength of radium needles, and that valuable results have already been obtained. An account is given in the report of an X ray study of tooth structure carried out for the Medical Research Council. As a result of the work, which deals with the structure of the enamel, the different types of enamel can be divided into three classes according to the orientation of the crystals. Two of these are associated with susceptibility to caries, and the other with freedom from the tendency to decay. An invitation to visit the Laboratory on June 26th will give an opportunity to see the basis of this and much other fundamental work. Practitioners will be glad to know that the standard of clinical thermometers submitted for test continues to improve in spite of increased numbers.

INTERNATIONAL MIDWIVES UNION

ASSOCIATIONS of midwives in ten countries and individuals from five others are attending the congress of the International Midwives Union in London this coming week-end. The congress opens with a reception by the Minister of Health at Lancaster House, the discussions taking place at the Midwives' Institute, 57, Lower Belgrave-street, S.W.1. The most important of these is the discussion at 8.30 P.M. on Monday evening, at which Dr. J. S. Fairbairn will preside, when the occupants of six professorial chairs (London, Birmingham, Paris, Lille, Brussels, Budapest) will give their opinion about the best methods of training and educating midwives. Visits will be paid to many of the maternity hospitals and institutions, and the proceedings will end with a farewell dinner on Tuesday evening.

WE regret to announce the death at Belfast on Tuesday last of Mr. Andrew Fullerton, emeritus professor of surgery at Queen's University and consulting surgeon to the Royal Victoria Hospital.

AN appeal is being made, as described in our issue of May 12th, for £105,000 to build a new nurses' home and pay block at St. Mary's Hospital, London. The sum received since March 1st is more than £42,000.

THE Royal Society of Tropical Medicine and Hygiene is holding a conversazione at Manson House, 26, Portland-place, London, W., on Thursday next, May 31st. Fellows and their guests will be received from 8.30 to 9 P.M. by the president, Sir Leonard Rogers, and Lady Rogers. Application for tickets may be made to the secretary at Manson House.

A CHADWICK lecture on the national food-supply and public health will be given by Dr. John Boyd Orr, F.R.S., director of the Rowett Research Institute, Aberdeen, at 5.30 P.M. on Tuesday next at the Royal United Service Institution, Whitehall, London. At 5 P.M. on June 14th Mr. E. A. Bowles will give a lecture in the Chelsea Physic Garden on simples and herbals.

THE series of articles on Prognosis contributed by invitation will be resumed early in June, when publication of the concluding lectures on the Preventive Aspects of Medicine at King's College has been completed.

CRAIG CONVALESCENT HOME, MORECAMBE.—Last week Mr. J. B. Priestley opened the new buildings of this convalescent home for children, named after Mr. Thomas Craig, of Bradford. Since the home was first opened 11,400 children have passed through it. A fortnight's stay has added an average of 2 lb. to the weight of each child.

THE PREVENTIVE ASPECTS OF MEDICINE

A Series of Lectures in progress at King's College Hospital Medical School

XXIII.—THE PREVENTION OF MENTAL DISORDER

It might well be thought that the province defined by the title of this lecture is large enough, but I intend to widen it by including reference to mental defect. Mental defect in the modern sense of the term, as distinguished from mental disorder, may be defined as *arrest* of mental development due to any cause, whether pre-natal or post-natal, and in the latter case operative before the age of 18.

The distinction between mental defect and mental disorder—i.e., anomaly in those who up to the age of 18 have been normal—is entirely a legal one. It is of practical use in ensuring that children with mental troubles of post-natal origin shall be treated with other children whose defect is pre-natal (rather than with adults). But the distinction is not a scientific one from the standpoint of ætiology, and for purposes of prevention as opposed to cure there is little distinction between the problems of mental defect and those of mental disorder. This is obvious in respect of certain organic conditions—e.g., mental troubles due to syphilis or epilepsy, and of gross "functional" psychoses such as schizophrenia.

It is essential to reality that one should emphasise this continuity of defect and disorder. One of our main problems is the degree in which establishment in childhood of faulty habits of reaction are dependent on innate factors and even intellectual ones; on the other hand, it is necessary to consider how far such habits are responsible for later neuroses and psychoses.

Further, I am obliged to deal both with what are termed neuroses and psychoses. Here we have a semi-popular distinction based on legal and administrative grounds. It is a distinction of some slight practical value if used only by those who appreciate its limited meaning, but may be a danger. Some years ago it would have been true to say that psychoses were such mental disorders as in the poor usually led to *treatment* in an asylum under certificate, while the neuroses were those which in the poor were usually not treated at all. Changes in law and language would now compel one to say instead that neuroses are mental syndromes of such form and degree as to be less likely to necessitate legalised treatment. But neuroses are due in varying degree to factors of the same four main groups (see below) as psychoses, and the problems of their prevention are the same. Clearly quantitative distinctions—as that in neuroses previous mental experience plays a relatively greater part in causation; that the affection of the personality is more limited; that insight is apt to be greater; and that psychological treatment of specialised kinds may sometimes be more effective—would not justify separate consideration of the neuro-psychoses and the psychoses; and they cannot even be separated for practical purposes except by contrasting extreme cases of either group.

In taking as my topic mental disorder and defect, I am therefore including all conditions in which anomalies of behaviour and of the consciousness associated with it are a prominent feature. I need hardly say that I am including organic as well as functional mental troubles, since in my view "organic" cases are merely those in which the physical basis is obvious, while "*functional*" are those in which for the present it is obscure. The distinction is one based on ignorance. The prevention of these conditions must still be propounded as a set of problems. No such record of general achievement is possible as in the case of tuberculosis. Little or no statistical evidence is available in support of the efficacy of any measures applied to the individual in preventing the onset of mental disorder.

To judge from statistics, certifiable insanity would seem as little preventable as cancer. Figures seem to indicate that the number of first admissions to institutions for certified insanity has in proportion to the population not materially decreased in the past 50 years. These patients with certified insanity are the sole cases which can be clearly identified, and therefore the only ones concerning which comparison is available.

Despite the continuity which I have stressed between the mental troubles of adult and child, between neuroses and psychoses, between organic and functional, I do not mean that all mental disorder is *one and indivisible.*

For example, there has been a considerable reduction during late years *in the certified admissions* suffering from the specific results of alcohol and syphilis. Owing to former fallacies of diagnosis, exactly comparable figures are unobtainable, but the general conclusion seems certain. But if this is so, then this reduction must be balanced by *increase in the total number* of cases due mainly to other factors. As we are dealing entirely with first certifications, the figures cannot be affected by such *points as altered* standards of fitness for discharge or changes in the institutional death-rate. Nor in London, at least, can any *explanation be based* on an increased proportion of old people. It is true that there is not only an absolute but a relative increase in the number of the old. *Among such there occur* a disproportionate number of psychoses fitting the patient for treatment in an institution, and of late, owing to improving repute of institutions, there has been a steadily increasing tendency on the part of the young to agree to the treatment in hospitals of those *mentally* enfeebled by age. But that would not affect the London figures for certified insanity because the senile mental cases are dealt with apart.

The persistence, almost unchanged, of the incidence of certified insanity is one of the worst facts of medicine.

There has been a vast *improvement* in the conditions under which patients are treated. That we possess the power to alleviate suffering is certain; but whether we can even abbreviate is very doubtful; assertions about the shortening effect of early treatment are full of statistical fallacies. The limited extent to which it is possible to prevent a first or subsequent attack will be discussed later. Any power to eradicate the constitutional tendencies *underlying the major* psychoses is still to seek. The situation is somewhat better as regards the neuroses or minor mental troubles, but the difference is far less than the enthusiasm of some optimists would lead one to believe. Mental prophylaxis is therefore an unsolved problem.

Prevention of any form of disease necessarily involves consideration of the factors giving rise to it. Briefly, in mental disorder or defect of any kind these factors may be placed in four groups:—

(1) Anomalies of innate make-up.

(2) Anomalies of the changes incidental to particular ages or epochs of life.

(3) Exceptional mental experience, whether recent or remote.

(4) Gross physical influences.

The form of every mental process must necessarily be the resultant of factors belonging to all four groups—i.e., heredity, epochs, mental experience, and physical influences. Theoretically only one factor or group might be operative, but in practice this is never so, and it is thus necessary to consider factors drawn from all the groups.

True prophylaxis perhaps should mean measures taken in advance of the occurrence of first symptoms and is theoretically distinguishable from early treatment designed to arrest progress or recurrence. If this distinction is accepted, however, there is rarely an opportunity for individual prophylaxis in the strict sense. Multiple factors are almost invariably associated in determining occurrence of psychoses and neuroses. One of these factors is commonly a long-standing, if not innate, constitutional tendency. As a rule, to eradicate this is beyond one's powers. One's usual goal is reduction of overt manifestations; in fact, the keeping of such in check, either before or after a first attack, may be all that is possible.

Having established the range of conditions to be prevented and the nature of the aim intended by the term "prevention" it is necessary to consider how this can be pursued. As always, prevention must here include *collective prophylaxis* directed towards the interests of the many and *individual prophylaxis* in any case where special risk is anticipated.

Collective Prophylaxis

The essential preliminaries of any progress in prevention of mental disorder are: (1) Education of the whole medical profession; (2) Provision of trained personnel; (3) Research; (4) Provision of suitable institutions.

MEDICAL EDUCATION

On the lack of proper education of the medical profession in regard to mental disorders depends the composure with which they as well as the public view the present incidence of insanity and mental defect.[1]

Of all children born, about 1 in 35 will at some time be certified before death. The number of those for whom at any given moment some sort of legalised special provision has to be made on account of mental disorder and defect approaches half a million. The country is spending about ten millions a year on care of those suffering from mental defect and disorder and less than ten thousand on any research to prevent these.

It is necessary for any progress towards general prophylaxis in England that the mass of the profession who are not specially concerned with mental disorder should have a greatly increased consciousness of the size of the problem and should use their influence to rouse the public. Of late years a steadily growing interest has prevailed among the leaders of the profession, but this interest is not widespread among practitioners.

The general practitioner could hardly be expected to find the time or receive the training to carry out active measures of individual prophylaxis. But he should be trained, as he is in respect of abdominal emergencies, either to recognise the cases that need specialist intervention and where to go for it, or at least where to get a sound opinion regarding the necessity of treatment. It is just as important to recognise the vast number of neurotics in whom intensive treatment is to be avoided as it is to identify those who need it.

TRAINED PERSONNEL

Psychiatrists.—As regards the medical profession, the other requisite is the provision everywhere, for consultation on behalf of the poor, of specialists for whose qualification an official body has vouched.[1]

Psychiatric social workers.—Social workers with special training for the investigation and correction of the setting in which breakdown tends to occur are indispensable to modern psychiatry. Their coöperation not only makes it possible to deal more effectively with the individual, but is also of great value in research.

RESEARCH

Organisation of research is by far the most important need of psychiatry in the near future. Special provision for its endowment was made in the Mental Treatment Act three years ago, but so far the amount spent is ridiculous in relation to the expenditure on the maintenance of even those legally recognised as suffering from mental disorder or defect.

Of late years there has appeared a definite willingness to spend money on treatment of early and minor mental disorders in out-patients and wards apart from the custody of the insane. But the main lack of all such psychiatric clinics is a treatment which is more than palliative, symptomatic, and expectant—i.e., awaiting natural recovery. Perhaps as regards treatment the situation is no worse than in respect of typhoid. As regards prevention in the full sense it is far worse.

Personally, I think that for a generation much interest has been squandered on studies having none of the qualities of science and useless for prevention because calculated at most to elucidate reasons for the form rather than for the occurrence of mental disorder and defect.

SUITABLE INSTITUTIONS

Where should a programme of education, research, and preventive psychiatry be carried out? My view is that in Great Britain, as in all progressive countries of the world, the university psychiatric clinic should be their nucleus. Such clinics should provide for the treatment on a voluntary basis of recoverable cases of mental disorder of every kind and degree. They should deal with children as well as with adults and, of course, with both in- and out-patients. As the public learns to use such clinics, their work will become increasingly preventive.

In their fully developed form as they exist in Germany, Holland, and in the more advanced States of America, such clinics form a part of every university which is attempting clinical teaching of medicine. Excellent pioneer service has, of course, been done in detached out-patient centres and at independent child guidance clinics as well as in general and neurological hospitals. But arrangements for education and research cannot be scattered and multiplied. Moreover, it is impossible to treat within the wards of a general hospital a representative collection of patients illustrating even such a range of neurosis and psychosis as the future practitioner will meet. In the absence of psychiatric clinics English students will presumably continue to be taught psychiatry mainly by a few demonstrations on the chronic insane.

There appears to be no chance that the money needed for thorough organisation of preventive psychiatry throughout the country can be obtained from voluntary sources; it will have to be found by local authorities. Provided that medical opinion has a proper weight in control there seems no disadvantage in this. University psychiatric clinics will presumably have to be municipal institutions, though in close connexion with the general hospital and the rest of the medical school. In non-university centres they should be associated with voluntary or municipal arrangements according to local conditions.

---

[1] In Turkey, under the wise rule of the Ghazi, the law forbids anyone to practise as a specialist in mental disorder unless he has passed the necessary examination after two years of supervised clinical work with patients of all kinds. Perhaps some day England may emulate Turkey in this respect.

COLLECTIVE PROPHYLAXIS OF ORGANIC MENTAL DISORDERS

It is now necessary to deal with the problems of prevention in more detail. As a preliminary to the most convenient mode of discussion of them one must define a little further the meaning of the terms "organic" and "functional." By an organic case is meant merely either one in which an essential physical factor is operative (e.g., alcoholism); or in which during life or after death structural or biochemical change can be detected which is constant and characteristic and not merely the consequence of behaviour; or in which there are bodily symptoms, such as fits, which are independent results of the same process. The distinction between functional and organic, as mentioned, is one based merely on ignorance. It has, however, considerable practical value and in detailed discussion it will be better to forego a strictly ætiological order, and to isolate organic conditions before approaching the still more difficult problems of functional disorder.

In the last report of the Maudsley Hospital 33 independent organic conditions are noted as main factors in various cases among the 10,000 there tabulated. But of these 33 only 6 post-natal factors play a part in as much as 1 per cent. apiece of the total of cases. Two out of these 6 can here be ignored from the standpoint of prevention—viz., senility and epidemic encephalitis, the latter because the disease which is the source of fresh cases is now so rare. The remaining conditions are arteriosclerosis, idiopathic epilepsy, alcoholism and neurosyphilis.

Arterio-sclerosis.—The early occurrence of arteriosclerosis is a problem of general medicine and its prevention needs no special discussion here.

Epilepsy.—Collective prophylaxis of this could only take the form of eugenic measures which have hardly been attempted.

Alcoholism.—There has probably been a reduction of all morbid consequences of drinking, including those psychoses specifically due to its toxic effects, to about one-third of their pre-war frequency. In England this has been a political rather than a medical achievement, brought about by making alcohol dearer and harder to get. The triumph has been won in a contest between boost by the Trade and cost as raised by the State, rather than by precepts. The result is, of course, more satisfactory than prohibition proved in America or is likely to prove in a country with similar political organisation. It is probably less satisfactory than a scheme of State sale such as exists in Sweden and Denmark. There alcoholic addiction of such degree as to produce lasting psychotic effects has been almost restricted to those who would be unmistakable psychopaths apart from its influence, but in England the political influence of "the Trade" would presumably render State sale so unlikely to become a matter of practical politics as hardly to be worth discussion.

Syphilis.—A disproportionate reduction in general paralysis soon after the war was largely due to the death of 800,000 men mostly between the ages of 20 and 40 and naturally including a high proportion of the potential general paralytics of the next ten years. But reduction of incidence of general paralysis goes on and is probably due in the main to decrease in the number of primary infections with syphilis.

There seems some reason to believe that the decrease of primary syphilis may be in some measure connected with the reduction of the vogue of prostitution, but no reason to think that this is attributable to an increase in chastity—rather the contrary. Probably the main factors are two: increased readiness of application for treatment and early abolition of infectivity by arsenical treatment.

COLLECTIVE PROPHYLAXIS OF FUNCTIONAL MENTAL DISORDERS

It is necessary to consider prevention in relation to the main factors determining the occurrence of functional mental disorder without any reference to details of its form.

Heredity.—Exact figures concerning the probability of inheritance of this or that functional syndrome are probably fallacious. Errors may depend on the fact that groups of cases exhibiting the syndrome include a medley of conditions, as in the case of epilepsy. Conscientious selection for research of so-called unmistakable cases may isolate one subgroup in which the transmissible factor is most potent. Published observations concerning the chances of transmission may thus be true for the particular sub-group investigated. They seem too high for the clinical experience of all the cases showing the syndrome. Nevertheless, while it is impossible at present to evaluate exactly the influence of heredity in determining psychoses and neuroses, no reasonable doubt exists that this is great. The conclusion seems distasteful to the omnipotent type of psychotherapist. To the reasonable it is unobjectionable. Innate susceptibility is, of course, only one factor. Other post-natal influences are responsible in varying degree and open to prevention and treatment.

At present there seems little hope of constructive eugenics of any sort likely to influence materially the incidence of mental disorder in a wide sense.

Sterilisation.—The passage of a measure to legalise voluntary sterilisation would be an excellent gesture affirming the claim and the intention of the human race to determine to the best of its ability its own genetics as well as its own environment. Further, permissibility may be of great value in individual cases but not in collective prophylaxis. In this connexion the following points should be noted:

(1) For many reasons legislation can only properly allow voluntary sterilisation. Among other grounds is the fact that it is impossible to define conditions which are always transmissible. Such definitions would be necessary in order that a schedule of groups for the compulsory sterilisation might be tenable scientifically.

(2) Present sentiment would not tolerate eugenic sterilisation being legalised except where the abnormality likely to be transmitted is a very gross one. Any idea that sterilisation as now proposed may help to prevent neurotics and members of the so-called social problem group from breeding their kind is quite misplaced.

(3) Some safeguards are absolutely necessary in the interests of prospective applicants for sterilisation. But any tolerance of the operation will certainly be accompanied by safeguards intended to prevent conception for reasons other than those officially approved. In practice, to get sterilisation legalised at all, it will certainly be necessary to advocate the association of permission with safeguards so numerous as to render any influence on the collective incidence of mental defect and disorder almost imperceptible.

Legalisation of abortion.—For eugenic reasons, even under safeguards like those proposed in connexion with sterilisation, would probably do much more than the latter; many of those whose progeny is undesirable would be far more likely to accept operation and all the trouble connected with it on account of an actually forthcoming child than on account of purely hypothetical ones. But even legalised abortion would never make any wholesale impression on the problems of psychiatry so long as it was only tolerated for eugenic reasons under safeguards. As with sterilisation, this would necessitate its restriction to those with family history of such gross disorder as is proven by certification or similar evidence. The very continuity of minor with gross mental disorder will therefore render eugenic operations of either sort largely ineffective to prevent even these gross deviations, and totally so in respect of the minor degrees of mental defect and disorder. Yet as social problems these minor degrees are really more important than the grosser conditions.

Far more might indirectly be achieved if abortion were legalised for economic reasons. It is conceivable that the community might some day revolt against the view that those who are unable to support themselves have an unlimited title to present to the community offspring which are reasonably certain to be on balance liabilities rather than assets.

Special ages and epochs of life.—General measures to render the special biochemical aspects of any of these epochs less productive of mental disorder do not exist. It is a striking fact that practically nothing is known as to the biochemical changes which no doubt form the common foundation of the mental disorders of pregnancy. The same is true of the puerperium, of the menopause and other epochs, and therefore no general guide to prevention of these exists.

Mental Experience. (*a*) *Psychogenesis.*—In the main child guidance clinics deal *individually* with psychogenesis in the young. But there are many other agencies trying collectively to decrease the stresses which affect the potential patients of these clinics.

The prevailing tendency to emphasise the importance of the impressions of infancy would throw back the critical period to a point when not even a child guidance clinic could directly aid in prevention. This would render the education of prospective parents the sole hope. As one listens to the recitals of the early experiences alleged to produce such dire psychopathic results they seem a little banal. This is equally true whether they are considered on a Freudian or Adlerian basis. Personally I find it hard to accept as adequate such events as removal from the breast before satisfaction or from the stool while lingering over defæcation. Many of the instances of pampering or neglect or of pampering followed by neglect which are cited as explaining neuroses, psychoses and delinquency are trivialities such as have happened to many of us and are obviously insufficient without invoking another and exceptional factor to make them effective. To me it seems likely that the child while impressionable has also far more tendency towards return to the normal than such theories suggest, and that much more persistent influences are necessary to produce lasting effects. This is at least the more hopeful view, implying that the child guidance clinic has a chance to intervene while the mischief is in the making, rather than before it is done and needs such elaborate undoing as must be available for few.

While the child guidance clinic is fully justified by its effect in reducing the actual unhappiness of children, it must be remembered that there is no evidence which could possibly be called scientific as to how far such troubles as it treats are really the precursors of mental disorders in adults. It seems that a large proportion of well-defined adult psychoses, whether schizophrenic or manic-depressive, are wholly devoid of any history suggesting such relation. The connexion is apt to seem more definite in what one may call anomalies of character—including delinquency. But even here it cannot yet honestly be said to what extent any treatment in childhood can really eradicate the tendencies.

(*b*) *Sex experience and sex education.*—To me the Freudian generalisations concerning the universal and specific relation of various clinical syndromes to particular types of sex experience during early childhood seem to be based on inadequate evidence and illogical deductions. But it is possible that exceptionally such experience may so condition a child as to predispose later to the development of one of the abnormalities such as masturbation, homosexuality, or excessive erotism, which with multifarious reactions to such a tendency constitute a source of unhappiness to a good many. As to this, perhaps the first general prophylactics needed are the steady growth of a morality that is rational rather than traditional, honesty among adults, and proper education of the child. From the standpoint of the neurotic it might be a great advance if what is termed morality could be made a question of manners, and departures from it were regarded rather as crudities than as sins. Those at least who are happily married will not regard monogamy as needing enforcement by terror. There is good reason to believe that in Russia in a generation brought up entirely as agnostics and in a milieu where premarital chastity is treated as a matter of taste, the large majority of girls at least are virgins on marriage, and the greatest possible freedom of divorce leaves it still quite exceptional.

The knowledge of the frequency of masturbation in both sexes and the consequent absurdity of ascribing to it the physical and mental disorders formerly used as bogies is now widespread among doctors, but such terrors still play a large part among neurotics and psychotics of many types.

Homosexuality, though far less frequent than masturbation, is fairly common in both sexes. In a majority perhaps it depends merely upon opportunity and is transient. In others where strong attachment to a homosexual object (or other perverse tendency) is formed during the first consciousness of sex feeling, the perversion seems more likely to persist. But it may well be that such persistence only occurs where much earlier conditioning or innate disposition exists. It would be interesting to know from a standpoint of prevention the relative frequency of transient or lasting homosexuality on the one hand in co-educational and on the other in ordinary schools, but I know of no reliable statistics bearing on this question.

Individual Prophylaxis

Space forbids anything but the most cursory reference to individual prophylaxis, which can be considered under the same headings as collective prophylaxis.

MENTAL DEFECT

If, as I stated earlier, checking of progress and consequence of a primary disability can legitimately be brought under the term "prevention," then a good deal can be done in mental defect. It is apparently a proven fact that among aments whose defect is not severe enough to need an institution, those who have been brought up at special schools or under statutory supervision are far more stable in every respect. They are less prone to emotional storms, hardly ever become criminal or immoral, and are probably less prone to the supervention of an acute psychosis upon the defect. In view of all this, strict ascertainment of aments outside institutions and their suitable upbringing is essential. It is a pity that recently, with a view to "economy," the Government has directed that no more places in special schools are to be found and that ascertainment of defectives has been discouraged.

ORGANIC MENTAL DISORDERS

There is little or nothing to be said or done about averting or arresting mental symptoms in those liable to them through *old age, arterio-sclerosis,* or *epidemic encephalitis.* With regard to the last, drugs such as hyoscine, which relieve the motor symptoms, have little influence on mental sequelæ of any kind. To some extent the same is true of luminal in epilepsy. Its effect in checking motor convulsions is greater than in averting petit mal attacks or paroxysmal mental attacks. But luminal may slow the sort of deterioration which is apt to develop especially in the young when motor fits are very numerous. On the other hand the liability of heavy dosage with bromide to increase this should never be forgotten.

General paralysis.—Measures directed to reducing incidence of syphilis have been discussed under general prophylaxis. So far as I know little has been done with regard to the special problem of averting nervous sequelæ in those known to have suffered with syphilis.

Alcoholism.—Personal prophylaxis against alcoholic psychosis means early cure of addiction in those in whom it has arisen. With regard to this the position is deplorable. Personally I disbelieve entirely in all treatment outside an institution, whether psychological or by drugs, except in the very rarest instances. There are no special institutions for the poor and some at least of those catering for the self-supporting are expensive but unsatisfactory. I believe that there will never be progress without a change in the law. The modern tendency is towards treatment on a voluntary basis wherever possible, but such a method seems futile in established addictions. The provision whereby an addict could legally bind himself to remain under treatment voluntarily but for a minimum of several months seems to be falling into disuse. Considering the havoc which alcoholics play with the lives of others as well as their own the law should provide that on a second occurrence of incapacity from alcoholism requiring medical treatment commitment to an institution for a suitable period should follow regardless of certifiability.

INDIVIDUAL PROPHYLAXIS OF FUNCTIONAL MENTAL DISORDERS

Heredity.—While there is little hope that the collective prevalence of functional mental disorders in the community will be much checked by such steps as the legalisation of eugenic sterilisation or even of abortion, there is more hope for the growth of at least a family conscience that will make members of stocks in which there is concentration of neuropathic heredity more chary of reproducing their kind. There seem no reasons why they should be denied marriage, intercourse, or the permanent security that this will be infertile which they desire and which sterilisation will give.

Epochs.—Perhaps the main item worth discussion here is prevention of mental disorder arising during pregnancy, during the puerperium, or from subsequent responsibility for the child. One should include here aggravation of pre-existing disorder. Quite apart from any question of eugenic intervention on account of expected quality of offspring, there is no clear definition in law as to what justifies the production of abortion in the interest of the mother. It is perhaps inadvisable to attempt definition but the standard in practice is becoming more liberal. Perhaps this tendency will grow as the right of the law (which has given up the campaign against contraception) to force a woman who has conceived to bear a child she does not want begins to seem less axiomatic.

Mental experiences.—Personally I disbelieve in all constant psychological situations as the specific cause of particular clinical syndromes. On the contrary, I believe that every syndrome in so far as isolation is justified at all corresponds to a reaction-pattern of the organism, each of which can be impaired, released, or overactivated for a multitude of reasons, some "functional," others "organic" as above defined.

Among such reasons are all situations which in humanity can cause disturbing emotions. This disposes of the question of summary rules for the prevention of psychogenetic mental disorders. I would rather suggest some cautious general principles of a negative kind. For all prophylactic purposes psychiatry at present is grossly handicapped by lack of any indicators of susceptibility, whether innate or acquired, whether quantitative or qualitative. It is probable that linked physical characteristics might be more objective and useful, but the characteristics described by Kretschmer do not seem to meet requirements. In the absence of such indicators, great caution is necessary to avoid doing individuals and the community the worst possible disservice by prophylactic enthusiasm.

It is neither possible nor desirable that the community should adapt its requirements and its rewards to the weaknesses of the neurotic. The quest of safety for the neurotic almost inevitably means renunciations, and these renunciations may themselves eventually bring stresses at least as great as those they were meant to avert.

That the danger of fostering neurosis by attempts to prevent it or cure it is a reality is shown, for example, by many cases of war pensioners. I entirely agree with the conclusion reached by Dr. S. A. Kinnier Wilson in an earlier lecture in this series, as to the inadvisability of encouraging neurotics to discuss their symptoms and their causation. For a very large number of neurotics, stoicism is still the best course to recommend.

Much of the talk about encouraging seeking of medical advice upon the first appearance of symptoms is wholly wrong in the case of neuroses, whatever may be true in case of symptoms suggesting possible cancer or tuberculosis. If one could be sure that in a large majority of cases patients would be dismissed with reassurance and encouragement, one would be much more easy about the ultimate result of the multiplication of centres for psychiatric advice. As to the giving of collective counsel upon details of mental hygiene directly to the public by lectures and pamphlets (as opposed to urging resort to expert advice), in view of all the possibilities of misunderstanding and misapplication, it seems to me likely that on the whole this will do more harm than good.

EDWARD MAPOTHER, M.D., F.R.C.P. Lond.,
Physician in Psychological Medicine, King's College Hospital;
Medical Superintendent, Maudsley Hospital.

ST. BARTHOLOMEW'S HOSPITAL.—The report of the treasurer, Lord Stanmore, shows that in 1933 the number of new in-patients was 10,333, a reduction of 476, whose average stay was 21·4 days. At £225,000 there was a net decrease in income of £243; on the other hand, the expenditure—£194,000—fell by a fraction over £3000. By arranging for old and new cases and male and female patients to attend at different times much unnecessary waiting has been saved to out-patients, who numbered 90,311. Some remarkable figures are contained in the pharmacist's report. In 1913 there were consumed (fractions omitted) 235 gallons of brandy; in 1933 the quantity was 11. Port fell from 216 to 4 gallons; whisky from 1¾ gallons to nil; burgundy from 9¼ to less than 1¾; and quarter-bottles of champagne from 155 to 17. Particulars are given of the sale of a small farm in Kent which had produced a net annual income of £5; the invested purchase money yields over £32. In the year ended with July, 1933, there were 964 students attending the medical college. The nursing staff now numbers 404, and of 91 entrants for the first year examination of probationers 84 passed. The Charity Commissioners have sanctioned the expenditure of a sum not exceeding £150,000 for the erection of the new medical block, subject to the replacement of the money in 60 years by means of a sinking fund.

SPECIAL ARTICLES

MUNICIPAL HOSPITALS

In opening a discussion, at the annual meeting on May 13th of the Socialist Medical Association, on the

Present Scope and Future Development of Municipal Hospitals

the president, Mr. Somerville Hastings, said he wondered how many of the Members of Parliament who voted in favour of the Local Government Act, 1929, really appreciated what they were doing. Rightly used it was the key which would open the door to a complete and unified municipal hospital system. The Act, although full of uncertainties and anomalies, did transfer the powers under the poor-law from small local boards of guardians to county councils with an instruction to them to sit down and think out how best to utilise their new powers. As far as the development of hospitals is concerned, no increased powers were given. Section 131 of the Public Health Act, 1875, stated that " any authority may provide for the use of the inhabitants of their district hospitals or temporary places for the reception of the sick," and the only later addition was the inclusion of pregnant women amongst the sick. It seemed curious that until quite recently hardly any use has been made of these powers, with the exception of Widnes and Barry, which provided themselves with accident hospitals, and Bradford, which took over a poor-law infirmary and administered it as a general hospital.

Local authorities had now been set thinking in one of three directions :—

(1) Many authorities had left their hospitals as poor-law infirmaries much as they found them, so that anyone who took advantage of treatment there became technically a pauper. The normal means of securing admission was to apply to the relieving officer for an order, but the medical superintendent could in an emergency admit any patient on his own responsibility.

(2) A few authorities had made a declaration that any assistance provided should be by virtue of the Public Health Act, 1875.

(3) A much larger number of authorities (including London) had appropriated the hospitals and were running them as municipal hospitals under the 1875 Act. The term " appropriation " may need a little explanation. By means of this power a council can take over property or land and use it for any agreed purpose—e.g., providing hospital treatment according to the powers permitted by the Public Health Act 1875.

Before making a declaration (2) the authority had to be certain of sufficient accommodation and facilities ; for once a declaration were made, it would be illegal to treat any sick person in a poor-law institution. If appropriation (3) were decided upon, the commitments were less serious and the advantages still very considerable. In the first place, admissions, except in the case of the destitute, were made by the medical superintendent, the usual method being for the patient's doctor to ring up or write to him explaining the case. It was, he thought, a disaster that under the Act the cost of maintenance and treatment for any disease other than infectious had to be recovered from patients who could afford to pay for it. If the hospital was appropriated, consultation with the Ministry of Health over details of administration was not required, and the authorities had much greater freedom.

In whichever way severance from the poor-law was accomplished it opened enormous possibilities of development, especially in urban areas where the population was considerable and the hospitals not too far apart. Specialisation became possible ; certain wards in one hospital could be set aside for the treatment of cancer by radium and X rays, in another hospital for eye cases ; facilities could be provided for thoracic surgery or bronchoscopic work in a third, and so on. It became an easy matter to transfer patients from one hospital to another or to obtain the services of any type of specialist needed. If a severe epidemic broke out and the isolation hospitals were filled a block of wards, or even an entire general hospital, could be evacuated and used for infectious disease. Municipal hospitals could be used as clearing houses for the observation and sorting out of cases of tuberculosis and for minor operations on school-children.

A local authority could not legally refuse admission to any destitute patient if his medical necessities demanded immediate hospital treatment ; accordingly in calculating the number of beds required, the highest possible and not the average demand had to be kept in mind. Consequently in the summer months a good many beds were vacant which could be used for operations which were not urgent. A consultative out-patient department then became essential. Whether such a department came within the terms of the 1875 Act as " a temporary place for the reception of the sick " was uncertain, and it was still more doubtful whether a local authority had any legal right to make a charge for out-patient treatment. Nevertheless it was essential to develop them at municipal hospitals, and where geographical conditions made this possible it would be convenient to carry out there the tuberculosis, V.D., and child welfare work of the authority. School clinics could be held there, and as far as circumstances permitted, the district medical officer—generally a member of the resident staff—should see patients there. In a word the out-patient departments of municipal hospitals and their branches could be developed into the medical centres of the district.

The unification suggested should prove of value for research and for medical education. Instruction in fevers had long been given in hospitals controlled by local authorities and everything possible should be done to bring the stimulating and critical influence of students within the walls of all the hospitals. There was in fact nothing to prevent the development of medical schools in association with municipal hospitals where facilities for teaching exist. Where they were developing on these lines, the confidence of the public in them was steadily increasing and they were being preferred by many to the voluntary hospitals. The public were beginning to feel that the hospitals belonged to them, that they could go there by right of citizenship, and not as a charity, and should anything go amiss that they had the right of protest through their elected representatives. In depressed areas local authorities had even been approached by voluntary hospitals with a request to be taken over.

The Local Government Act, 1929, came into being because intelligent administrators were impressed by the wastefulness of two systems of treatment—one for poor-law patients, and one for the public generally. If, Mr. Hastings concluded, the same Act was the means of freeing the public from the equally wasteful system of dual hospital administration, it would have proved itself of even greater value.

ROYAL INSTITUTE OF PUBLIC HEALTH

THE NORWICH CONGRESS

THIS year's congress was held at Norwich from May 15th to 20th, and was notable for the interest and originality of the communications made to the various sections, as well as for the pleasant excursions and "educational visits" which are among the valued amenities of these annual gatherings.

We noticed last week (p. 1074) the presidential address on conditions of employment. Among the discussions held by the section of state medicine and industrial hygiene was one on the

Milk Problem

opened by Dr. T. Ruddock-West, county medical officer of health for Norfolk, who said that the small amount of milk consumed per head in this country was attributable to (1) failure of the general public to appreciate the dietetic value of milk, and (2) the reluctance of the medical profession, while unanimous in opinion on the high nutritive value of milk, to advise its use, owing to the unsatisfactory state in which it reaches the consumer. Unless raw milk could be produced free from pathogenic organisms the only safeguard appeared to be universal pasteurisation. In either case it was necessary for the milk to be clean. Unfortunately the Milk and Dairies Acts and Orders had not been enforced rigidly. Legislation governing the production and sale of designated milk needed amendment. Dr. Ruddock-West said that milk naturally fell into one of two categories, clean milk and dirty milk, or in other words, tested and non-tested milk. In regard to tested milk the regulations in force in respect of Certified milk would meet the needs with certain modifications :—

(a) The herd should be tested against abortus infection every three months and reactors eliminated.

(b) Control should devolve upon the county councils and county borough councils in whose area the farms are situated.

(c) Farmers should be encouraged to produce tested milk and only a nominal fee, if any, charged for a licence.

Milk not conforming with the standards laid down should not be sold for human consumption unless it has been efficiently pasteurised, boiled, or dried. It was to be hoped that ultimately all milk would be of the tested class. Pasteurisation properly carried out would protect the consumer from the danger of infection with pathogenic organisms, though to adopt it universally without exploring other methods would be tantamount to acknowledging failure. Should other methods of dealing with the problem not prove efficacious there was always the last resort of pasteurisation. Dr. Ruddock-West was inclined to agree with the statement in the Ministry of Health Memorandum on Bovine Tuberculosis in Man, that the campaign in favour of clean raw milk must be regarded as of great potential value, and the unofficial grading of milk would constitute an important element in any comprehensive scheme for improvement in the milk-supply.

To a discussion by the section of women and children and the public health Mr. H. A. Brittain, orthopædic surgeon to Norfolk county council, contributed the opening address on the

Crippled Child

He spoke especially of the care of surgical tuberculosis from the hospital aspect, and devoted much attention to the difficult problem of diagnosis in very early cases. He was averse from postponing treatment until diagnosis was obvious to all, though this was to the benefit of statistics. At his hospital early doubtful cases were treated in various ways. In the first place the massage department, according to Platt, provided excellent diagnostic as well as therapeutic facilities; but the patient must be seen by the surgeon at least once a week. He had been confronted with a cold abscess on the tarsus after a month's massage. Absence of improvement on treatment should arouse suspicion, and any increase in the severity of the symptoms should clinch the diagnosis. Secondly, for the case which is almost certainly a strain, rest in bed at home was recommended for two to four weeks. If then symptoms had not cleared up the period of rest was repeated, and then if positive signs of a joint lesion still remained the case was treated as one of tuberculosis. In the third place, chiefly for the patient who might have an early pseudo-coxalgia, six weeks on a Thomas splint or in a plaster spica usually resulted in a complete loss of muscle-spasm and pain, but symptoms would recur in the tuberculous patient. These might seem rather elaborate precautions, but once a patient had been diagnosed as tuberculous he must be treated to the very end, remorselessly, in spite of the apparent immediate improvement. He had been taught the doctrine of immobilisation for at least one year after all pain and muscle-spasm were absent, and as his experience increased he found this period to be the minimum of safety. Mr. Brittain spoke also of the problems of the treatment of the established case, and of the residual or quiescent case in a general as opposed to a special hospital.

To this section also Miss M. F. Forrester-Brown, visiting surgeon to the Bath and Wessex orthopædic hospitals and county clinics, spoke on the

Organised Treatment of Motor Accidents

She pleaded for the earlier treatment of road injuries, which were so numerous and serious as to call for a special scheme of treatment. Information not at present available but essential to the solution of the problem included: (1) how many deaths were instantaneous, and how many occurred later and would have been preventable by more efficient treatment; (2) the degree and nature of the disabilities. Road accidents had much in common with war wounds. Organisation was needed for three stages: (1) the saving of life and limb, (2) repair of structure, (3) restoration of function, including working capacity. She pointed out the futility in rural districts preliminary of taking an accident case direct to the surgery of the local general practitioner, who more often than not would be out on his rounds. She reviewed the facilities available after the preliminary first-aid services rendered by the A.A., R.A.C., and, on certain occasions, by the Red Cross, comparing cottage hospitals to casualty clearing stations, the general hospitals to the base hospitals, and the orthopædic hospitals to the special hospitals, where the services of surgeons skilled in dealing with head and chest injuries would be available. A service possible in time of war should surely be possible in time of peace, and general constructive investigation was required.

Mr. Michael W. Bulman, consulting obstetrician and gynæcologist to the Norfolk county council, gave an address on

Abnormal Childbirth in the Rural Home

He discussed the causes of difficulty in rural midwifery—notably distances, home conditions, prejudice of patients against hospital confinement, and lack of trained nurses. With reference to prejudice, he said that many patients expected to be delivered in their own homes and saw no reason why the doctor should require special assistance. A doctor who frequently sent for a colleague to give an anæsthetic or who often advised his patients to go to hospital lost prestige. Prejudice was far more marked in the country than in towns and added to the difficulties already existing, if only by its effect on the morale of the doctor, who might feel dubious about advising treatment which he knew to be right, but which would not satisfy the patient.

Mr. Bulman quoted the following figures supplied to him by three local practitioners.

(*a*) In 32 years' practice, approximately 1400 cases.

Maternal mortality 2, of which 1 case was a placenta prævia "bled white" before sending for doctor; in the other the doctor was called in by a midwife to treat a ruptured uterus. A third case, not counted, died during labour of phthisis.

Puerperal septicæmia, 3.

Cases sent in labour to Norwich, 3.

Abnormalities dealt with included Cæsarean section, 4; decapitation, 1; craniotomy, 3; placenta prævia, 4; accidental hæmorrhage, 1; eclampsia, 4.

(*b*) In 10 years' practice, approximately 250 cases.

Maternal mortality, nil.

Cases sent in labour to Norwich, 1.

Abnormalities dealt with included puerperal septicæmia, 1; eclampsia, 1; craniotomy, 1.

(*c*) In 8 years' practice, approximately 600 cases.

Maternal mortality, nil.

Cases sent in labour to Norwich, 1.

This series include 2 cases of puerperal pyrexia and none of puerperal septicæmia.

Mr. Bulman said that (*a*) was a practitioner of the older generation and (*b*) and (*c*) had comparatively recently been translated from hospital conditions. If all practices could show similar results there would be no maternal mortality problem. The suggestions he offered after consultation with colleagues in practice in the country for the improvement of local conditions of childbirth were: (1) increase in the number of district nurses; (2) improved hospital accommodation where practitioners could, if they desire, treat their patients themselves under proper conditions. The provision of a county anæsthetist was advocated by many practitioners, since delay in obtaining a skilled anæsthetist when dealing with abnormal cases was often inevitable. It seemed to Mr. Bulman unlikely that the appointment of a special anæsthetist would overcome this difficulty. A few practitioners expressed satisfaction with present conditions and desired no change. He suspected that some of them feared, probably with justice, an increase in the already overwhelming amount of paper work and form-filling they were expected to do should any further facilities be officially provided. Any proposed maternity scheme should make provision for: (1) propaganda; (2) antenatal clinics; (3) sterile dressings; (4) district nurses; (5) consultants; and (6) coöperation between various workers. Propaganda should be directed not to emphasis on the dangers of maternity, but on the needs of the pregnant and parturient woman, and on the importance of proper supervision of pregnancy, and of proper surroundings for the confinement. Antenatal clinics should be staffed by general practitioners who must be fully conversant with modern antenatal requirements. Sterile dressings should be provided by public health authorities free of cost to necessitous persons. Though they would soon cease to be sterile, they would be far cleaner than the materials at present used as dressings by poor patients, and their use would have a good psychological effect on the patient, nurse, and doctor. All areas should have a district nurse, who should not be allowed to practise midwifery in competition with medical practitioners. The remuneration of both nurse and doctor required revision.

Among the communications to the section of veterinary medicine and agriculture was one on

A Consideration of the Treatment of Tetanus and Post-diphtheritic Paralysis

by Prof. RENÉ CRUCHET (Bordeaux). He described experiments on guinea-pigs which, he claimed, prove the phylactic action of inhalations of chloroform combined with injections of serum in tetanus and post-diphtheritic paralysis. He admitted that the results he had obtained are exactly opposed to those obtained by Debré, Ramon, and Uhry. These authors found that chloroform anæsthesia, combined with the injection of serum (either intravenously or intramuscularly, or subarachnoid injections), given in variable doses a few hours or a few weeks after the paralysing infection, had no preventive or curative action. Prof. Cruchet suggested that the negative results obtained by these workers might be due to the presence of formalin in their toxin. He was convinced from his own experiments, which he described, that in post-diphtheritic paralysis chloroform given before or after the injection of toxin protects the animal and prevents paralysis from occurring, and that chloroform has the same protective power as antidiphtheritic serum, since it is capable by itself of preventing paralysis.

Tuberculosis

Dr. S. VERE PEARSON, speaking of the arrangement of institutions in public tuberculosis schemes, quoted Dr. P. W. Edwards's figures of the after-results of artificial pneumothorax with and without phrenic evulsion. Taking the intermediate stage cases (T.B. + 2), of those who had pneumothorax with evulsion, 74 per cent. were alive after a period of three to nine years, of those who had pneumothorax alone 30 per cent. He would like to see specialist chest surgeons added as consultants and the institutions admitting cases of bronchiectasis and other non-tuberculous conditions. For this and other reasons large institutions—up to 300 beds—were preferable to smaller ones.

Dr. D. A. POWELL spoke of the need for careful diagnosis of tuberculosis in children in order to avoid unnecessary stigma. Treatment, he thought, should generally be in a separate block attached to an adult institution, except for the infrequent "phthisical" cases which local authorities should combine to segregate in a sanatorium. Other "thoracic" cases, with negative or no sputum, should be put in a sanatorium school. The "pre-tuberculous" or delicate child, predisposed by family history or environment, was best dealt with in open-air schools.

Dr. R. R. TRAIL considered the danger of isolation of the tuberculosis officer from the sanatorium with its modern methods, a danger made greater when an institution served a big area. Dispensary and sanatorium should, he thought, be regarded as one unit, so that the medical officer did not lose the opportunity of discussing with the patient his after-care. In the past the institution had been the ruling factor, but the lessons taught there were now being taken up everywhere by public health work. What we did not know in the treatment of tuberculosis was the morbidity of the disease. He would like to see the hospital with a dispensary attached and a week-end rest centre for ex-patients who came back for advice or a week-end's rest. He believed that way they would get a unified system.

Dr. F. W. Burton Fanning said that the proportion of early cases amongst admissions to sanatoriums varied from 25 to 40 per cent., and asked whether the doctor was to blame for late diagnosis, or the patient for not giving him a chance of making it. An impartial scrutiny of patients' histories made by Dr. W. E. Jolliffe and Dr. D. Wilson at Kelling, suggested delay or mistake on the doctor's part in 25 per cent., culpable delay on the patient's part in seeking advice in 20 per cent., and in 6 per cent. tubercle was discovered unexpectedly in the course of a routine examination for insurance or other purposes. Similar inquiries made in regard to 100 consecutive patients belonging to the more educated and wealthy classes suggested that the doctor had been unduly slow in making the diagnosis in 36 cases, and the patient had unduly delayed consulting him in 20. The balance in favour of the panel over the private doctor might be an example of the advantage of ready access to the tuberculosis officer with his full equipment for X ray and other investigations.

Dr. Evelyn M. Holmes referred to recent experimental work in Denmark. The Löwenstein-Jensen medium appeared to be extremely selective, enabling particles of sputum to be directly inoculated in the medium without preliminary washing. As a rule, the human type of bacillus gave a free growth after 17–21 days, the bovine type after 28–32 days; the growth obtained being quite different in appearance. Dr. Holmes gave the results of a series of tests, made over a period of months, on all the sputa received by a large laboratory which were T.B.-negative by ordinary staining methods. Over 50 per cent. gave a positive result by culture on this medium. The method had an obvious value in the examination of such things as pleural fluid, cerebro-spinal fluid, or pus obtained from joint abscesses.

MEDICINE AND THE LAW

Oysters and Typhoid Fever

After eating oysters at a St. Leonards hotel a visitor had an attack of typhoid fever which kept him away from his work for five months. He sued the hotel for damages for breach of warranty and negligence; the hotel denied liability and brought in the fishmonger who had supplied the oysters; he in turn brought in the company which sold him the oysters from its oyster-beds. There is nowadays a new procedure for these actions where third and fourth parties are involved. While the first party is attacking the second, the third and fourth are allowed to appear and cross-examine the witnesses but cannot themselves call evidence till the first issue is decided. There is a risk, of course, that the jury may take a view on the first issue which it would have rejected if it had heard the evidence subsequently called on later issues. At present the new third-party procedure is in the experimental stage; this case about the oysters is believed to have been the first of its kind to be dealt with by a jury under the new method.

As a matter of law the hotel proprietors had to admit that, if food was sold there which made the buyer ill, the seller was liable even though every care was taken to secure wholesomeness. There was no doubt the hotel management had been careful, and it was naturally argued that there was no conclusive proof that the typhoid fever was due to the oysters. The jury, however, was satisfied with the evidence given by Lord Horder and others on the plaintiff's behalf and awarded £725 damages. The case then entered the next stage, the hotel proprietors changing from defendants into plaintiffs and suing the fishmonger. He could not deny his legal responsibility in the face of the verdict already given; he therefore submitted to judgment for the sum of £725 in favour of the hotel and forthwith proceeded in turn to sue the company from which he obtained the oysters. He produced some new evidence. There had apparently been other cases of typhoid in Hastings at the material time. One of these patients had eaten oysters before his illness; did not this show that the oyster-beds had somehow become temporarily contaminated? The company which owned the oyster-beds had some fresh evidence too. Several persons at Hastings were called to say that they had had typhoid without oysters, several others to say that they had had oysters without typhoid—oysters, too, from the selfsame barrel as those which the original plaintiff had eaten at the hotel. Bacteriologists produced the records of the oyster-beds and gave them the highest character. Whereas the expert witnesses for the original plaintiff had inclined to suspect oysters as a not uncommon source of typhoid infection, the experts of the final defendants said that nowadays the suspicion was no longer justified. Dr. G. F. Buchan, medical officer of health for Willesden and author of books on typhoid fever, stated that, if there had been contamination of the beds as suggested, he would have expected a widespread outbreak of infectious disease wherever the oysters had been sent. He also thought the period of incubation of typhoid from shell-fish would normally be much shorter than in the original plaintiff's case. It might be only three days; the longer period was consistent with the disease having been contracted after leaving St. Leonards. The judge reminded the jury that no complaint had been made against the cleanliness of the fishmonger's premises or against his handling of the oysters. The jury came to the conclusion that the fishmonger had not satisfied them that he was supplied with contaminated oysters by the company. Thus, pending a possible appeal, the whole liability falls on him; he must pay the first plaintiff the damages of £725, and not only can he not pass on this burden but he must also pay the costs of the hotel proprietors and of the oyster company. Old-fashioned members of the legal profession who have not yet learnt to love the new procedure are asking whether the jury would have found in the first instance that the patient's typhoid was due to the hotel's oysters if it had heard the subsequently given evidence of those oysters' blameless upbringing.

Coroner and Doctor

At the resumed inquest at Leigh on the death of five miners in the Lancashire colliery explosion, a medical witness was questioned by the coroner (Colonel R. M. Barlow) about his action in having taken specimens of blood from four of the bodies without the coroner's permission. He explained that he understood that in any investigation after an explosion it was important for the blood of the men to be examined for carbon monoxide as early as possible; he had therefore taken samples at once. He had, he said, no object except the public good and had acted on request. The coroner, who eventually closed the incident by accepting the apologies of all concerned, stated that this was the third occasion within a year that there had been interference with a body which was in his custody. There was a question whether it did not amount to contempt of court. According to the authorities a coroner has undoubted powers of punishing contempt by fine or imprisonment, since his court has the dignity of what is called a court of record. There is less certainty as to these powers where the action of which he complains does not take place in the presence of the court. But it is in any case a common-law misdemeanour not only to prevent the holding of an inquest but also to obstruct the coroner in the course of his investigation. To tamper with a body, so that the coroner cannot be sure whether it is or is not in the same condition as when found, is clearly an interference which is technically an offence. It should be possible to arrange with the coroner's permission, or rather, indeed, under his actual direction, for prompt action in taking blood specimens in these cases. He will no doubt be fully aware of the evidential value of the earliest possible examination.

(FROM OUR OWN CORRESPONDENT)

NEW CHIEFS FOR THE PASTEUR INSTITUTE

SINCE the almost simultaneous death of Roux and Calmette a few months ago, the choice of their successors has engaged the attention of all concerned and of sundry others. Members of the executive committee have visited the various departments of the institute and have familiarised themselves with their activities. Although many names have been mentioned in connexion with the two vacancies, it is satisfactory that at the decisive meeting on the afternoon of May 17th the appointments were made by a unanimous vote. Louis Martin, the new director, was born in 1864, and is a brother of the present Minister of Finance. Martin's introduction to the Pasteur Institute in Paris dates back to 1892. Since then he has been continuously engaged on important research work, but being in charge of the hospital attached to the institute he has never lost touch with the clinical side of medicine. In 1894 the epoch-making communication on the serum treatment of diphtheria made at Budapest was signed by Louis Martin as well as by Roux. Among the notable contributions to medical science made by the new director are those concerned with experimental tuberculosis and the serum treatment of ictero-hæmorrhagic spirochætosis and trypanosomiasis.

While Louis Martin succeeds Roux, Gaston Ramon becomes sub-director, more or less in the place of Calmette. Ramon was born in 1886, and his name has for many years been associated with the anatoxin treatment of diphtheria. At Garches, only a few miles out of Paris, Ramon has been for several years in charge of that branch of the Pasteur Institute which is concerned with the preparation of diphtheria serum. When the possibility of his being appointed director instead of sub-director was being discussed, only one serious fault was found with him; he was too young. But as this defect will be corrected automatically, it is likely that eventually Ramon will guide the destinies of the Pasteur Institute with that combination of administrative ability and scientific acumen which have distinguished his sojourn at Garches. An innovation is the provision of the Pasteur Institute with a scientific council, whose members include Prof. Jules Bordet, of Belgium, and five other eminent pupils of Pasteur—Gabriel Bertrand, A. Borrel, Mesnil, Nicolle, and Yersin. The term of office of each member of this council is for one year only, but provision is made for re-election as well as for the appointment of new members as needs arise.

A NEW TREATMENT FOR SPRAINS

Four years ago Prof. Leriche, of Lyons, published a paper which set out some unorthodox views on the genesis and treatment of sprained joints which aroused some controversy. Two of his assistants, G. Arnulf and Ph. Frieh, have now [1] brought forward evidence in support of his claims, which are the more interesting in that they promise a shortened period of invalidism. According to Prof. Leriche a sprain is not due to rupture of a ligament. It is suggested that no one has ever seen such a rupture, but that it has been taken for granted; a hypothesis has become an affirmation, and eventually a dogma. In the two cases of sprains of the ankle in which he was able to look and see, Leriche found the external ligaments to be normal, not even infiltrated with blood. He holds that the lesion in a sprain involves the sensitive nerve-endings in a joint. A vasomotor reflex is set up and gives rise to œdema, a local rise of temperature, the familiar functional disturbances, and atrophy of the muscles involved. If, now, the injured parts are promptly infiltrated with novocain, even in the presence of œdema, hyperthermia, pain, and almost complete loss of movement, normal conditions are restored in a few moments; the patient no longer suffers pain, and is able to walk home quite happily. Often, after three or four hours the pain suddenly returns, lasts for an hour or two, and then disappears. On the following day a second injection, and in a few cases a third, may be required. The ailment, thus treated, is said to last a matter of only 48 hours. If Leriche's explanation is correct, the intraligamentary injection of novocain is successful because it breaks a vicious circle by blocking the centripetal impulses travelling to the brain from the injured nerve-endings in the joint. The technique is simple, and the injections can be given even by the practitioner whose knowledge of anatomy has become somewhat rusty. With the exception of the hip, most joints are easily accessible. A few c.cm. of a 0·5 to 1 per cent. solution of novocain are deposited in the periarticular structures, near a tender point if this can be found. With proper aseptic precautions there should be no risk of infection. A few moments after such an injection the patient is told to move his joint, and is generally astonished to find how suddenly and almost completely normal conditions have been restored. This treatment is said to be of value in the differential diagnosis of injuries to the joints, its failure indicating the existence of some gross lesion requiring a radiographic examination and the special treatment resulting from its findings.

IRELAND

(FROM OUR OWN CORRESPONDENT)

PROGRESS IN PUBLIC HEALTH

THE annual report of the Department of Local Government and Public Health for the year ended March 31st, 1933, has recently been issued. County medical officers of health have now been appointed in 18 counties, which include over three-quarters of the entire population. A number of assistant medical officers of health and public health nurses on a whole-time basis have also been appointed. School medical inspection has been begun in three additional counties. The number of children examined was 112,776, or about 30 per cent. of the children on the school-rolls. School meals schemes were in operation in 41 districts, and the number of children fed rose from 19,225 to 21,117 in the year. Every area except County Longford had adopted measures for the prevention and treatment of tuberculosis. The death-rate from tuberculosis in 1932 had fallen to 1·24 per 1000 of the population, the lowest on record. The death-rate of children under one year of age had increased, the rates being exceptionally high in urban areas. In Galway the rate was 136 per 1000 births, in Waterford 132, in Sligo 124, in Wexford 113, in Dublin 100. The rate for rural areas was 59 per 1000 births. There was an increased incidence and an increased mortality from diphtheria in both urban and rural areas. In Cork, where a scheme of immunisation has been working for some years, not a single immunised child died. Of the 17 deaths from diphtheria in Cork 10 were of children whose parents had refused to permit immunisation. The number of vaccinations performed showed a substantial decline: the vaccinations represented only 64·4 of the births registered.

---

[1] Presse Méd., April 14th, 1934, p. 597.

Although the report shows some progress in matters of public health the progress is slower than one has a right to expect. The appointment of a county medical officer of health for each county area was made compulsory by law in 1925, but in only two-thirds of the county areas has the law been obeyed. Moreover, it appears from a statement recently made in the Dáil by the Parliamentary Secretary to the Minister of Local Government and Public Health that there has been no addition to the number of county medical officers of health during the past 12 months. Medical inspection of school-children was established by law as long ago as 1919, and it is unsatisfactory that it is as yet only carried out for some 30 per cent. of children on the school-roll.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

AN OPHTHALMOLOGICAL LIBRARY

Dr. Emile de Grosz, well known abroad as president of the International Committee of the Campaign against Trachoma, is celebrating the completion of thirty years' tenure of the chair of ophthalmology in the University of Budapest. His clinic is famous, and in its development he has paid particular attention, among other things, to the development of a worthy library. The money grant made for this purpose by the Government was insufficient to keep abreast of scientific publications, and Grosz had to turn to some other source of support. Eventually this was found in the fees paid by the so-called "extra" patients attending the clinic, and the library proves the success of this plan. It is somewhat pathetic, however, to read the complaints made in his jubilee booklet against the high prices charged for books and periodicals, which make their purchase difficult. He mentions one book—"Kurzes Handbuch"—each volume of which costs 185 marks, while the whole work (seven volumes) cost 1780 pengos. In Hungary this is a very great sum; it is sufficient to buy quite a nice house in one of the suburbs of Budapest. The subscription price of German ophthalmological periodicals varies between 60 and 120 marks.

The clinic can boast having a complete library of antique books on the work of oculists. Most precious among them are Jacob Schalling's "Ophthalmia sive disquitio hermetico-gallenica de natura oculorum," which appeared in German and Latin in 1615 in Erfurt; Georg Bartisch's "Augendienst," published in Dresden in 1583, which, as the first ophthalmological manual, reached three editions; and a very valuable book, Vopiscus Fortunatus Plempius's "Ophthalmographia sive tractatio de oculo," the first edition of which appeared in 1632 at Amsterdam. A curious book is that written by Laurentius Heister, professor of surgery and anatomy at the University of Altdorf, "Apologia .... de cataracta glaucomate ... contra Wolhusii" (1717). This book was written by Heister in defence of his earlier published book against Woolhouse, a contemporary English physician.

DISPUTE BETWEEN THE GOVERNMENT AND BUDAPEST PHYSICIANS

Some months ago the Government informed the National Medical Association that they intended to establish a friendly society for public officials in such a way that medical attendance would be provided on the same basis as under national health insurance. The medical community forthwith revolted against this plan, which would curtail private practice and would mean advantage only to those physicians who got the posts. The association stated that the offer made by the ministry of finance could not be accepted and the latter then said that it was inclined to adopt the free-choice system, allowing public officials to choose their own doctors. The remuneration was fixed as follows: the Government was to pay for each unmarried public official with salary of less than 300 pengos (£17) monthly 12 pengos (14*s.*) a year, with other payments to correspond. Officials with salaries over 300 pengos monthly were to make their own arrangements with their doctors, the Government paying only the above fees. The National Friendly Society of Public Officials intends to establish also a dispensary employing specialists, who can be consulted by officials only upon the written opinion of the family physician. For each specialist consultation 30 fillers (about 4*d.*) will be paid by the society. The rumour of these rates of remuneration has caused consternation among doctors, who not only see in this offer the degradation of medical work, but are also clear that it will mean a general reduction of medical salaries which may be fatal to hundreds of practitioners. Hence the Medical Association, representing the whole medical profession of Hungary, has rejected the plan and resolved to boycott the society, if the Government will not raise the fees to a level worthy of the profession.

TRAINING FOR CRIPPLES.—At the annual meeting recently of the Royal National Orthopædic Hospital it was stated that last year out-patient attendances increased from 30,000 to 36,000. There is a prospect of the provision in the near future of a convalescent home of about 44 beds at Stanmore. The annual report emphasised the need of the training school for cripples which the committee hope soon to establish also at Stanmore.—The subject of training was raised also at the annual meeting last week of the Royal Cripples' Hospital, Birmingham. It was then reported that an endeavour was being made to ascertain the number of cripples requiring training, and the attitude of the responsible authorities towards grants for the purpose. The hospital's income of £56,775 left a deficit of £253. The Contributory Association paid £12,554, and a further sum exceeding £14,000 was received in respect of the treatment of contributors and their dependants, which represented 85 per cent. of the cost. The possibility of erecting wards for paying patients is under consideration.

OBITUARY

DAVID OGILVY, M.D., B.Ch. Dub.

MEDICAL SUPERINTENDENT, MENTAL HOSPITAL, L.C.C., EPSOM

As has already been announced, the death occurred on May 13th of Dr. David Ogilvy, superintendent of the London County Council Mental Hospital at Long Grove, Epsom. He had been in bad health for some time, and the death of an efficient and capable officer at the age of 61 is deeply regretted. He was the youngest son of the late Alexander Ogilvy of Dublin, and received his medical education at Trinity College, Dublin, where he graduated as M.D. in 1889, gaining the first place in surgery in the final examination. He also represented his university at Rugby football.

DAVID OGILVY

Ogilvy's whole professional career was spent in the study and treatment of mental disease. In the year of his graduation, after a short period as resident at the Criminal Asylum, Dundrum, he came to England and was appointed assistant medical officer at the West Riding Asylum, Wakefield, where he had the advantage of serving under the late Bevan Lewis, whose pioneer work in psychiatry was remarkable. He then joined the L.C.C. service and was appointed an assistant medical officer in the Banstead Asylum under the late Claye Shaw. In 1902 the Horton Asylum was opened, and Ogilvy was appointed second assistant, being soon promoted to be senior medical officer. Here he remained working under the late Colonel J. R. Lord until he was selected in 1912 to succeed Sir Hubert Bond at the Epsom (Long Grove) Mental Hospital, Bond having become a Commissioner in Lunacy.

We owe to a colleague in the L.C.C. mental service the following appreciation of David Ogilvy. "On appointment to Long Grove, Ogilvy realised fully the distinguished heritage committed to his care, and unsparingly devoted himself to the great work he found there. He took a special interest in the development of occupational therapy on progressive lines, and it was due to his persistent advocacy that a male occupations therapist was appointed for the male division, with such progressively satisfactory results in this form of treatment. He was a man of strong personality, courageous, straightforward, and tenacious of purpose, which was always devoted to the welfare of his hospital. His transparent honesty and sense of justice in connexion with what he conceived as right, was rewarded by the respect and affection of his staff, and from his patients his humanity, kindliness, and devotion to duty secured a ready response. Amongst his medical colleagues he held a special place, and his fearless manner, outspoken speech, and readiness to fight for a good cause endeared him to all who knew him well. One might differ from Ogilvy, but one could not help liking him, and to his more intimate friends he was always affectionately known as 'O.' He was a member of the Royal Medico-Psychological Association, and he took a deep interest in the Mental After-Care Association, on the council of which he served.

"Whether or not Ogilvy was temperamentally an optimist, his attitude towards life was certainly one of determined optimism, not lost in his last illness. He was approaching the natural termination of his service, and a well-earned retirement, into which he would have taken the good wishes of his fellow-workers, had destiny so decreed. He leaves a widow and three children, to whom all who knew him will tender their heartfelt sympathy."

No more conventional portrait of Dr. Ogilvy was available for publication.

RICHARD H. C. GOMPERTZ, M.B., B.S., B.Sc. Lond.

THE death of Dr. Richard Henry Cyril Gompertz, of Barnstaple, has removed from North Devon a practitioner whose public and voluntary work, discharged in addition to the duties of a large practice, benefited the neighbourhood in a noticeable way. Born in 1877, at Madras, the son of an officer in the Indian Army, Gompertz was educated at Bedford Grammar School and King's College, London, and received his medical education at King's College Hospital. Here he was a distinguished student, being both junior and senior Cloth Workers' scholar and Sambrooke scholar. He graduated M.B., B.S. Lond., in 1907, with honours in medicine and surgery, obtaining a gold medal, and later was appointed surgical registrar to the hospital and demonstrator in physiology in the school. At the outbreak of war he served with a temporary commission in the R.A.M.C., and was mentioned in despatches. At the close of hostilities he was for a time medical officer to Berkhamsted School, while at the same time he developed his knowledge of radiology and took part in public duties by coöperation with the St. John Ambulance Association. In 1923 he joined a firm of practitioners in Barnstaple, and in addition to his routine work, was appointed to the charge of the X ray department of the North Devon Infirmary. He continued his close interest in ambulance work, was medical officer to the local Voluntary Aid Detachment, lectured in connexion with the St. John Ambulance Association, and was medical referee under the Workmen's Compensation Act. He was a widely read man, especially in psychology and the later theories of evolution, while he was also a considerable artist and botanist and a prominent lawn tennis player. An all-round and accomplished man, his death at the age of 57 is a loss not only to his circle but to the medical profession.

Dr. Gompertz married in 1920 Marjorie Whitfield, and leaves a widow and two children.

WILLIAM PRINGLE MORGAN, M.B. Dub., D.P.H.

Dr. Morgan, who died at Seaford, Sussex, on March 20th, in his 73rd year, was a practitioner who left a deep impression on those he had served and in whose activities he had shared. He was born at Rostrevor, Northern Ireland, the son of the Rev. Thomas Morgan, educated at Dundalk Grammar School, and Trinity College, Dublin, where he graduated in 1885. In the following year he settled at Seaford, and shortly after took his D.P.H. In 1889 he married Miss Ethel Eastwood of that town—or village as it was then—and for 45 years he watched its growth and consolidation. In due time he became chairman of the urban district council, being elected in two succeeding years. In masonic circles he was well known, being master of the Seaford lodge and in 1911 provincial junior grand deacon. Although over age he served in the war at Malta and Salonica. He was a member of the Sussex Archæological Society and of the Society of Sussex Downsmen; and was chairman of the local branch of the League of Nations Union. He took an active part in the work of the B.M.A., and in 1925 was president of the Sussex branch. A colleague writes :—

" Morgan believed intensely in Voltaire's principle 'il faut cultiver notre jardin'; but for him, highly endowed though he was, it was not just a matter of watering, but of sowing and then watering. He did not expect himself, or anyone, just to sit with their inherent gifts. To the end he retained a fascinating and informing interest in his work, in his pursuits, in literature, in music. His leisure was always utilised; he never lounged in thought or action. He hated slovenliness of speech or talk, and his own finely spoken words and ringing enthusiasm will go on echoing through many people's lives. Such a man cannot be easily forgotten."

Mrs. Morgan survives him, together with two daughters and two sons, of whom the elder is ophthalmic surgeon to Guy's Hospital.

WILLIAM BROGDON PATERSON, M.B. Edin.

THE death of Dr. W. B. Paterson, at his home at Aigburth, on May 11th, removes a practitioner who was widely known and respected in Liverpool. He was born in 1865, his father being minister of Tranent, East Lothian. He was schooled in medicine at Edinburgh, where he qualified M.B., C.M. in 1887, afterwards becoming resident physician at the Cowgate Dispensary. He went to Liverpool as house surgeon to the Royal Southern Hospital, was for some time medical officer to the Liverpool Medical Mission, and then became a partner of the late Dr. John Grimes, of Grassendale, with whom he remained until 1903. Until a few years ago he was associated in partnership with Dr. H. R. Hurter, of Cressington. His colleagues honoured him at various times by electing him first librarian and later vice-president of the Liverpool Medical Institution.

Dr. Robert Coope writes : " Paterson's stocky figure, with bright and kindly eyes shining from behind rather shaggy eyebrows, became well known to the men and women of all walks of life who made up the field of his large and widely extended family practice. His skill as a practitioner kept pace with the rapid advances of medicine, and to his professional duties he brought a discipline and integrity of purpose which left him with neither time nor inclination to waste words or energy on small talk or trivialities. At times life had hit him hard, but he emerged out of disappointment and sorrow to a fine sensitivity and sympathy, which was all the stronger for his reticence.

" His love of the beautiful in life brought him delight in art, in the engaging loveliness of children, and most of all in the contacts of his daily work. He possessed that austere sense of fitness and restraint which is associated with the classical Greek spirit, but with it were fused a serene kindness and an unusual power of feeling. A man's relations with children are a revealing touchstone of his quality; I had the intimate privilege of seeing how, busy as he was, he treated children with winning dignity and seriousness, so that they loved him and regretted that he could not stay longer on his visits. I learned, too, his power not only of saying the right thing but of giving that rare sympathy which has an astringent and strengthening quality in it."

FRANCIS SEYMOUR KIDD

A COLLEAGUE of Mr. Frank Kidd writes : " May I add a few words to the obituary notice published in THE LANCET on May 19th? In 1913 Frank Kidd started the genito-urinary department at the London Hospital, which from small beginnings has become one of the largest special departments, and soon established his reputation as one of the leading urologists in England; his enthusiasm for this branch of surgery was originally stimulated by his old chief, Mr. Hurry Fenwick. As Kidd's reputation increased so did his private practice, and by the end of 1920 he found that his health was unable to stand the strain of both his large practice and his arduous work at the London; so on medical advice, and greatly to his own sorrow, he resigned from the London and did no more hospital work except in the capacity of consulting surgeon to St. Paul's Hospital. But although he had left the hospital he loved, he never allowed his enthusiasm for urology to wane, and in 1920 was a member of the organising committee that founded the urological section of the Royal Society of Medicine. He acted as honorary secretary of the section from 1921 to 1923, and in 1927 was president. He read many papers at the section and contributed frequently from his extensive experience to the discussions. In 1928, in collaboration with Mr. Winsbury-White, he worked hard in starting the *British Journal of Urology*. The first number was published in March, 1929, and Kidd's enthusiasm enabled him to acquire an editorial committee drawn from the best-known British urologists, while he himself became editor, with the assistance of Winsbury-White, who later carried on alone when Kidd's health broke down. From the start the publication was a success, and it is a general hope that it will remain as a lasting memorial to its founder. Through text-books and papers on urological subjects, Kidd's name was well known throughout Europe and America; he was twice invited to address the American urologists in conclave, going to the United States for the purpose, while he acted as secretary to the British section of the International Association of Urology.

" As well as having such an extensive knowledge of his subject, Kidd was a very skilful operator, and nothing was too much trouble where his patients were concerned. Into those of us who had the pleasure and privilege of working with him, he was able to instil his own enthusiasm; he was our loyal colleague and a generous friend to those who worked with him. Unfortunately his physique was not in keeping with his restless energy; he found it very difficult to relax, so that the strain told more and more on his health, and in November, 1932, following a motor accident, his health broke down and he had to retire from practice."

ENLARGEMENT OF SALISBURY INFIRMARY.—It has been decided to enlarge this hospital from 171 to 226 beds at a cost of £85,000, to be provided by public subscription. There will, in addition, be a paying ward of 15 beds. The enlargement is intended mainly to provide for specialist needs. A proposal to build an entirely new hospital at a cost of £900 per bed was rejected. Last year 2429 in-patients were admitted, who stayed on an average 19·7 days.

CORRESPONDENCE

SANITY IN A MENTAL WARD

To the Editor of THE LANCET

SIR,—The letter of Dr. Edwin Goodall in your issue of May 19th—so convincingly sound—will I am sure be welcome to all those practising and interested in psychiatric medicine. As he truly states : " This provision, regarded as elementary, and long since made on the continent, has been urged for this country to my personal knowledge for 40 years—and probably longer." But the opening of Shenley Mental Hospital by the King and Queen on May 31st may create a revolution as unique as any " opening " in the hospital world of medicine. Is it not another royal example of profound interest in British medicine ? If it should lead constructively to a further type of general hospital similar to that at the Johns Hopkins Hospital, Baltimore, we shall be advancing in preventive medicine. With mental cripples on one side and physical cripples on the other, what can be more ideal ?

I am, Sir, yours faithfully,

Ryhope, May 21st. JOHN FREDERICK BRISCOE.

PANCREATIC INSUFFICIENCY IN GRAVES'S DISEASE

To the Editor of THE LANCET

SIR,—Encouraged by the favourable criticism of some of my colleagues I am bringing to your notice a method of treating exophthalmic goitre by the oral administration of an extract of the pancreas. Since 1931 I have treated with uniform success a series of ten patients of ages ranging from 23 to 57. The conditions of my work do not allow me to present records with detailed metabolic investigations, but I have good reason to be satisfied of the value of the remedy, and would be therefore glad of the coöperation of those with facilities for examination and continuous treatment on a larger scale.

Authorities on Graves's disease may admit an associated lesion of the thymus gland, suprarenal cortex, liver or other lymphoid tissue ; but the pancreas is not singled out as showing pathological changes. Yet outside the usual Graves's syndrome we get such symptoms as diarrhœa, glycosuria, and increased appetite, indicating that the pancreas is possibly involved. It seems to be firmly established that there is deficiency of iodine in the thyroid gland in Graves's disease, and Marine holds that the gland enlargement represents a compensatory hyperplasia. The deficiency may, he suggests, arise either because there is a diminished amount of iodine in the diet, or because the body for some reason requires an increased supply, or because there is something which blocks tissue oxidation. May not this block be in the pancreas, impairment of whose function leads to imperfect absorption of fats and proteins ? In practice I have found that pancreatic extract will sometimes control diarrhœa of long standing, and in a very severe case of Graves's disease of 18 years' duration I gave the extract to combat typical pancreatic stools. The diarrhœa cleared up in a day or two and to my astonishment the large goitre disappeared within a fortnight, and the patient's general condition improved out of all knowledge. This encouraged me to try the extract in the case of a woman who had been treated for some time with Lugol's iodine. She had all the symptoms of Graves's disease, well marked, with occasional loose stools ; but after six months' treatment there was no longer any evidence of thyrotoxicosis. I shall not here give details of the others treated, but it is interesting to note that out of ten the only case which has not completely reacted to the treatment is one in which pancreatic disease is well established ; and even here the cure is almost complete.

As a rule it takes from six months to a year for the usual symptoms to disappear, but the patients carry on meantime with their ordinary duties. The blood pressure and basal metabolic rate show improvement fairly quickly and the patients soon notice an amelioration of their symptoms. In some cases I have given the extract alone ; in others I have combined Lugol's iodine with it. The preparation used is Oppenheimer's palatinoids Pancreatin grs. 5, given thrice daily immediately before meals.

Prof. C. Harington in his book the "Thyroid Gland," in discussing the possibility of lesions of the pituitary gland and suprarenal cortex in thyrotoxicosis, sums up thus :—

> "Neither of these hypotheses can be advanced as a serious theory of the ætiology of Graves's disease. They are discussed here because it seems to the writer that it is almost certainly on some such lines that the explanation of the problem of Graves's disease will eventually come. The only practical means at present of handling the condition consists of a palliative surgical measure devoid of any rational basis."

Does not insufficiency of the pancreas fill the gap to which Prof. Harington refers ?

I am, Sir, yours faithfully,

Liverpool, May 16th. C. BAIRD MACDONALD.

UNFORTUNATE PUBLICITY

To the Editor of THE LANCET

SIR,—I write to disclaim all responsibility for the publicity given to my name in a professional capacity in the lay press. Recently my name appeared in a newspaper article in which the following statement was made : " At first-hand from the doctors and their patients themselves, I have learned how all these astonishing operations are being performed." I have never discussed my professional work with representatives of the lay press, and have never conveyed information to them directly nor by any indirect channels. Requests for interviews have been consistently refused.

I am, Sir, yours faithfully,

J. W. TUDOR THOMAS.

Clifton Lodge, Cardiff, May 20th.

MEASLES SERUM IN A CASE OF ULCERATIVE COLITIS

To the Editor of THE LANCET

SIR,—The following case is, I think, of sufficient interest and importance to justify its being reported. An otherwise healthy young girl, aged 21, was recently under my care suffering from her third attack (within three years) of ulcerative colitis, which had been going on uninterruptedly for just over three months. Her previous attacks were less severe and lasted approximately one month and two months respectively.

On expectant treatment she was doing badly, passing blood and mucus about six times a day, and an ileostomy was contemplated. As her brother, who had been in contact with her, developed a typical attack of measles, it was deemed advisable to immunise her, as she had not previously had this disease. She was accordingly given 12 c.cm. of convalescent measles serum intramuscularly into the thigh. Within 48 hours there was marked improvement in her condition, both local and general, and within a week the blood and mucus, which had by this time increased sufficiently to cause some concern, entirely disappeared and her motions became perfectly normal.

I have heard of other cases of ulcerative colitis that have cleared up equally dramatically after a blood transfusion. I would, therefore, ask those who have an opportunity of seeing and treating a number of cases of this very distressing, though fortunately rare, disease, to try this method of treatment and publish their results. My feeling is that ordinary human serum would act as well as convalescent serum.

I am, Sir, yours faithfully,

L. CARLYLE LYON, M.B.

Creffield-road, Ealing, May 14th.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Whitsuntide Adjournment

ON May 17th the House of Lords adjourned for the Whitsuntide recess until May 30th. The Royal Assent was given to a number of Acts, including the Births, Deaths and Marriages (Scotland) (Amendment) Act, and the Water Supplies (Exceptional Shortage Orders) Act.

In the House of Commons on May 18th the Birmingham United Hospital Bill was read the third time. The House adjourned for the Whitsuntide recess until May 29th.

Psycho-physical Tests for Drivers

When the Road Traffic Bill was considered by a Standing Committee of the House of Commons on May 17th, on Clause 5 (Tests of competence to drive of new applicants for licenses and of offenders ordered to be tested), Sir ERNEST GRAHAM-LITTLE moved an amendment providing that applicants should be required to pass a prescribed psycho-physical examination for fitness and subsequently the prescribed test of competence to drive. Tests had been worked out by the Institute of Industrial Psychology in many other walks of life, and the experience which had been gained by expert observers in studying the causes of accidents in factories was a very material argument for the consideration at any rate of the subject in the case of motor accidents.

There were 106,000 factory accidents in one year, of which 66,000 were considered by experts observing them to be due not to carelessness or the act of God, or anything else fanciful, but to real conditions in the personnel of the factory. In the case of the breakage of crockery in restaurants when the employer tried to meet it by punishment for carelessness, fines, and so on, the progress made was negligible, but when experts studied the matter a very different state of affairs was revealed. When psycho-physical tests were instituted in these cases a very remarkable result followed, and breakages were greatly reduced. They were very commonsense tests. Fatigue, rush hours, bad ventilation, poor lighting, and emotional states all entered into the production of accidents. The practical utility of the tests was immediately demonstrated, and it was instructive to note that in a report by the Chief Inspector of Factories in 1932 he stated that it was of very little utility to go on trying to meet factory accidents by improvements in machinery. They had practically exhausted the usefulness of that line of research. When they began to treat the human factor progress had been enormously greater and it was the human factor that he proposed they should consider in this amendment.

HUMAN FACTOR IN ACCIDENTS

What was the estimated ratio of the human factor in the production of accidents upon the roads? That was very difficult to estimate, because unfortunately the evidence had been derived from uninstructed sources. Policemen and coroners had been the principal witnesses, and chief reliance had been placed on their statements as to the causation of accidents. But where expert investigation had been made it had been conclusively shown that it was the same cause in road accidents as had operated in factory accidents. The human factor was by far the more important of the two producing that result. He (Sir E. Graham-Little) had been in close touch with the Institute throughout. The director had himself given here a proposed category of tests, and it was that combination which he suggested might be considered as being a practical application of this amendment.

The tests were divided into three classes. The first was the investigation of factors determining the capacity of response to an emergency. Under that heading three inquiries were made. The first quality that was tested in that way was the simple reaction time. The test was made by the person tested pressing upon certain levers when certain lights came into view, and the test was the *simple reaction time undisturbed by any other factors.* A very remarkable fact that emerged was that response was very different in different persons. It might vary from half a second to a second and a half—a difference of 150 per cent. The next test was the reaction time confronted with distraction, and a very ingenious method had been devised. A film was exhibited and the observer was required to press the levers while looking at the film. In the case of an interesting film the reaction time was very materially increased. The third test was that of vigilance. That was made by putting on a film and cross-examining the tested person. He must remember something about the film as well as press the levers when the lights went up. That was again a more prolonged reaction time. Under the second heading were tests for ability to make rapid and accurate judgment of the size of objects, the space between objects, distances and speeds—a very simple apparatus and an extraordinarily efficient one. The third category was tests of vision both with regard to acuteness of vision and the condition of the eye muscles—a highly important factor in estimating distances. He did not suggest that they should include a medical test. It would be much too expensive, and experience had shown that gross disabilities, as, for example, hearing, came out in the application of the physical tests. They could tell at once if a man could not hear when one was talking, and attention might be directed in that way to the importance of a professional examination of the candidate.

THEORY AND PRACTICE

The scientific accuracy of the investigations might be estimated in this way. The correlation between the scores made at the Institute and the accident records of persons tested in a large number of cases had been singularly close. There was no doubt that from the scientific point of view the tests were absolutely to be relied upon. He would emphasise the importance of the reaction time by one statement.

It had been said that one could stop in the distance of one's car own, which was demonstrably impossible. There was a formula for estimating braking distance which had been mathematically worked out and was accepted by motorists' associations, and to the braking distance they must always add a figure which varied with the reaction time, and on the average, as a rough estimate, it might be taken that if one wanted to get the stopping distance they must add to the braking distance a figure in relation to the velocity of the car in miles. If one was going 30 miles an hour one must add a distance of 30 feet. That was a very material accentuation of the problem of stopping, and he thought it was often entirely ignored by motorists.

APPLICATION OF THE TESTS

The actual application of these tests had been made on quite a large scale, not unfortunately in this country, although the greater part of the work had been done in this country. It had been applied far more extensively in other countries, notably in France, the United States, and Germany. Some figures had been given of experience in Paris.

In one comparison of a certain number of private cars, lorries, and practically all vehicles not omnibuses or trams the accidents in ten years were investigated, and it was found that the accident rate increased in that period by

PANEL AND CONTRACT PRACTICE

Vexed Points in Certification

THE note under this heading in our issue of April 28th (p. 919) has led to rejoinder based, we think, partly on misunderstanding. For instance, Dr. X. writes: "Your notes on giving certificates to pregnant women show that the approved societies have again attempted to increase the clerical work of panel practitioners, but with all their ingenuity the societies have not evolved a formula which will enable me to state the reason why I consider a case, such as a pregnant land worker, unfit for work. English medicine is still an affair between doctor and patient which is conducted viva voce. Few patients ever read their medical cards; fewer still their certificates. If one simply wrote instructions on the certificate and then asked the patient why they were not followed, the answer would be that the doctor did not tell the patient. To write these instructions is simply to inform the society what they are, nothing more." In making his point Dr. X. is not quite fair to the approved societies, for the suggested rules were arrived at by a meeting between representatives of approved societies and members of the Insurance Acts Committee, and were only simply a consensus of opinion. They have not yet even been considered by the Ministry of Health. Nevertheless one can hardly imagine a doctor writing instructions on a certificate to come again on a particular day without at the same time instructing the patient by word of mouth to do so. And it may well be asked: How can a society find out how verbal instructions to attend are obeyed unless they are confirmed in writing on the certificate?

Commenting on the statement of approved society representatives that it is rare to find filled in on the certificate the date on which the patient is to see his doctor again, Dr. X. remarks: "It is simply untrue to say that 'patients are apt to attend weekly'; they attend when they are told to do so, and the most practical method of securing this is to limit the amount of medicine they receive to what they can consume in the interim. If they then fail to attend, a question as to how they expect to get well without medicine will do more to secure attendance than any effort the society can make. Most patients are grateful to find they are not obliged to make attendances specially for certificates. The system of attendance on the same day of the week finds favour with some agents who like paying definite weekly sums instead of working out the sums in sixths and paying the number of sixths to which a man is entitled. The much abused English monetary system is peculiarly adaptable to the division of small sums into sixths. It would be well for societies to scrutinise their agents' reports to discover which are paying the bulk of the claims in weekly sums and which in four-sixths, seven-sixths, and so on. Such a list would inform them which agents are doing their work and which, by avoiding a little extra trouble, are increasing work for doctors and attendances for patients." But Dr. X. seems to overlook that on the question of payment for parts of a week in sixths agents are bound by the rules of their societies: Some allow payment up to the date of certificate, others only to the weekly pay-day; others, again, pay up to the date of the weekly pay-day provided a certificate has been given during that week—thus often paying a day or so beyond the date of the certificate.

Dr. Y. raises the question of breach of confidence on the part of the doctor who certifies pregnancy. "Many women," he writes, "are content to allow their agents to remain in ignorance of what their doctors know. It is perhaps too much to contend that to inform the official of a London society who does not know the woman that she is seven months pregnant is a breach of professional confidence, but the certificate may be seen by the local agent. If she runs me in for allowing her agent to know when to expect the confinement, will the fact that I cannot obtain sick pay for her without running the risk of doing this be an adequate defence?" The answer, of course, is that there is no breach of confidence in writing anything upon a certificate, marked confidential, given to the patient by the doctor. It is the patient who hands it or sends it to the head office or to the local agent; it is therefore the patient, not the doctor, who is responsible for the publicity of its contents. There is, however, a provision in the certification rules whereby a doctor may give an indefinite diagnosis on a certificate for the patient to hand to the society; but if he does so he must at the same time inform the regional medical officer of the precise diagnosis, and let the society know that the certificate is not as precise as it might have been. The form provided for this purpose is Med. 40 D. It might be used where pregnancy occurred in a single girl or in the case of venereal disease where loss of employment or other damage would result if the precise diagnosis were to become known locally. It could hardly be used to hide the probable date of confinement in a known case of pregnancy.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 12TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 3 (last week 2); scarlet fever, 2658; diphtheria, 1163; enteric fever, 25; acute pneumonia (primary or influenzal), 1060; puerperal fever, 57; puerperal pyrexia, 110; cerebro-spinal fever, 22; acute poliomyelitis, 5; acute polio-encephalitis, 2; encephalitis lethargica, 7; dysentery, 4; ophthalmia neonatorum, 90. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 21st–22nd was as follows: Small-pox, 14 under treatment, 0 under observation (last week 9 and 3 respectively); scarlet fever, 1594; diphtheria, 1669; measles, 2493 (last week 2740); whooping cough, 304; puerperal fever, 32 mothers (plus 11 babies); encephalitis lethargica, 259; poliomyelitis, 3; "other diseases," 125. At St. Margaret's Hospital there were 12 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 78 (30) from measles, 10 (2) from scarlet fever, 35 (4) from whooping-cough, 42 (12) from diphtheria, 45 (16) from diarrhœa and enteritis under two years, and 48 (5) from influenza. The figures in parentheses are those for London itself.

Deaths from measles and whooping-cough are steadily on the decline, but 11 fatal cases of measles were reported from Liverpool, 7 from Newcastle-on-Tyne, and 4 from Barnsley, while Liverpool also reported 8 fatal cases of whooping-cough, Birmingham 5. Diphtheria proved fatal in 3 cases at Ilford and 3 at Birmingham.

The number of stillbirths notified during the week was 208 (corresponding to a rate of 44 per 1000 total births), including 47 in London.

MEDICAL NEWS

University of Oxford

Dr. C. F. T. East and Dr. C. P. Symonds have been nominated by the general-medical electorate to the board of the faculty of medicine.

Dr. John Carew Eccles, Staines medical fellow of Exeter College, has been elected to an official fellowship and tutorship of Magdalen College.

University of London

At a meeting of the senate on May 16th the title of university reader in bacteriology was conferred on Dr. L. P. Garrod, bacteriologist and lecturer in bacteriology to St. Bartholomew's Hospital medical college. Dr. G. R. Cameron, since 1933 pathologist to the Queen Mary's Hospital, Stratford, was appointed university reader in morbid anatomy at University College Hospital medical school.

The degree of D.Sc. in physiology was conferred on Dame Louise McIlroy, university professor of obstetrics and gynæcology at the London School of Medicine for Women.

Royal College of Physicians of Edinburgh

The Kirk Duncanson fellowship for medical research will shortly be awarded. Particulars will be found in our advertisement columns.

Royal College of Surgeons of Edinburgh

At a meeting of the College held on May 16th, with Dr. A. H. H. Sinclair, the president, in the chair, the following candidates having passed the requisite examinations were admitted Fellows :—

Paul Joseph Fogarty, M.B. N.Z. ; Samuel John Campbell, M.B. Belf. ; Samuel Davidson, M.B. Edin. ; David John Davies, M.B. Lond. ; Morgan David Arwyn Evans, M.D. Wales ; John Malcolm Fosbrooke, M.B. Edin. ; Kennedy Hunter, M.B. Belf. ; Morris Louis Kaufman, M.B. Liverp. ; David Henry Klugman, M.R.C.S. Eng. ; James Lawrie, M.B. Edin.; Charles Roy Macdonald, M.B. Edin. ; Donald Couper Mackenzie, M.B. Edin. ; John Campbell Mackenzie, M.B. N.Z. ; Alfred Ian Lennox Maitland, M.B. Glasg. ; Ian Morison Orr, M.B.Glasg.; Llewelyn Courtenay Palmer-Jones, M.B. Edin. ; Jack Polonsky, M.B. Liverp. ; James Henry Gordon Robertson, M.B. Edin. ; Brian Powell Robinson, M.R.C.S. Eng. ; and Dorothy May Satur, M.B. Madras.

The following candidates received the higher dental diploma :—

Geoffrey Brocas Hunter, Reginald Edward Clarke, John Walter Shaw, and Horace Hayman Boyle.

University of Liverpool

The following awards have recently been made in the faculty of medicine :—

Gold medal for medicine, J. K. B. Waddington, proxime accessit : Margaret F. Procter ; clinical school exhibition (clinical medicine), A. J. McCall ; A. C. Rich prize (clinical medicine), E. W. Jones ; gold medal for surgery, A. C. Brewer ; Derby exhibition (clinical surgery), J. G. Sheldon ; gold medal for obstetrics and gynæcology, A. J. McCall, proxime accessit : Margaret F. Procter ; and Robert Gee prize (diseases of children), V. K. Drennan.

University of Dublin

The fourth series of the John Mallet Purser lectures will be delivered by Prof. C. U. Ariens Kappers, director of the Institute for Brain Research of Amsterdam, in the department of physiology of the medical school. On Tuesday, June 12th, he will speak on the differences in the effects of various sensations on the structure of the nervous system ; and on Thursday, June 14th, on the so-called Semitic and Aryan peoples in the Near East. The lectures are open to the public and will be given at 5 P.M. each day.

Research Defence Society

The annual general meeting of this society will be held at the London School of Hygiene and Tropical Medicine, Keppel-street, London, W.C., on Tuesday, June 5th, at 3 P.M., when the eighth Stephen Paget memorial lecture will be delivered by Mr. Joseph Barcroft, F.R.S., professor of physiology in the University of Cambridge. His subject will be experiments on man. Lord Lamington, the president, will take the chair and he will be supported by Sir Arthur Stanley and Prof. A. V. Hill, respectively chairman and vice-chairman of committee.

Prof. F. E. Tylecote, F.R.C.P., has been placed on the commission of the peace for the city of Manchester.

South-West London Medical Society

The Bolingbroke lecture will be delivered to this society at the Bolingbroke Hospital, Bolingbroke-grove, Wandsworth Common, at 9 P.M., on Wednesday, June 6th, by Mr. Comyns Berkeley, who will speak on Some Things I have Learnt. The arrangements previously announced have been cancelled.

National Smoke Abatement Society

This society, whose president is Dr. H. A. Des Vœux, is arranging a symposium on smokeless open-grate fuels. The papers will be delivered at an open meeting to be held at 71, Eccleston-square, London, S.W. 1, on Friday, June 8th, at 11 A.M., and there will be a discussion. The address of the general secretary is 23, King-street, Manchester 2. The annual conference of the society will be held at Glasgow from Sept. 27th to 29th.

Glasgow Post-Graduate Medical Association

This association has arranged for a general medical and surgical course to be held from August 20th to Sept. 14th. The mornings will be occupied with general medicine and surgical diagnosis and minor surgery at the Royal Infirmary and the Victoria Infirmary, while the afternoons will be spent in studying special subjects. Clinical assistantships are also available in some of the institutions taking part in the work of the association. Further information may be had from the secretary of the association at the University, Glasgow.

Committee against Malnutrition

Under the auspices of this committee, whose aims were described in our issue of April 21st (p. 865), a public meeting will be held on Wednesday, June 13th, at 8 P.M., at 34, Red Lion-square, Southampton-row, London, W.C., to discuss "the steps to be taken in combating the widespread undernourishment of men, women, and children." Among the speakers will be Dr. Stella Churchill, Prof. J. B. S. Haldane, F.R.S., Dr. R. D. Lawrence, and Dr. R. A. Lyster. Tickets at 1s. each may be had from the hon. secretary, Mr. F. Le Gros Clark, at the headquarters of the committee, 19c, Eagle-street, W.C. 1.

Institute of Medical Psychology

A short course of lectures, on the Approach to the Psychoneuroses, for practitioners and medical students, will be held at the new premises of this institute, Malet-place, London, W.C., from June 18th to 29th. The lectures will be at 4.45, 5.45, and 8.15 P.M. daily, from Monday till Friday, and there will be demonstrations on Saturday, June 23rd, from 2.30–5 P.M. Further particulars may be had from the hon. lecture secretary at the institute.

University College Hospital

The report for 1933, the centenary year, shows a total of 8624 in-patients in the main (5542), the obstetric (1868), and the Royal Ear (1214) hospitals. There were 78,570 out-patients, 54,583 of whom attended the main hospital. The in-patients' average stay was 21·78 days, and their average statistical cost per head was £2 19s. 7d. There is "urgent need" for extending the child welfare and antenatal departments, and the provision of pay-beds "is hardly a less pressing necessity." A site in the near neighbourhood of the Obstetric Hospital is available for these extensions, which are estimated to cost £100,000. The policy of discouraging out-patient attendances for trivial complaints has reduced the number of general medical out-patients. In an endeavour to solve the problem of waiting in the out-patient departments, an intensive timing of patients from the time of arrival to the time of departure has been carried out in the main hospital over a period of three weeks, covering about 6000 cases. The returns show that, on an average, casualty patients are kept 1½ hours, old out-patients 1¼ hours, and new out-patients (whose histories have to be taken) 2¾ hours. These periods of waiting are not regarded as excessive.

West London Hospital

The report for 1933 presented to the annual meeting last week states that the extensions to the hospital, costing about £32,000, are to be begun. Three old houses on the Hammersmith-road, forming the south-eastern frontage of the hospital, will be demolished, which will enable a new building to be erected on the site. It will contain a new casualty department, with operation theatre, and X ray department. The Earl of Athlone, who presided, said that it was unfortunate that the urgently needed pathological laboratory must be left out of the scheme for the present. The money in hand for the extensions now amounts to £27,000.

Bolingbroke Hospital, Wandsworth Common

In the report for 1933 the governors lay urgent emphasis upon the need for replacing the old "mansion part" of the hospital, at a cost that will exceed £60,000. The 2127 new in-patients remained 19·23 days each on the average, and cost £3 per head per week; the statistical cost of each occupied bed was £145 19*s.* 11*d.* Although the 13,537 new out-patients were an increase of 413, their attendances decreased by 1108. The new system of inquiring into the financial status of out-patients "has proved in every way satisfactory." The pathological laboratory was opened during the year, and has been used to its full capacity. There was a deficit of £1082, caused almost entirely by the cost of renovations.

Appointments

GIFFORD, J., M.B., Ch.B. Edin., has been appointed Medical Superintendent, Prestwich County Mental Hospital.

MACKAY, W., M.B., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts for Strathdon, Aberdeenshire.

Vacancies

For further information refer to the advertisement columns

Ashton-under-Lyne, District Infirmary.—H.S. At rate of £150.
Bagdad, Royal College of Medicine.—Chair of Materia Medica.
Beckenham, Bethlem Royal Orchard, Monks Orchard.—Sen. Asst. Phys. £700.
Birmingham, Dudley-road Hospital.—Jun. M.O. At rate of £200.
Birmingham Maternity Hospital.—Res. M.O. and Reg. £200.
Brighton, Royal Sussex County Hospital.—H.S., and Cas. H.S. £150 and £120 respectively.
Burma, Rangoon Municipal Corporation.—Health Officer. Rs. 1300.
Burton-on-Trent, Bretby Hall Orthopædic Hospital.—Locum Res. Asst. M.O. At rate of £350.
Burton-on-Trent General Infirmary.—Cas. O. and H.P. £150.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Cardiff, Welsh National School of Medicine.—Demonstrator in Materia Medica, &c. £50.
Charing Cross Hospital Institute of Pathology, W.C.—Part-time Bacteriologist and Hæmatologist. At rate of £250.
Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.
Chesterfield, Walton Sanatorium.—Locum Res. Asst. M.O. At rate of £350.
Children's Hospital, Hampstead, N.W.—Res. M.O. At rate of £100.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Connaught Hospital, E.—Hon. Surgeon.
Dewsbury and District General Infirmary.—H.S. £150.
Dewsbury, Infectious Diseases Hospital.—Res. M.O. £200.
Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. At rate of £110.
Edinburgh Royal Colleg[illegible] Duncannon Fellowship for Medica[illegible]
Evelina Hospital for Sick [illegible] *E.*—H.P. At rate of £120.
Glasgow University.—Muirhead Chair of Medicine.
Gloucester, Gloucestershire Royal Infirmary, &c.—Res. H.P. and Res. H.S. Each at rate of £150.
Golden-square Throat, Nose, and Ear Hospital, W.—Hon. Surgeon. Also Hon. Asst. Surgeon.
Great Yarmouth General Hospital.—H.S. £140.
Hastings, Royal East Sussex Hospital.—Temp. Asst. Pathologist. 7 gns. per week.
Hendon Isolation Hospital.—Res. M.O., &c. £500.
**Hospital for Consumption and Diseases of the Chest, Brompton, S.W.*—Asst. in Pathology Dept. £350.
Hospital for Sick Children, Great Ormond-street, W.C.—H.P. and H.S. Each at rate of £100. Also Physician to Skin Department.
Hull Municipal Maternity Home and Infants' Hospital.—Ju Res. M.O. At rate of £100.
Hull Royal Infirmary.—Third H.S. At rate of £150.
Ilford, King George Hospital.—Cas. O. At rate of £130.
Kent and Canterbury Hospital.—H.S. At rate of £125.
Kingston and District Hospital.—Jun. Res. M.O. At rate £250.
Lancashire C.C., School Medical and Child Welfare Dept.—M. £800.
L.C.C.—Radiologist. £1500.
Leeds Public Dispensary and Hospital.—Hon. Surgeon.
Lincoln County Hospital.—Sen. H.S. At rate of £250.
Liverpool University.—Jun. Lecturer in Pathology Dept. £30
London Hospital, E.—Asst. Director of Med. Unit.
London University.—Chair of Obstetrics and Gynæcology. £200
Manchester Babies Hospital, Burnage-lane, Levenshulme.—Ju Res. M.O. At rate of £50.
Manchester, Christie Hospital and Holt Radium Institute, Will ington.—Res. M.O. At rate of £150.
Manchester Northern Hospital for Women and Children, Par place.—Jun. H.S. £100.
Manchester Royal Children's Hospital.—Asst. Surgeon. £50.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Northwood, Mount Vernon Hospital.—H.S. £150.
Norwich, Norfolk and Norwich Hospital.—H.P., H.S., and H. to Spec. Depts. Each £120.
Preston County Borough.—Asst. School M.O. £500.
Princess Beatrice Hospital, Earl's-court, S.W.—Clin. Asst. X Ray Dept.
Princess Louise Kensington Hospital for Children, St. Quinti avenue, N. Kensington, W.—H.P., and H.S. Each at ra of £100.
Queen Mary's Hospital for the East End, E.—Cas. O. At ra of £150. Also Two H.S.'s, H.P., Obstet. H.S., Res. Anæ thetist, and H.P. Each at rate of £120.
Queen's Hospital for Children, Hackney, E.—H.P. and Cas. Each at rate of £100.
R.A.M.C.—Commissions.
Rotherham Hospital.—H.P. £180.
Royal Free Hospital, Grays Inn-road, W.C.—Res. Cas. O. rate of £150. Res. Asst. Path. At rate of £75. Also H. for Ear, Nose, and Throat Beds, and Res. Anæsthetist.
Royal London Ophthalmic Hospital, City-road, E.C.—Hon. As Phys.
Royal Waterloo Hospital for Children and Women, Waterloo-roa S.E.—Hon. Clin. Asst.
St. Mark's Hospital for Cancer, &c., City-road, E.C.—Re Surg. O. At rate of £150.
St. Thomas's Hospital, S.E.—Chief Asst. to Dental Dept.
Salvation Army, Mothers' Hospital, Lower Clapton-road, E.— Jun. Res. M.O. At rate of £80.
Sheffield, Jessop Hospital for Women.—Two H.S.'s. Each rate of £100.
Shrewsbury Eye, Ear, and Throat Hospital.—H.S. At rate £225.
Southend-on-Sea General Hospital.—H.S. At rate of £100.
Swansea County Borough, Mental Hospital.—H.P. At rate £100.
West End Hospital for Nervous Diseases, Gloucester Gate, N.W.— Hon. Asst. Radiologist.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Ju Res. H.S. At rate of £100.
West London Hospital, Hammersmith-road, W.—H.P., H.S., an Res. Anæsthetist. Each at rate of £100.
Wolverhampton Royal Hospital.—H.S. for Ear, Throat, an Nose Dept. At rate of £100.
Worksop, Victoria Hospital.—H.S. At rate of £170.
York County Hospital.—Res. Anæsthetist and Asst. H.S. £15

* In our advertisement columns last week (p. 50) the da of the meeting of the Medical Committee of the Hospital f Consumption and Diseases of the Chest was inadvertent announced as June 30th. It is given correctly as June 20 in the advertisement appearing on p. 53 of our present issue.

Births, Marriages, and Deaths

BIRTHS

JOHNSON.—On May 15th, at Linden House, Romsey, Hants the wife of Dr. G. H. Johnson, of a son.

MARRIAGES

NEALE—SHARP.—On May 15th, at All Souls Church, Langham place, London, Albert Ezra Neale, M.D., of *Holland Park* to Vivien Irene, widow of Harold Sharp, of Northgate Warwick.

DEATHS

BARRS.—On May 12th at Wanstead, E.11, John Harry Barr F.R.C.S.I., Senior Surgeon of Connaught Hospita Walthamstow, in his sixty-ninth year.

BUCKLEY.—On May 15th, at Grosvenor-mansions, Buxton George Granville Buckley, M.D., late of Bury, aged 56.

SUTCLIFFE.—On May 9th, at Hill House, Tywardreath, Willia Sutcliffe, M.R.C.S., L.R.C.P. Lond.

TAYLOR.—On May 15th, at Park-circus, Glasgow, after a lon illness, James Taylor, F.R.C.S. Edin.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

LEFT-HANDEDNESS

SOME OF ITS ASSOCIATIONS

BY CHARLES J. MACALISTER, M.D. Edin., F.R.C.P. Lond.

CONSULTING PHYSICIAN TO THE LIVERPOOL ROYAL SOUTHERN HOSPITAL AND TO THE ROYAL LIVERPOOL CHILDREN'S HOSPITAL

IN 1642 Sir Thomas Browne discussing in his Religio Medici the doubts which have been cast upon certain Biblical statements by various authors confesses that he has perused them all and can discover nothing that may startle a discreet belief. Among these he says: "Whether Eve was framed out of the left side of Adam I dispute not because I stand not yet assured which is the right side of a man and whether there be any such distinction in nature." By far the largest number of left-handed people are perfectly normal physiologically, but there are abnormalities depending upon transposed, or to speak more correctly, imperfectly transposed function.

So far as we know all the lower animals are ambidextrous, and it is interesting to note that children up to the age of about two years also appear to use either hand indiscriminately. This is so marked that mothers get into the way of correcting their children by making them use the right hand when they manipulate with the left one, this educative factor being one of the popular explanations of the perpetuation of right-handedness.

The Origins of Right-handedness

That right-handedness is hereditary there can be no doubt, but how that characteristic was originally acquired is very difficult to explain, and as in the case of all unexplained problems, the number of theories which have been advanced is very considerable. I need not enumerate all of these, and many of them are far fetched and fantastic. One of the most popular arose from the impression of early man that in mortal combat wounds of the left chest were liable to be more fatal than those of the right, giving rise to the protection of the left side by a shield on the left arm, the right one thus becoming developed as a sword-arm.

Various observers have indicated that the left side of the brain develops somewhat earlier than the right one, and that the right side of the body therefore becomes earlier and more emphatically used owing to a greater supply of nerve force to its muscles, and that corresponding with this would come the earlier specialisation of the speech motor apparatus in the left Brocal convolutions.

Another suggestion put forward in the past was that the trend towards dextrality synchronised more or less with the development of writing by signs, and that it is just possible that a sign language preceded a spoken one. In this connexion it is interesting to remember that the natural sign language of the deaf and dumb must date from very ancient times. The real interest in it depends on its universality, a fact which was noted by George Dalgarno, an Aberdonian, who was headmaster of Elizabeth School, Guernsey, and later for many years at Oxford. Dalgarno in 1664 suggested that advantage should be taken of this fact to utilise it as a universal language, and he wrote a book on the subject entitled "Ars Signorum Vulgo Character Universalis."

Whatsoever the explanations of right- or left-handedness may be in the processes of evolution, there can be no doubt that they are hereditary; the great dominance of the inheritance being a right-handed one, and the distinctive features of this have led to each hand having its peculiar functions. The use of the knife in the right hand and the fork in the left one illustrates this, and also the specialised functions of the right and left hands in playing the violin, for instance, and other bimanual requirements. Notwithstanding this, the idea still exists that everybody ought to be ambidexter, or capable of being educated to be so, and on this basis the Ambidextral Culture Society was constituted. Its members believe that man, having originally been ambidextrous, and there being no anatomical or physiological reason for his being otherwise, one-handedness was simply an acquirement capable of being balanced and corrected. At one time, within my own recollection, this society was very active, but our knowledge of the functions of the brain, and more especially of the unilateral situation of the speech centre, has led to a dismissal of the suggestion that equi-handedness or equi-brainedness will ever become re-established, if it ever existed.

The Dominance of Right-handedness

All nations without exception have a dominance of right-handedness. Of the relative frequency of left-handedness in various nations I have no statistics, but in our own country the proportion ranges from 5 per cent. to 8 per cent., and there is reason for believing that in small communities it may be somewhat higher owing to the intermarriage of the people. Dr. W.W. Ireland in "Brain," 1880-81, vol. iii., p. 207, recorded some figures obtained from a teacher of the Sessional School at Larbert, where Ireland was superintendent from 1869 to 1879 of the Scottish National Institution for Imbecile Children. He estimated that among normal children in his district about 12 per cent. were left-handed. This is a much higher figure than maintains in the Liverpool council schools, in which I investigated the matter in 1920, and is probably related to the parochial population of a small place like Larbert where hereditary characteristics would tend to be amplified.

I recollect to have discussed with the late Prof. Thomas Glynn the reputed prevalence of left-handedness among criminals. I am not convinced that this has ever been confirmed, but in an article by C. Lombroso, in the *North American Review*, vol. v., p. 440, on left-handedness he stated that the percentage in this class was much higher than that in the normal population—viz., 13 per cent. among men and 22 per cent. in women, as compared with the 7 per cent. in men and 5 per cent. to 8 per cent. in women, in a total of 1029 normal members of society. However this may be, we certainly cannot infer from experience that the majority of left-handed people have a wicked strain in them, though it is interesting to recollect that the conventional use of the word "sinister" originated from a reputed association of the kind, and Lombroso mentioned that the people of Lombardy and Tuscany speak of an untrustworthy person as being left-handed. When left-handedness is inherited there can be no doubt that the large preponderance of right-handed people renders it extremely unlikely that the production of a pure left-handed strain is probable. An outcrop of left-handedness in a family is probably Mendelian in origin, owing to the union of hybrid individuals both having, say, a dominant right-handed inheritance with a repressed left-handed one. Where a definitely left-handed individual marries a right-handed hybrid possessing a repressed left-handed strain, the likelihood of there being left-handed progeny would of course be amplified.

Left-handedness and Transposition of the Viscera

It might be thought that complete transposition of the viscera would in every case be associated with a right-sided speech centre, but curiously this is not the case, there being a good many records of this condition where there has been right-handedness, although the majority of them have been left-handed.

M. Cachet, quoted by Pye-Smith in Guy's Hospital Reports, 1870, describes a case of transposition in a young woman who was right-handed during life; another case was recorded by M. Gery, and a third by Dr. B. S. Schultz; and in a case of a complete transposition recorded by Pye-Smith himself he had ascertained that the subject of the abnormality had been right-handed during life. These cases of course would be the equivalents of left-handedness in normal individuals. But left-handed people in a certain number of cases have undoubtedly left-sided speech centres, it being apparently unnecessary to have the speech centres transposed, although the dominant motor centres for the arm and leg are in the right hemisphere. This has been adverted to by many clinical observers who have commented on the fact that, in the majority of cases where left-handed people are the subject of apoplexy, giving rise to left hemiplegia, there is accompanying aphasia; and there have been instances where the hæmorrhage has been shown to involve the speech motor area in the right brain without interference with speech, thereby indicating that the speech centre had not been transposed. Bearing upon this there was an important paper in the *American Journal of Medical Sciences*,[1] written by Dr. Foster Kennedy, which deals with the causation of aphasia. This was a criticism of a paper by Pierre Marie and his colleague Moutier, written in 1908: "La théorie de la gaucherie cérébrale, pleine d'obscurities, contradite par les faits, ne peut servir à expliquer pour les partisans du centre de Broca les destructions de ce centre sans aphasie." This conviction arose from the circumstance that notwithstanding the indubitable evidence that in right-handed persons the speech centre is in the left Broca's area, there are certainly cases freely cited by Moutier of "right-handed right hemiplegics without aphasia, and also cases of left-handed left hemiplegics without any disturbance of their powers of conversation." The author's comment is that "these cases only impugn the theory of constant conjunction in any one subject of right-brainedness and left-handedness, or of left-brainedness and right-handedness." He suggests that the simple statement that a patient is right-handed is not adequate in some of the cases which he recalls, and he lays stress upon the necessity for investigating the question not only of a patient's handedness, but also of the prevailing type of handedness in his stock, which, as he states, throws some light on a very obscure chapter of neurological medicine. I freely quote his observations on this point:

His *first* case was one of a massive bomb injury to the right speech area and occipital lobes in a left-handed man without left-handed relatives or ancestry, and there was no aphasia. He never had any difficulty with speech. He was a man who was left-handed to an extreme degree. He reversed the usual position of the knife and fork, and, while he wrote with the right hand, he was equally able to do so with the left. The injury sustained was extensive, and with X rays the fragments of the grenade and of the driven bone were seen to have been flung through the cortex and embedded in the right occipital pole; if the speech centre had been in its normal position there should have been distinct disorder of that function.

His *second* case was one of a left-handed man, aged 36, suffering from embolic right-sided paralysis and aphasia, showing that the speech centre was in the left hemisphere. None of his near relatives or ancestors was known to be left-handed. Kennedy pointed to the fact that he was isolated as a left-handed person in a stock entirely right-handed.

A *third* case quoted was a completely left-handed man who had sustained a fracture involving the right speech area, with right middle meningeal hæmorrhage. Craniectomy had been performed, a bone injury of two by four inches having been made over the affected areas. There had been left hemiplegia which had recovered, but he occasionally suffered from severe left-sided convulsions. Despite his left-handedness, which was complete, except for writing, there had never been the slightest interference with the function of speech. This patient's relatives were all right-handed. He had lived, as had the first case recorded, as a member of a village community, in which in both instances were included many of their relatives. Each man was quite positive that he was the only left-handed member of the stock.

Another series of cases recorded by Kennedy is of right-handed individuals showing similar peculiar results from similar cerebral catastrophes. For instance, a right-handed girl suffering from severe Jacksonian convulsions confined to the left side of the body always followed by severe transient left hemiplegia with equally severe transient aphasia. The patient, herself right-handed, had a left-handed father and a left-handed mother. Another case was a young man suffering from right-sided subcortical Rolandic glioma, for which was performed a right subtemporal decompression. He had complete aphasia for ten days following the operation. He himself was right-handed, but he had two brothers both of whom were left-handed. Another case was that of a woman, aged 67, suffering from a cerebral hæmorrhage resulting in left hemiplegia and a considerable degree of sensory motor aphasia. She was right-handed, but her mother had been left-handed. She had a left-handed brother and a left-handed daughter.

Stammering

Bearing in mind these anatomical and physiological facts, and the Mendelian explanation of inherited left-handedness, I think we may be in a position to throw some light on the explanation of stammering, and some other conditions of muscular incoördination which have dawned as the outcome of clinical experience. The stammering associated with left-handedness has been the subject of recent correspondence in the lay press. Looking back one can recollect a considerable number of instances where this defect of speech has been transmitted by inheritance, sometimes in right-handed people as well as left-handed ones. In the former probably it is the result of a repressed left-handed strain, and in the latter of a repressed right-handed one, and in this connexion a study of the transposition of the speech centres in left-handed people is significant.

Right-handedness or left-handedness must be regarded as a kind of inherited physiological incoordination of function in which some specialisation has been acquired by one cerebral hemisphere as compared with the other, and it is from a study of such specialisation that we must try to elucidate the upsets which result in stammering and some other gross muscular ataxias. Hughlings Jackson in his writings on the speech centres directed attention to the very interesting barrel-organ expressions commonly observed in cases of aphasic hemiplegics, and he pointed out that these utterances often refer to the thought or verbal expression of the patient at the very commencement of the hæmorrhage. He instanced a case of a railway signalman who was struck down by an apoplexy when walking from his signal-box to the railway platform, along a line on which he knew that a train would presently pass. From the time of his stroke, although aphasic, he repeated over and over again the words, "I want protection." In my own experience a friend who was suddenly overwhelmed with an apoplexy of the left brain repeated over and over again the words, "I want some brandy," almost until the time of his death. These kinds of expressions, according to Hughlings Jackson, represent the last call of the patient before the destruction or putting out of action of the speech centre in the left Broca area. He advanced the explanation that although speech is initiated in the left centre, the corresponding centre in the right brain acts as an automatic one which, having picked up the message from its neighbour, pours it forth in the barrel-organ way described. Hughlings Jackson, from these observations, styled the left speech centre as the leading one and the right as an automatic one.

---

[1] Stock Brainedness, the Causative Factor in the So-called "Crossed Aphasias." Foster Kennedy, M.D., F.R.S. Edin., Amer. Jour. Med. Sci., 1916, p. 823.

May not all this throw some light on the relative functions of the two centres and help us in our explanation of stammering and some other grosser abnormalities? May not stammering of this type be due to an imperfect transposition of function in the centres of the two sides of the brain? If so, one can imagine that in a left-handed stammerer whose leading speech centre would be in the right brain there may be a recessed leading centre in the left brain, and also perhaps some imperfect transposition of the automatic centres, and that the stammering might result from a confusion of function on the two sides.

Cases of Congenital Aphasia

Bearing on this come those interesting cases of congenital aphasia, unassociated with any deafness, of which three have been under my personal observation. The *first* of these was a big well-developed girl of 13 who had never spoken properly, who was practically aphasic. At 3 years of age she was thought to say "Mama" and "Dada," and subsequently learned to say a few words imperfectly, but her real language was almost entirely composed of signs and gesticulations similar to those natural ones used by the deaf. She was an absolutely left-handed child of right-handed parents, but her maternal grandfather was left-handed. When she was developing, the left breast developed considerably before the right one. She was quite intelligent and had a wonderful memory. It was evident that she could not use her speech centres, and one speculates as to whether this marked incoördination was not related in some way to the right centre being unbalanced by some unusual development of function of the left one, thus giving rise to confusion of coördination. The *second* case was a child of 6 who, although aphasic, was absolutely bright and quite up to the standard of intelligence for her age; she was also left-handed and presented a collateral sinistral history. Although unable to speak she could hum tunes and try to sing without words. The *third* case was a boy, aged about 3, who had never spoken. He was right-handed, but came of a distinctly left-handed stock on the maternal side; the mother's brother and sister and his mother all being left-handed.

Fright Choreas: Epilepsy

I have had several cases of left-handed children who only began to stammer when an attempt was made to convert them into right-hand writers owing to confusion of the right and left centres. This leads me to mention another very interesting series of cases which, although clinically choreas, really represent a gross muscular ataxia. I refer to the so-called fright choreas. In looking over my records I find that I have notes of cases, of which 13 were right-handed, 15 left-handed, and 5 were markedly ambidexters. Every one of these cases presented an ancestral history of left-handedness. That is to say, that the tendency towards left-handedness in the case of the right-handed, and towards right-handedness in the case of the left-handed children. led to confusion of coördination resulting from partial or repressed transposition of the cerebral function; this had given no trouble until the upsetting of the balance had been brought about by fright or emotional causes. It is on these lines that I venture to suggest that we have the explanation of stammering, in its relation to left-handedness. There are, of course, types of stammering due to functional causes, unassociated with any history of left-handedness. These must not be confused with the cases to which I have referred.[2]

Physiological incoördination appertaining to handedness refers not only to the general motor system, but it has another curious association. There is normally a strong side and a weak side to the body, and this does not apply only to physical strength and dexterity, for it has a bearing upon vitality and upon susceptibility to disease. In a paper on Education and Coördination of Function[3] I pointed out that most deformities, such as club-foot and other malformations, are on the weaker left side, and so are a number of acquired diseases. I have over and over again demonstrated the fact that in right-handed children chronic fibroid bronchiectasis is almost invariably initiated on the left side, whereas its position is reversed when the patient is left-handed. At a meeting of the Association of Physicians of Great Britain and Ireland some years ago during a demonstration of a case of right-sided bronchiectasis, I remarked to the demonstrator, "Surely this boy must be left-handed, for I have seldom seen such a one in an ordinary right-handed person," and my conjecture turned out perfectly correct.

Ireland, whom I have already quoted, says left-handedness is not only common in epilepsy, but it is also more pronounced in this disease than in any other form of mental affliction, and Trousseau has remarked ("Clinical Medicine," Paris, 1868, vol. ii., p. 668), that the right and left sides are subject to different diseases; neuralgia, for instance, is more common on the left side of the chest than the right, and I have noted that chilblains and atrophy of the nails in cold weather are often more marked on the left hands than on the right. Wherefore this selective tendency for disease to attack the left side? It must be related to the greater vitality and strength of the right side. It has been suggested that the stronger right side is brought about by its having a more direct blood-supply than the left, but it is to be remembered that the supply to the right side of the brain is also more direct than it is to the left side, which rather annuls that theory. I have no explanation to offer unless it be that a lesser resistance on the weaker side has to do with the matter.

Conclusion

In conclusion I may just refer to some of the physical characteristics of left-handedness which are sometimes quite obvious. There is a degree of asymmetry, or, as it is often termed, hemiatrophia, in most people, the right side of the face and the right chest being rather more developed corresponding with the greater size and strength of the limbs. This muscular predominance is further observable in facial expression, the stronger side often acting a little more quickly or emphatically than the weaker, so that during smiling the angle of the mouth gets more elevated on the one side than on the other, and one eyebrow perhaps raises a little more than its neighbour. This asymmetry, together with the slightly larger orbit which is occasionally observable due to greater muscular tonicity, is not without its attractiveness. It gives rise to archness of expression which is a point in beauty. These characteristics are all transposed in the left-handed. Occasionally there is a greater growth of hair on the trunk of sinistral people on the left than on the right side, and regarding the hair of the head, it is sometimes easy to spot a left-hander because he parts his hair on the right and brushes it over to the left. When examining recruits during the war I frequently observed that, whereas the left testicle is the lower in a right-handed man, it is the higher in a left-handed one.

The subject of left-handedness and of the various conditions associated with it have interested me for many years, and the substance of this paper has been referred to in clinical and post-graduate lectures on several occasions.

---

[2] These cases and clinical experiences were referred to at a meeting of the Association of Physicians of Great Britain and Ireland at Edinburgh in 1923, and in an article on a Classification of Chorea in Relation to its Causes, Brit. Med. Jour., Nov. 8th, 1924.

THE LA TOJA SPA

THE island of La Toja, off the north coast of Spain, is well known for its copious hot salt springs (140° F.), which are used internally and externally for a variety of complaints. The water, besides the chlorides of sodium, calcium, and magnesium, contains a large proportion of iron and some bromide, arsenic, and silicates. Its composition makes it suitable for catarrhal dyspepsia and constipation and obesity, whilst the baths and natural muds are advised for chronic rheumatic, inflammatory, and exudative diseases of various kinds.

The opening of an installation in connexion with this spa at Sunderland House, Curzon-street, London, was announced recently in our columns. A visit to the installation by a specialist in spa therapeutics has resulted in the following note: "The natural salts and salt muds have been extracted from the source. The salts are prescribed internally in appropriate doses and for nasal douches, gargles, and inhalations. The baths are prepared from the salt iron mud and given usually with massage principally for rheumatic and skin affections. The effect is pleasant and stimulating to the skin and circulation. A medicinal soap and ointment have also been prepared from the La Toja waters, as well as a variety of toilet preparations. Whilst it cannot be expected that these preparations can reproduce the effects of the water in the fresh state, the baths should be of definite medical value in appropriate cases."

SANATORIUMS AND PUBLIC-HOUSES

THE report for 1933 of the Aargau group of sanatoriums makes it clear that the public-house is regarded in Switzerland as an inconvenient neighbour to a sanatorium. Previous reports have discussed the difficulties and their possible solution, and this report states that the governing body of the canton of Solothurn by resolution deprived the mountain inn Saalhöhe of its licence from Jan. 31st last because the licensee had not fulfilled an instruction to refrain from serving the sanatorium patients. It was left open to the licensee to carry on as a coffee-house from Feb. 1st, but even this permission is to be withdrawn should he continue to serve customers who can be recognised as sanatorium patients. Similarly, the inns Balmis and Barmel, which retain their licence, have to undertake not to serve sanatorium patients recognisable as such. The canton has refused an application for a licence to an inn at Breitmies. Their attitude to this question is not guided simply by regard for the sanatorium patients, but also for the other guests from the use of the same glass and crockery, the danger of infection not being met by the usual washing-up, unless supplemented by formal disinfection.

WHITFIELD STREET MOTHERS' CLINIC

Lord Moynihan has put his name to the first public appeal ever made on behalf of the Mothers' Clinic in Whitfield Street, Tottenham Court-road, London. First opened in Spring 1921, over 20,000 women have attended, and affiliated clinics are at work so far away as South Africa. Medical practitioners of many nationalities have visited the clinic and shown their appreciation of the teaching demonstrations given there.

EMPLOYMENT OF SURPLUS MILK.—Mr. JOHN CAMPBELL, Ph.D., writes to advocate the use of some of the surplus milk in bread-making. In Germany, he says, bakers are obliged to add at least 5 per cent. of milk to the dough, and in the U.S.A. and Canada powdered milk is used largely for the same purpose. Dr. Campbell does not suggest that the use of milk in bread-making could possibly replace the consumption of whole liquid milk in the school dietary, but he does think that in a pressing agricultural problem of this kind all possible fields of absorption should be exploited. The addition to white bread of milk even in small proportion would secure a proportion of high-quality proteins and phosphates at every meal and on every day.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, May 28th.

Odontology. 8 P.M. Annual General Meeting at the Royal College of Surgeons, Lincoln's Inn-fields, W.C. Sir Frank Colyer will show specimens received in the Museum during the past year.

TUESDAY.

Pathology. 8 P.M. Summer Meeting at Mill Hill. Imperial Cancer Research Fund, Stroud Laboratory: Demonstrations by W. Cramer, L. Foulds, E. S. Horning, R. J. Ludford, E. Vazquez-Lopez (Madrid), A. F. Watson, and A. F. Watson and M. Mitols. National Institute for Medical Research, Rhodes Farm: Demonstrations by G. W. Dunkin, J. McIntosh, and W. E. Gye and W. J. Purdy.

FRIDAY, June 1st.

Radiology. 7 P.M. Annual General Meeting.

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck-street, W.

THURSDAY, May 31st.—8 P.M., Annual General Meeting. Mr. H. A. Edgerton: Measurement of X Ray Quality by a Photographic Method. Mr. A. J. Minns: The Technical Aspects of Short Wave Therapy.

FRIDAY, June 1st.—Medical Meeting. 11 A.M., Visit to Cancer Hospital, Fulham-road, S.W. 5 P.M., Discussion of Cases. Dr. J. V. Sparks will give a short communication on Radiographic Demonstration of Calcification in Cardiac Valves.

A series of paper films by Dr. Sparks, with special reference to chest cases, will be on view at the B.I.R. on Thursday and Friday.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, May 28th, to SUNDAY, June 3rd.—MAUDSLEY HOSPITAL, Denmark-hill, S.E. Course in Psychological Medicine; afternoons.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Course in Dermatology; afternoons.—CITY OF LONDON HOSPITAL, Victoria Park, E. Course in Chest Diseases; all day.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Course in Gynæcology; all day.—LONDON LOCK HOSPITAL; 91, Dean-street, W. Course in Venereal Disease. afternoons.—ST. MARY'S HOSPITAL, Plaistow, E. Week-end Course in Medicine and Surgery; all day, Sat. and Sund.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Lecture on Functional Heart Disease, at 2.30 P.M. on Tues., by Dr. A. E. Clark-Kennedy.—LECTURE HALL, Manson House, 26, Portland-place, W. Debate on the motion "that in the absence of complications surgical interference in cases of gastric and duodenal ulcer is unnecessary." Principal speakers: Dr. A. F. Hurst and Mr. Mortimer Woolf for the motion, and Dr. Robert Hutchison and Mr. Herbert Paterson against the motion. Lord Moynihan of Leeds will take the chair. Wed., 8.30 P.M. (Open to all members of the medical profession.)

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.

THURSDAY, May 31st.—4.30 P.M., Dr. Allen Daley: Public Agencies which exist for the Prevention of Disease.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, May 30th.—4.30 P.M., Dr. T. Jenner Hoskin: The Cardiac Factor in the Choice of Anæsthetics.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

MONDAY, May 28th.—5 P.M., Dr. M. Sydney Thomson: Common Skin Diseases in Childhood.

WEDNESDAY.—5 P.M., Dr. J. A. Drake: Animal Parasites.

THURSDAY.—5 P.M., Dr. A. C. Roxburgh: Differential Diagnosis of some Common Skin Diseases.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH, Paddington, W.

THURSDAY, May 31st.—5 P.M., Dr. Leonard Colebrook: Control of Streptococcus Pyogenes Infections.

CHADWICK PUBLIC LECTURES.

TUESDAY, May 29th.—5.30 P.M. (at the Royal United Service Institution, Whitehall, S.W.), Dr. J. B. Orr: National Food-supply and Public Health.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, May 29th.—3.30 to 5 P.M. (at the General Hospital), Prof. *K. Douglas Wilkinson*: Use of Hypnotics.

FRIDAY, June 1st.—3.30 to 5 P.M., Dr. C. C. W. Maguire: Manifestations and Treatment of Arterio-sclerosis.

LEEDS GENERAL INFIRMARY.

TUESDAY, May 29th.—3.30 P.M., Mr. Broomhead: Backache.

GLASGOW POST-GRADUATE LECTURES.

WEDNESDAY, May 30th.—1.15 P.M. (at the Eye Infirmary), Dr. J. Marshall and Dr. J. B. Stewart: Eye Cases.

ADDRESSES AND ORIGINAL ARTICLES

THE RÔLE OF THE LIVER IN THE METABOLISM OF CARBOHYDRATE AND FAT*

By C. H. Best, M.D., D.Sc. Lond.,
F.R.C.P. Canada
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF TORONTO

I.—METHODS OF APPROACH TO THE PROBLEM

A TIME-HONOURED and very useful method of approach to a physiological problem such as that which I will discuss to-day is to remove the organ in question and to investigate the metabolic processes in the preparation thus produced.

In 1886 Minkowski removed the liver from geese, which are conveniently constructed for this operation, since the renal-portal vein anastomosing with the inferior vena cava by means of the circle of Jacobson provides a passage for the return of blood from the alimentary tract after the portal vein has been ligated. The liver can be removed without damaging the vena cava. It was soon realised, however, that certain metabolic changes in these birds are quite different from those of mammals, and the need for study of dehepatised mammals became even more apparent. The Eck fistula was introduced by the Russian surgeon whose name we associate with this procedure. The technique was popularised by Pavlov, and in his hands yielded very useful results in a field outside our immediate interest. The creation of this fistula is, of course, one of the essential steps in some of the techniques now used. The development of the modern method for complete removal of the liver is due very largely to F. C. Mann and his pupils. Some useful modifications of Mann's three-stage procedure have been introduced. We now prefer the single-stage operation recently described by Markowitz and Yater, who were for some time Mann's pupils, which utilises a number of steps introduced by various previous investigators. Completely dehepatised dogs have been and still are extremely useful in studies of carbohydrate and fat metabolism in which an unanæsthetised liverless preparation with central nervous system and pancreas intact is desired.

A large proportion of the information gained up to the present has been secured in animals dehepatised by Mann's three-stage operation. The problem in complete hepatectomy is the return of the portal blood, and that which normally flows through the hepatic portion of the vena cava, to the heart. The liver cannot be removed from mammals without including this portion of the vena cava. In Mann's method an artificial "caput medusæ," or pattern of collateral veins such as that seen on the abdomen in cases of chronic portal obstruction, is produced by gradually creating an impediment to the return of blood through the vena cava and portal vein. His first step is to make a reverse Eck fistula and to force caval blood through the liver by ligating the vena cava. An increased venous pressure is built up and anastomotic channels expand and carry much of the load. Some of these vessels are visible on the abdomen, but a large part of the blood may pass by way of the deep lumbar and azygos veins. Some six weeks later the portal vein is tied off and still further enlargement of the collaterals is produced. Hepatectomy may be performed at any subsequent time. This consists merely of ligating (1) the structures in the gastro-hepatic omentum, and (2) the sub-diaphragmatic vena cava. The liver can then be easily removed. The creation of the Eck fistula is the only difficult part of this operation. Markowitz and Soskin, working in Toronto, partially occluded the portal vein and vena cava by linen ligatures at one operation, and subsequently, after the collateral circulation had developed, obstructed these vessels completely and removed the liver. This two-stage method has provided useful preparations in the hands of many of us and enables hepatectomy to be performed in various small animals (cats, rabbits, guinea-pigs) in which the establishment of an Eck fistula is not practicable. In 1929 Firor and Stinson [1] described a one-stage operation for removing the liver. The vena cava was cannulated below the liver and the portal vein and cava were joined by a Y-shaped pyrex glass cannula below the caval cannula. These investigators introduced this very useful procedure of substituting a hard glass cannula of wide bore for the hepatic vena cava. There is no clotting in the cannula, and this procedure apparently introduces no new difficulties. One would, of course, prefer not to use this cannula if studies in the rate of clotting, &c., were being made in the dehepatised animal. Markowitz, Yater, and Burrows [2] utilise this pyrex glass cannula in their method which, in so far as my personal experience with it goes, offers an excellent means of obtaining completely dehepatised dogs for physiological studies. The blood loss and interference with the circulation are less than in the other procedures. I will attempt to describe this technique in as few words as possible.

The first step after the abdomen is opened is to expose the vena cava and portal vein by collecting the intestines in a fold of the duodenal mesentery which is then drawn to the animal's left side. The inferior vena cava is freed from its attachment at a point just below where it becomes buried in the liver. A stout ligature is tied around the cava and over a small brass rod, the function of which is to protect the vessel when this ligature is cut. The glass cannula is then inserted and secured. The occluded vena cava is then released. This very simple step is useful for complete removal of the liver in eviscerated preparations. The next step is to prepare the Eck fistula. This is a most interesting technique which in its present form is due in large part to Fischler and Schröder. The idea is to create a water-tight casement surrounding a cutting suture. The first row of sutures is laid and the cutting thread introduced, and the two vessels are sewn together over the line of the cutting thread by a second row of sutures. One then grasps the two ends of the cutting thread and saws through the adjoining walls of the two vessels. There is usually little or no hæmorrhage. The structures in the gastro-hepatic omentum are ligated and several ligatures are tied around the vena cava and the cannula above the liver. The liver is then removed in one piece.

Carbohydrate Metabolism in Dehepatised Animals

The dehepatised animals make a rapid recovery from the operation, and within an hour of the placing of the last suture they may run about and respond to call. At the end of the second hour, however, they are much less alert. The muscles may twitch. There may be generalised convulsions, coma, and death. This is the picture described by Mann and Magath and associated by them with hypoglycæmia. Incidentally, this description furnished the clue to the cause of the effects of an overdose of insulin. The improvement in the condition of these dehepatised animals brought about by the administration of sugar was the first convincing demonstration that

consciousness, the well-being and life of a mammal, depends on the maintenance of a certain tension of sugar in the blood. Bock and Hoffmann, and Pavy and Siau, had noted hypoglycæmia in anæsthetised dehepatised preparations, and numerous other observers found this to occur when the pancreas had also been extirpated (see Macleod, 1926).[3]

---

* Three lectures delivered for the University of London at University College on Jan. 11th, 15th, and 18th. Lectures II. and III. will appear in forthcoming issues.

The amount of dextrose necessary to maintain these animals in good condition varies somewhat, but the rate of injection should be such as to provide approximately one-quarter of a gramme per kilogramme per hour. If the liverless animal is exercised Mann and Magath found that the sugar requirement is considerably greater. Dehepatised, depancreatised dogs have also been found by Yater, Markowitz, and Cahoon to require large amounts of sugar. In general they need somewhat less than animals with the pancreas intact. Sugars other than dextrose are relatively ineffective, but I will not discuss this subject in detail.

These experimental results provide excellent evidence that one of the important functions of the liver is to manufacture sugar. In the absence of the liver, no means exist by which the concentration of the sugar of the blood can be raised other than by giving sugar. We know, of course, from Corkill's extension of Cori's work, that muscle glycogen may be broken down by adrenaline in functionally dehepatised animals, but the lactic acid formed is not changed into dextrose which is available to replenish the blood-sugar. It is well established that insulin accelerates the fall in blood-sugar in these preparations, but a discussion of that field is perhaps only on the fringe of my subject. It is dangerous to attribute the decreased susceptibility to insulin which is exhibited by these dehepatised animals (Markowitz, Mann, and Bollman) to any one factor, since so many metabolic disturbances have been produced. Himsworth's stimulating and closely reasoned argument in favour of the existence of an "insulin-kinase" merits serious consideration, but since there is as yet no direct evidence for the presence of this material in tissues a further discussion of the points he has raised is unnecessary. My reason for mentioning this work here is that the facts at present available have led Himsworth to suggest that this hypothetical "insulin-kinase" may be made in the liver.

Phosphate Metabolism in Dehepatised Animals

The effect on the inorganic phosphate of normal blood and urine which follows the injection of dextrose, or the production of hyperglycæmia by other means, apparently acts through liberation of insulin, since Markowitz, and more recently Waters, have been unable to detect the effect in depancreatised dogs. The responses of inorganic phosphate of the blood to insulin in the functionally dehepatised animal were studied by Best, Hoet, and Marks. The decrease is easily demonstrable in these preparations and therefore is certainly not wholly dependent on the liver. Dr. E. T. Waters, in my department, has been studying the effect of varying the rate of sugar injection in dehepatised dogs on blood phosphate. The results are essentially the same as those secured in functionally dehepatised cats. If dextrose is administered intermittently in large doses to these animals the inorganic phosphate may be reduced to and maintained at very low levels, and the conclusion might have been reached that absence of the liver was responsible for this state of affairs. If the necessary amount of dextrose to keep the blood-sugar approximately normal is supplied by continuous slow infusion the inorganic phosphate is within normal limits, and soon after dehepatisation the characteristic drop can be secured by increasing the rate of sugar infusion or by giving insulin.

One may remark here that the recent suggestion of Davis, Luck, and Miller,[4] that the part of the insulin molecule which affects blood phosphate is more resistant to soft X rays than that which produces hypoglycæmia, leaves one unconvinced that this is really the case.

Calorigenic Action of Adrenaline and the Liver

It is well known that adrenaline causes a rise in the resting metabolic rate of normal animals (Boothby), but as this effect apparently is not demonstrable in mammals after hepatectomy (Soskin) we may ascribe it in large part to an action on the liver. The discharge of dextrose formed from liver glycogen or from the lactate made available from muscle glycogen, and an increase in O_2 consumption of the liver itself are the factors to be considered, but their relative importance is undecided.

Respiratory Quotient of Dehepatised Animals

The resting respiratory quotient of the liverless animal is about 0·85. When glucose is administered intravenously it has been reported that the quotient rises promptly to approximately unity (Markowitz). These animals apparently breathe quite normally, but as blood and muscle CO_2 were *not investigated* judgment on the significance of this result must be reserved.

The respiratory quotient of the eviscerated preparation has been discussed recently by several workers (Irving; Kilborn; Peterson). There seems to be no doubt that it is usually *much lower than unity*, even when carbohydrate is administered. When insulin as well as carbohydrate is given, in our experience, the quotient is about 1. I will take this opportunity of bringing to your attention the findings of Irving, Foster, and myself, that the eviscerated spinal dog which is receiving both sugar and insulin has a quotient, corrected for changes in CO_2 of blood and muscle, of approximately 1. It is therefore, perhaps, permissible to calculate the sugar combustion of the eviscerated spinal animal receiving carbohydrate and insulin, on the basis that the O_2 is devoted exclusively to oxidation of carbohydrate (Table I. †). Irving, Foster, and I *feel that these balances are reasonably satisfactory*, and do not suggest the formation of carbohydrate compounds

other than glycogen by insulin under these particular conditions (suprarenals extirpated).

I may say that the determination of the respiratory quotient under any circumstances yields me very little satisfaction, since its interpretation is always in doubt. However, one must be allowed to make calculations such as these from experimental results obtained in a variety of ways. It may be slightly reassuring to some people that, when a preparation from which the principal organ, where conversions of food materials resulting in a low quotient might take place, has been removed and a carbohydrate plethora in the presence of an excess of insulin has been established, the ratio of $\frac{CO_2}{O_2}$ suggests either that carbohydrate oxidation exclusively is occurring, or that with or without some oxidation of carbohydrate sugar is being changed to fat, and some other process giving a lower quotient is also proceeding. The statement that there is no direct evidence of fat formation from sugar under these or similar conditions means nothing, since the amount of fat which might be formed could not be detected.

TABLE II.—*Spontaneous Hypoglycæmia or Increased Susceptibility to Insulin*

HYPERINSULINISM (Hyperactivity or tumour of islands of Langerhans)	INTERFERENCE WITH GLUCONEOGENESIS IN LIVER	HYPOFUNCTION OF ANTERIOR PITUITARY, ADRENALS, OR THYROID
	In Experimental Animals	
Hypertrophy after duct ligation. „ „ ant. pit. extracts ? No tumours carefully studied.	Hepatectomy. Interference with arterial blood flow. Poisoning { Phosphorus. Chloroform. Hydrazine. Synthalin, &c., &c. Deposition of fat.	Removal of pituitary (anterior lobe). Removal of adrenals. Removal of thyroid.
	Clinical Observations	
Cases of hyperplasia and hypertrophy. Cases of tumour.	Interference with arterial blood flow. Hepatitis. Carcinomata. Yellow fever. Acute yellow atrophy. Poisoning { Phosphorus. Carbon tetrachloride. Benzol. Chloroform. Synthalin, &c., &c.	Hypoglycæmia in so-called pituitary cachexia or Simmonds's disease. Hypoglycæmia in Addison's disease (some cases). Increased susceptibility to insulin after thyroidectomy.

Other causes of hypoglycæmia.—Excessive utilisation of sugar by muscles (dogs in treadmill, marathon runners). Exhaustion of carbohydrate reserves by thyroid feeding (with possibly also hyperactivity of islands of Langerhans) or, in some species, by fasting.

Spontaneous Hypoglycæmia

I may perhaps be allowed to interrupt this description of methods by referring briefly to the interesting subject of spontaneous hypoglycæmia. The rate of sugar production by the liver is the central factor in this problem. Under certain circumstances hypoglycæmia may be due to excessive utilisation of dextrose (prolonged muscular exercise) but is usually produced by a diminished rate of discharge of sugar from the hepatic vein. The three main factors in the production of this effect appear to be (1) damage to the liver cells, (2) excessive inhibition of gluconeogenesis by insulin, and (3) decreased gluconeogenesis attributable to hypofunction of the anterior pituitary, adrenals, or thyroid. I have listed under three headings some of the causes of experimental and clinical hypoglycæmia (Table II.). Direct interference with sugar formation in the liver quite appropriately occupies the central position. Some of the conditions which may produce this effect by damage to the liver cells have been listed, but no attempt has been made to make this list complete. A complete survey of this aspect of the subject has not to my knowledge been made. When there is no damage to liver cells, hypoglycæmia may be observed as a result of an excess of insulin, or, on the other hand, it may be produced by a subnormal activity of the anterior pituitary, the adrenals, or the thyroid. This question will be discussed from another point of view in the next lecture, but it is well established that removal of the anterior pituitary may result in hypoglycæmia (toads, dogs, and rabbits), that removal of the adrenal medulla increases the sensitivity of the animal to insulin, and that in some species hypoglycæmia attributable to adrenal cortex insufficiency is observed. The increased effect of insulin in thyroidectomised animals is also, of course, well known. Clinical counterparts of these experimentally produced conditions are also available. The evidence which is very rapidly accumulating suggests that the anterior pituitary is capable of exerting by direct action on the liver a greater effect on new formation of sugar than these other glands, and it may follow from this that hypofunction of this gland more frequently results in decreased sugar formation and hypoglycæmia. It will be obvious from this short discussion that spontaneous hypoglycæmia may be produced without there being any evidence of excessive insulin liberation from the pancreas. While it is possible for the clinician to determine in most cases whether or not the liver is severely damaged, and also to identify cases in which there is extensive involvement of the adrenals or thyroids, it is quite likely that hypofunction of the anterior pituitary might escape attention. It would be preferable to reserve the term "hyperinsulinism" for cases in which tumours of the islands of Langerhans or extensive hyperplasia and hypertrophy of these glands has been demonstrated (Harris [5]). As will be seen from Table III., which Dr. C. Aberhart has been good enough to prepare for me, in nearly half the cases of spontaneous hypoglycæmia in which an operation has been performed, no lesion of the pancreas (or

other than glycogen by insulin under these particular conditions (suprarenals extirpated).

I may say that the determination of the respiratory quotient under any circumstances yields me very little satisfaction, since its interpretation is always in doubt. However, one must be allowed to make calculations such as these from experimental results obtained in a variety of ways. It may be slightly reassuring to some people that, when a preparation from which the principal organ, where conversions of food materials resulting in a low quotient might take place, has been removed and a carbohydrate plethora in the presence of an excess of insulin has been established, the ratio of $\frac{CO_2}{O_2}$ suggests either that carbohydrate oxidation exclusively is occurring, or that with or without some oxidation of carbohydrate sugar is being changed to fat, and some other process giving a lower quotient is also proceeding. The statement that there is no direct evidence of fat formation from sugar under these or similar conditions means nothing, since the amount of fat which might be formed could not be detected.

TABLE II.—*Spontaneous Hypoglycæmia or Increased Susceptibility to Insulin*

HYPERINSULINISM (Hyperactivity or tumour of islands of Langerhans)	INTERFERENCE WITH GLUCONEOGENESIS IN LIVER	HYPOFUNCTION OF ANTERIOR PITUITARY, ADRENALS, OR THYROID
	In Experimental Animals	
Hypertrophy after duct ligation. ,, ,, ant. pit. extracts ? No tumours carefully studied.	Hepatectomy. Interference with arterial blood flow. Poisoning { Phosphorus. Chloroform. Hydrazine. Synthalin, &c., &c. Deposition of fat.	Removal of pituitary (anterior lobe). Removal of adrenals. Removal of thyroid.
	Clinical Observations	
Cases of hyperplasia and hypertrophy. Cases of tumour.	Interference with arterial blood flow. Hepatitis. Carcinomata. Yellow fever. Acute yellow atrophy. Poisoning { Phosphorus. Carbon tetrachloride. Benzol. Chloroform. Synthalin, &c., &c.	Hypoglycæmia in so-called pituitary cachexia or Simmonds's disease. Hypoglycæmia in Addison's disease (some cases). Increased susceptibility to insulin after thyroidectomy.

Other causes of hypoglycæmia.—Excessive utilisation of sugar by muscles (dogs in treadmill, marathon runners). Exhaustion of carbohydrate reserves by thyroid feeding (with possibly also hyperactivity of islands of Langerhans) or, in some species, by fasting.

Spontaneous Hypoglycæmia

I may perhaps be allowed to interrupt this description of methods by referring briefly to the interesting subject of spontaneous hypoglycæmia. The rate of sugar production by the liver is the central factor in this problem. Under certain circumstances hypoglycæmia may be due to excessive utilisation of dextrose (prolonged muscular exercise) but is usually produced by a diminished rate of discharge of sugar from the hepatic vein. The three main factors in the production of this effect appear to be (1) damage to the liver cells, (2) excessive inhibition of gluconeogenesis by insulin, and (3) decreased gluconeogenesis attributable to hypofunction of the anterior pituitary, adrenals, or thyroid. I have listed under three headings some of the causes of experimental and clinical hypoglycæmia (Table II.). Direct interference with sugar formation in the liver quite appropriately occupies the central position. Some of the conditions which may produce this effect by damage to the liver cells have been listed, but no attempt has been made to make this list complete. A complete survey of this aspect of the subject has not to my knowledge been made. When there is no damage to liver cells, hypoglycæmia may be observed as a result of an excess of insulin, or, on the other hand, it may be produced by a subnormal activity of the anterior pituitary, the adrenals, or the thyroid. This question will be discussed from another point of view in the next lecture, but it is well established that removal of the anterior pituitary may result in hypoglycæmia (toads, dogs, and rabbits), that removal of the adrenal medulla increases the sensitivity of the animal to insulin, and that in some species hypoglycæmia attributable to adrenal cortex insufficiency is observed. The increased effect of insulin in thyroidectomised animals is also, of course, well known. Clinical counterparts of these experimentally produced conditions are also available. The evidence which is very rapidly accumulating suggests that the anterior pituitary is capable of exerting by direct action on the liver a greater effect on new formation of sugar than these other glands, and it may follow from this that hypofunction of this gland more frequently results in decreased sugar formation and hypoglycæmia. It will be obvious from this short discussion that spontaneous hypoglycæmia may be produced without there being any evidence of excessive insulin liberation from the pancreas. While it is possible for the clinician to determine in most cases whether or not the liver is severely damaged, and also to identify cases in which there is extensive involvement of the adrenals or thyroids, it is quite likely that hypofunction of the anterior pituitary might escape attention. It would be preferable to reserve the term "hyperinsulinism" for cases in which tumours of the islands of Langerhans or extensive hyperplasia and hypertrophy of these glands has been demonstrated (Harris [5]). As will be seen from Table III., which Dr. C. Aberhart has been good enough to prepare for me, in nearly half the cases of spontaneous hypoglycæmia in which an operation has been performed, no lesion of the pancreas (or

consciousness, the well-being and life of a mammal, depends on the maintenance of a certain tension of sugar in the blood. Bock and Hoffmann, and Pavy and Siau, had noted hypoglycæmia in anæsthetised dehepatised preparations, and numerous other observers found this to occur when the pancreas had also been extirpated (see Macleod, 1926).[3]

The amount of dextrose necessary to maintain these animals in good condition varies somewhat, but the rate of injection should be such as to provide approximately one-quarter of a gramme per kilogramme per hour. If the liverless animal is exercised Mann and Magath found that the sugar requirement is considerably greater. Dehepatised, depancreatised dogs have also been found by Yater, Markowitz, and Cahoon to require large amounts of sugar. In general they need somewhat less than animals with the pancreas intact. Sugars other than dextrose are relatively ineffective, but I will not discuss this subject in detail.

These experimental results provide excellent evidence that one of the important functions of the liver is to manufacture sugar. In the absence of the liver, no means exist by which the concentration of the sugar of the blood can be raised other than by giving sugar. We know, of course, from Corkill's extension of Cori's work, that muscle glycogen may be broken down by adrenaline in functionally dehepatised animals, but the lactic acid formed is not changed into dextrose which is available to replenish the blood-sugar. It is well established that insulin accelerates the fall in blood-sugar in these preparations, but a discussion of that field is perhaps only on the fringe of my subject. It is dangerous to attribute the decreased susceptibility to insulin which is exhibited by these dehepatised animals (Markowitz, Mann, and Bollman) to any one factor, since so many metabolic disturbances have been produced. Himsworth's stimulating and closely reasoned argument in favour of the existence of an "insulin-kinase" merits serious consideration, but since there is as yet no direct evidence for the presence of this material in tissues a further discussion of the points he has raised is unnecessary. My reason for mentioning this work here is that the facts at present available have led Himsworth to suggest that this hypothetical "insulin-kinase" may be made in the liver.

Phosphate Metabolism in Dehepatised Animals

The effect on the inorganic phosphate of normal blood and urine which follows the injection of dextrose, or the production of hyperglycæmia by other means, apparently acts through liberation of insulin, since Markowitz, and more recently Waters, have been unable to detect the effect in depancreatised dogs. The responses of inorganic phosphate of the blood to insulin in the functionally dehepatised animal were studied by Best, Hoet, and Marks. The decrease is easily demonstrable in these preparations and therefore is certainly not wholly dependent on the liver. Dr. E. T. Waters, in my department, has been studying the effect of varying the rate of sugar injection in dehepatised dogs on blood phosphate. The results are essentially the same as those secured in functionally dehepatised cats. If dextrose is administered intermittently in large doses to these animals the inorganic phosphate may be reduced to and maintained at very low levels, and the conclusion might have been reached that absence of the liver was responsible for this state of affairs. If the necessary amount of dextrose to keep the blood-sugar approximately normal is supplied by continuous slow infusion the inorganic phosphate is within normal limits, and soon after dehepatisation the characteristic drop can be secured by increasing the rate of sugar infusion or by giving insulin.

One may remark here that the recent suggestion of Davis, Luck, and Miller,[4] that the part of the insulin molecule which affects blood phosphate is more resistant to soft X rays than that which produces hypoglycæmia, leaves one unconvinced that this is really the case.

Calorigenic Action of Adrenaline and the Liver

It is well known that adrenaline causes a rise in the resting metabolic rate of normal animals (Boothby), but as this effect apparently is not demonstrable in mammals after hepatectomy (Soskin) we may ascribe it in large part to an action on the liver. The discharge of dextrose formed from liver glycogen or from the lactate made available from muscle glycogen, and an increase in O$_2$ consumption of the liver itself are the factors to be considered, but their relative importance is undecided.

Respiratory Quotient of Dehepatised Animals

The resting respiratory quotient of the liverless animal is about 0·85. When glucose is administered intravenously it has been reported that the quotient rises promptly to approximately unity (Markowitz). These animals apparently breathe quite normally, but as blood and muscle CO$_2$ were not investigated judgment on the significance of this result must be reserved.

The respiratory quotient of the eviscerated preparation has been discussed recently by several workers (Irving; Kilborn; Peterson). There seems to be no doubt that it is usually much lower than unity, even when carbohydrate is administered. When insulin as well as carbohydrate is given, in our experience, the quotient is about 1. I will take this opportunity of bringing to your attention the findings of Irving, Foster, and myself, that the eviscerated spinal dog which is receiving both sugar and insulin has a quotient, corrected for changes in CO$_2$ of blood and muscle, of approximately 1. It is therefore, perhaps, permissible to calculate the sugar combustion of the eviscerated spinal animal receiving carbohydrate and insulin, on the basis that the O$_2$ is devoted exclusively to oxidation of carbohydrate (Table I. †). Irving, Foster, and I feel that these balances are reasonably satisfactory, and do not suggest the formation of carbohydrate compounds

liver) has been detected. While it is possible, as has been suggested, that a small tumour might escape attention, it is by no means clear that the history of the development of the surgical treatment of hyperthyroidism will be repeated in this instance. From the point of view of the physiologist it would appear more rational to attempt to increase gluconeogenesis by administering a suitable extract of the anterior lobe of the pituitary, if this should be made available, rather than to attempt to remove sufficient pancreas so that the amount of insulin liberated is reduced to compensate for an inadequate supply of the diabetogenic substance of the anterior pituitary. The evidence which suggests that this diabetogenic substance acts in part at least by a direct stimulation of the liver to produce sugar will be reviewed in the next lecture. The rational treatment of these cases at present consists in: (1) Supplying carbohydrate. (2) Stimulating new production of carbohydrate. Liberation of stored glycogen can only have a transient effect. Some success has been secured by thyroid therapy, but here the increased production of sugar by the liver may be negatived by the increased consumption of sugar which thyroxine also produces. (3) By the surgical removal of a tumour, if it should be present. To this list there may shortly be added the use of a potent diabetogenic substance prepared from the anterior pituitary. If, as may well be the case, the therapeutic effects of the extract from the anterior lobe are not satisfactory, the clinician will probably be forced in severe cases of spontaneous hypoglycæmia to recommend excision of a large part of the pancreas irrespective of whether or not the presence of adenoma is suspected.

Fat Metabolism in Dehepatised Animals

There is considerable evidence that the liver plays an important rôle in the metabolism of fat. Among his many contributions to physiology, the late Prof. Embden (Embden and Kalberlah)[6] noted that the perfused liver formed acetone from straight chained fatty acids with an even number of carbon atoms. This provided excellent support for Knoop's theory of β-oxidation. The acids with an odd number of carbon atoms apparently are not naturally occurring and therefore need not be considered.

Any worth-while discussion of β-oxidation with a consideration of the contributions of Dakin, and the more recent ones of Raper and his collaborators, and of Quick, would require a large part of the lecture hour and should be discussed by someone with greater experience in that field than I. Since ketone bodies exist in small quantities in the blood of normal animals, there is an increasing tendency to consider that these are normal products of the breakdown of fatty acids. The experimental results available at present suggest, but do not prove, that the ketone bodies are made exclusively by the liver. If hepatectomy is performed on a depancreatised dog which is exhibiting a profound ketosis, the concentration of these substances in the blood begins to fall immediately (Chaikoff and Soskin).[7] This finding suggests that the ketosis of diabetes is not chiefly due to diminished utilisation of ketone bodies, but rather to excessive production, as is apparently the case with sugar. When sodium aceto-acetate is administered intravenously to dehepatised dogs, large quantities of beta-hydroxy-butyric acid appear in the blood stream. The concentration of this latter substance diminishes rapidly. When the lævo salt of beta-hydroxy-butyric acid is injected into these animals this substance is utilised without the appearance of aceto-acetic acid. (Markowitz, unpublished observations.)

The time is not yet ripe for an attempt to correlate these findings with the results of liver perfusions in which the ketone bodies have been added to the circulating blood or with those of in-vitro experiments on the oxidation of the fatty acids.

The evidence that dehepatised animals utilise fat normally is largely based on the carefully controlled experiments of Drury and McMaster.[8] The fate of their interpretation, like that of many another contribution, depends on the meaning which may be attached to an R/Q which is in the neighbourhood of 0·7. The fact that the quotient in fat fed animals remains at this low level after removal of the liver presumably indicates either that resting muscle tissue utilises fat directly or that sugar is formed from fat in the liverless preparation. The former interpretation has the advantage of simplicity, and while the frequent attempts to obtain direct evidence have thus far consistently failed, the great difficulties inherent in this type of experiment should of course be appreciated.

Liver Function Tests

The interpretation of many of the liver function tests has been quite recently discussed from a physiological point of view by Green, Snell, and Walters, by Mann and Bollman,[9] and by Poulsson. It is perhaps worth while emphasising again that the liver may respond normally to several of the function tests and yet yield an abnormal result to another one. One difficulty, of course, in the interpretation of the results of these tests is the uncertainty that we are dealing with the function of the liver cells alone. The second difficulty is that many of these liver function tests may yield a normal result when only a fraction of the normal amount of liver tissue is present in the animal. From the physiological point of view the uric acid function test has certain advantages. Uric acid is apparently dealt with only by the liver. The first abnormality Mann noted, when the amount of liver tissue was reduced gradually by repeated lobectomies in animals provided with an Eck fistula, was accumulation of uric acid in the blood. In his work on dogs he obtains the most satisfactory results with the uric acid tolerance test. MacLean and I have recently had some experience with the uric acid, the galactose, the bilirubin, and the bromsulphalein tolerance tests. The uric acid test usually produces no disturbance in diabetic dogs, and it appears to be as useful as any under the conditions of our experiments. There have been cases, however, in which the uric acid curve was normal, but either the disappearance of bromsulphalein or galactose was definitely retarded. The situation at present is that several of the tests should be conducted before the conclusion is reached that no abnormality is demonstrable. Glucose and fat tolerance curves may also be expected to give some idea of the condition of the liver cells, but here again, of course, the action of the liver is only one of the many factors which must be considered. A few remarks may be made about these procedures before returning to a very brief consideration of the more specific liver function tests.

GLUCOSE TOLERANCE CURVES

One is becoming more and more convinced that the procedure frequently followed in conducting glucose tolerance tests places far too little strain on the mechanisms involved. It is preferable to determine how much dextrose an animal can assimilate without exhibiting a marked hyperglycæmia or glucosuria (Woodyat) rather than merely to administer one dose of sugar intravenously and to study the rate of decrease of the blood-sugar. If the usual method is adhered to, two tests in quick succession have been reported to reveal an abnormality not apparent in the results of the first test. If the sugar is administered by the oral route the interpretation of the results of the tests may, under certain circumstances, be further complicated by the fact that in the normal intestine of the rat and the dog, and probably in other animals, dextrose absorption apparently is practically always proceeding at a fixed rate. It might, therefore, be difficult to demonstrate an increased tolerance even if it should exist, and for the same reason considerable decrease might take place before it would be obvious. If the intestine is not normal still another variable is introduced.

FAT TOLERANCE CURVES

As far as I am aware no one has been able to obtain consistent fat tolerance curves in experimental animals. Miss Huntsman and I have tried to secure uniform results in dogs. The fat which we wished to study yielded so little lipæmia that further attempts to obtain a consistent curve after the administration of this material were abandoned. Olive oil, cream, and various other mixtures of fatty substances, of course, produce a definite lipæmia which may disappear within six to eight hours. When, however, an attempt was made to produce comparable curves in the same animal with the same amount of oil on different occasions, under apparently standard conditions, little success was secured. Fluoroscopic investigations showed us that one cause of these irregular results was variation in the rate at which the fat leaves the stomach. We resorted to a highly unphysiological procedure in an attempt to surmount this difficulty. Mann-Bollman fistulæ were created in several animals and the olive oil was introduced through these directly into the duodenum. Here again, while two curves might be comparable, the third would perhaps be grossly divergent. Since our desire was to study the effect of choline on the absorption of fat and not at that time to conduct a research on fat tolerance curves, we abandoned the attempt in the hope, which has not as yet been realised, that direct determination of the fat remaining in the intestine of small animals at various intervals after administration might yield more consistent results.

THE OTHER FUNCTION TESTS AND THE FAT AND CARBOHYDRATE RESERVES OF THE LIVER

If one is interested primarily in the effectiveness of the liver as a whole in the performance of certain duties, obviously the only method of study is to place a strain on this mechanism and to investigate the response. If one is interested, however, in the state of the carbohydrate or fat content of the liver cells, the only reliable procedure is to obtain a specimen of the liver tissue and to conduct chemical and histological studies. It is desirable to correlate the chemical with the histological findings and not to rely on either alone.

It has been reported by Harding that a diet rich in fat causes a rise in the level of blood uric acid and an increased excretion of this substance in the urine. This may be due in part to an effect on the kidney, but there is some evidence that such a diet diminishes the power of the liver to remove bromsulphalein from the circulation (Rosenthal). In the normal animal some 90 per cent. of the recommended intravenous dose of this dye is rapidly excreted in the bile. The well-established effects of diets high in fat or carbohydrate tolerance might be discussed here but the extent to which the liver is involved in this very definite change is at present unknown. While it is possible that under certain circumstances mere mechanical effects of crowding the liver cells with fat may interfere with their function in certain species, it is important to remember that in other organisms it is apparently normal to have very large percentages of fat present. Whether the very high fat content of the liver in hibernating mammals plays any part in their decreased metabolic rate may be worth considering. A slight increase in liver fat in an animal under certain conditions may be of considerable pathological significance, while a more extensive deposition under other circumstances apparently is not associated with any abnormality of liver function.

The relationship existing between the glycogen content of liver cells and their function furnishes an interesting subject for discussion. It is true that almost complete absence of glycogen is compatible (for a short time) with an increased activity of liver cells. This is seen in diabetic animals four or five days after the supply of insulin has been discontinued. The glycogen content is very low, the liver is producing large amounts of dextrose, and liver function tests may give normal results. In general, of course, conditions which exhaust liver glycogen encourage the development of fatty changes in the liver cells. I will not take time to review the experimental and clinical evidence that the presence of glycogen in the liver cells renders the organ more resistant to various deleterious influences—anæsthesia, arsenicals (or bacterial products), phloridzin, &c. It will be appreciated that glycogen deposition in the liver is only one of the effects produced by sugar infusion. It is possible that the increased amount of insulin liberated may decrease gluconeogenesis—i.e., decrease the activity of the liver cells. In other words, the presence of glycogen may be incidental.

If one is interested both in liver function and the state of the carbohydrate and fat contents of the cells, MacLean and I have found that a useful procedure to follow in dogs is to conduct the uric acid and the bromsulphalein tolerance tests and to correlate the results of these with those of chemical and histological studies made on a specimen of liver obtained at biopsy. In dogs it is preferable, as Mann has pointed out, to tie off the pedicle of a lobe and to remove the lobe completely. No tissue that is likely to become necrotic should be allowed to remain. We have used this technique frequently with success even in diabetic dogs with very fatty livers. Morphine and local anæsthesia or intravenous amytal may be used when one is primarily interested in liver carbohydrate, but nitrous oxide or ether are satisfactory, as far as is known, when only the fat content and histological appearance are under investigation. Under favourable conditions surgeons do not hesitate to remove a small piece of human liver for histological investigation, and happily chemical studies are also beginning to be made on this material.

Margin of Safety of the Liver and Restoration of Liver Tissue

These subjects are too broad to be considered in any detail at the present time, but far too important to be entirely ignored. The margin of safety which the liver possesses may be illustrated by the fact that when 80 per cent. of the liver has been removed from dogs the fasting blood-sugar is normal, although other evidence may betray the existing hepatic insufficiency. It is for this reason probably that hypoglycæmia is observed only as a terminal phenomenon in clinical cases of yellow fever and acute yellow atrophy of the liver, in which histological studies of the liver cells make an investigator marvel that the tissue can perform any function whatever.

The second important point to realise is that liver tissue apparently possesses a tremendous capacity for compensatory increase in bulk (Fishback[10]).

when injected into pregnant women. It may be of interest to note that in the case mentioned by Waldstein he found that œstrin was diminished in the blood and urine, as well as in the placenta, at parturition. Large doses injected into animals will bring on abortion, as shown by Parkes.[17] If injected with Pitocin abortion came on in from 1 to 6 hours, but with œstrin not until 36 to 48 hours after injection.

It is interesting to note that a fresh set of corpora lutea can be added to the ovaries as desired, and in the rabbit ovulation can be induced at any stage of pregnancy by a single injection of extract of anterior lobe or the urine of a pregnant woman. These experiments were undertaken by Franklin S. Snyder[18] in an attempt to determine the rôle of the corpora lutea in parturition. Although the ovaries may be absent it may show that certain hormones injected into the circulation may influence uterine contraction.

UTERINE EXCITATION

Reviewing all that has been done with regard to these experiments, there seems to be strong evidence in favour of some hormone of an oxytocic nature being the cause of the uterine excitation starting labour. The source of this hormone has yet to be discovered. Although animal experiments suggest a synergistic action between œstrin and pituitrin, it is well known that the isolateduterus bathed with œstrin is more sensitive to pituitrin as shown by the increased contraction, but there is no evidence that œstrin is the cause of uterine contraction in labour. It was shown by Dodds that enormous doses of œstrin would be necessary to have any important effect in starting labour. The theory that in early pregnancy œstrin is held in check by the luteinising factor in the ovary, placenta, and anterior hypophysis, and that the inhibiting action is released with the maturity of pregnancy cannot be accepted, for we know that pregnancy can go to term without either the ovary or the pituitary, unless it is presumed that some other secretion, as suggested by Halban, might exert action similar to the ovaries. Thornwell Witherspoon[19] administered ovarian follicular fluid in the form of theelin in various doses to ten pregnant women at term, and labour occurred within 36 hours in two cases only. The same hormone in the form of amniotin or progynon was given alone or in combination with pituitrin or pitocin in various doses and at different times to 30 women at term, and only seven were delivered in 36 hours. To test whether there might not be an oxytocic factor present in the blood of parturient women, 25 c.cm. of blood taken from women in hard labour were injected into three women at term; one was delivered in 11 hours. In the case of 45 full-term women in only 22·2 per cent. labour was apparently induced by hormonal injections. The fact that labour started so quickly after the injection of blood from a woman in labour is interesting, for it must approach the normal oxytocic material, but it must be remembered that hormonal injections are not the only ones which will produce oxytocic material in the blood. What we have to discover is something sufficiently powerful to excite the uterine ganglia to produce contractions. Œstrin is certainly of no use, and it is obvious that enormous doses would be required, considering that there is already a large amount of this material circulating in the blood at term. Blau and Hancher[20] proved that the intravenous injections of various extracts besides that of the ovary (spleen, liver, testes, &c.) also produced oxytocic substances in the cerebrospinal fluid. Notwithstanding all the time and labour bestowed on experiments with a view to discovering from a maternal source the constitution of the material in the blood which acts on the uterine ganglia, nothing has been definitely established. And here it may be remarked that these experiments have been carried out with a view to determining the presence of some oxytocic material in the blood-serum, renal secretion, and cerebro-spinal fluid, as well as the chemical, physical, and spectroscopic investigation of the blood of parturient women.[21]

THE FŒTUS

Turning to the fœtus, we know that the blood, as it comes from the umbilical cord, is entirely different from that of the maternal circulation. This must be accounted for by secretions from internal glands being poured into it during its passage. The blood in the umbilical vein passes directly to the undersurface of the liver, where divisions go to the left lobe and to the lobus quadratus and lobus spigelli. Therefore the first changes must take place in the liver, which may contain many hormones. We do not yet know enough about the secretions of the fœtal internal secretory glands, and investigation is obviously extremely difficult. The thyroid has a colloid-like secretion at four and a half months.[22] The suprarenals contain adrenaline at 16 months, and the pituitary gland shows an active principle at eight months. Therefore all these glands are acting at maturity. It is certainly remarkable that the fœtus should have such a large liver,[23] weighing one-eighteenth part of the total body-weight of the fœtus. The blood of the fœtus differs materially from that of the mother; there is an excess of non-volatile acid compounds—an acidosis of birth.[24]

After consulting many authorities, Karnitski[25] in his review states that the iron and hæmoglobin contents are greater in the fœtal than in the maternal blood, and that nucleon or phospho-carnic acid is found twice as great in amount in the fœtal blood as in that of the placenta. Joseph[26] has assayed the urine of new-born infants and reported certain factors, and that no hormone was present after the fifth day. When a child is born, the intense contractions of the uterus cease. From a series of experiments, it has been shown that the blood taken from the umbilical cord immediately upon birth contains substances which promote the activity of the uterus in a guinea-pig to a greater extent than other blood, or that of the mother.[27] There is very little theelin in extracts of embryo, although it has been demonstrated in the umbilical cords of human fœtuses at term.[28]

CONCLUSION

In conclusion, I may say that notwithstanding numerous experiments carried out during this research on the blood, tissues, secretions, &c., of parturient women, they have failed, as already mentioned, to yield convincing results.

With regard to the fœtus, Dodds says: "A very careful study of the tissues of the fœtus has been made in the attempt to trace substances capable of initiating the changes associated with labour. Up to the present these have not met with success, but it is felt that continued careful study of such extracts may open up a new line of approach."

In my own opinion there is a possibility that in the future more delicate biochemical tests may be forthcoming which will throw new light upon this research, and enable us to prove definitely the actual constituents of maternal and fœtal blood. Much time and labour have hitherto been devoted to the pregnant and parturient woman. In future, more attention will be paid to the fœtus. I am glad to say that a fresh set of experiments is about to be undertaken, the results of which will be published later, for this research will continue. If success should be achieved it need hardly be said that it will be a lasting benefit to countless generations to come.

CHANGES IN THE CENTRAL NERVOUS SYSTEM DUE TO ELECTROCUTION

BY E. A. BLAKE PRITCHARD, M.D. Camb., M.R.C.P. Lond.

ASSISTANT IN THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL ; ASSISTANT PHYSICIAN, HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE ; CONSULTING NEUROLOGIST, LONDON COUNTY COUNCIL

THE pathological changes that are found in the brains of persons dead from electric shock, whether by lightning stroke or by accidental contact with high-tension conductors, fall into two main groups.

There are those changes that result from any form of severe mechanical damage of the skull and of its contents, and those changes that are found only in fatal cases of electrocution. The former group can in many cases be accounted for by a fall or a blow received at the time of the accident, and no other explanation of their occurrence is necessary. The latter group of changes are peculiar to this (electrical) form of damage and their explanation is therefore to be sought in some property of this particular variety of injury—i.e., in terms of some property of electrical discharges.

These lesions of the central nervous system which are peculiar to the brains of fatally electrocuted persons are as follows :—

(1) The cerebro-spinal spaces are dilated ; in the main subarachnoid spaces there is wide separation of the pia from the arachnoid and the perivascular spaces are often greatly distended.

(2) There are abnormal holes or spaces in the brain due both to rents or fissures in its substance and to the local separation, by splitting apart, of adjacent cortical layers.

(3) The ganglion cells are damaged with unequal severity in different groups, but in a way which points in many cases to their disruption in a peculiarly sudden and violent manner.

(4) The blood-vessels are severely and extensively damaged, especially the larger ones at the base of the brain ; their muscular coat suffers most and is sometimes *completely ruptured.*

These lesions have been found after every precaution has been taken to avoid similar distortion of the tissues due to faulty fixation and staining methods. Their occurrence has always hitherto been explained in one of three ways—i.e., as being due either to the heating effect, to the electrolytic effect, or to the mechanical effect of an electric current.

HEATING EFFECT OF THE CURRENT

In a large number of cases of fatal electrocution it is certain that the current passing through or over the body is sufficient to produce somewhere in its path enough heat to account for severe damage to the tissues.

Thus, if we consider the case of legal electrocution as carried out in America—in which 2300 and 550 volts are applied in succession for 7- and for 52-second periods respectively, and each repeated once[1]—since we know the resistance of the body to be about 200 ohms in these circumstances[2] we can estimate that the heat liberated during this electrocution must be

$$\left[\left(\frac{2300}{200}\right)^2 \times 200 \times 14 + \left(\frac{550}{200}\right)^2 \times 200 \times 104\right] \times 0{\cdot}239 \text{ calories.}$$

This will be sufficient to raise the temperature of the whole body of a man of 10 st. through

$$\frac{0{\cdot}239 \times 200 \times (12^2 \times 14 + 8 \times 104)}{140 + 454} \text{ degrees centigrade}$$

or 3½ degrees Fahrenheit.

Since the conductivity of the cerebro-spinal fluid is about 150×10^{-4} (Eckel[3]), of the blood is about 120×10^{-4} (Strohl[4]), and of the other tissues of the body so much less than either of these, it is probable, as Langworthy and Kouwenhoven have stated,[2] that most of the current goes through the blood-vessels—but also much through the cerebro-spinal fluid which, although less in volume and more confined in extent, has the lower resistance. If we take the total cerebro-spinal fluid volume to be about 150 c.cm. and the total blood volume to be about 4 litres, and assume that the specific gravity and the specific heat of both these fluids is about unity, then we see that the above amount of heat—if confined to these tissues in which the current mainly passes—will be sufficient to raise their temperature through

$$\frac{0{\cdot}239 \times 200 \times 2848}{4150} \text{ C.°—i.e., through } 60° \text{ F.}$$

Now we know that in cases of legal electrocution temperatures of 145° F. have been measured in the cerebro-spinal fluid several hours after death[5]—i.e., a rise of presumably about 145–98° or 47° F. Therefore this rise in temperature can be well accounted for by the quantity and form of electricity used : it is sufficient most seriously to damage the central nervous system, but, as will be seen later, it is not capable of producing the lesions here in question.

When we attempt a similar calculation in cases of lightning stroke we are reduced to defining the probable upper limits of heating, since we have no precise data such as are available in the case of legal electrocution.

The total electrical energy in most lightning flashes varies from 5 to 50 coulombs [9] and 20 coulombs may be taken as a reasonable average.[10] If this quantity of electricity were passed entirely through the body, then, since the average head-to-foot resistance of this, in the absence of special electrodes and with a normal condition of the skin, is about 5750 ohms,[6] the heat evolved will be not more than

$$20^2 \times 5750 \times 0{\cdot}239 \text{ calories.}$$

This will be sufficient to raise the temperature of the whole of the body of a man of 10 st. through

$$\frac{20^2 \times 5750 \times 0{\cdot}239 \times 9}{140 \times 454 \times 5} \text{ F.°—i.e., through 14° F.}$$

The actual rise of temperature along the path of the current is much higher than this—as is shown by the linear burning of the skin. It is to be presumed that the amount of the total current which passes actually through, and not along the surface of, the body produces heating locally in its path, and the same considerations that were discussed above in relation to legal electrocution will hold here also. But as we have in this case no idea whatever of the amount of current passing through the body we cannot again in the same way estimate the probable amount of heating of the blood and cerebro-spinal fluid.

Yet even if we assumed that in the case of lightning stroke also there was a great local rise of temperature within the blood and cerebro-spinal fluid spaces—in neither of these cases could the observed lesions be explained in this way.

The coefficient of expansion by heat of the tissues of the body is relatively small. Liquids expand more than do solids, yet if we assumed that all the cerebro-spinal fluid in the nervous system were raised to boiling point its total volume of, say, 150 c.cm. would be increased between 37° and 100° C. only to 150 × 1·0042—i.e., to 150·6 c.cm.—a total increase of volume of about 0·5 c.cm. This certainly cannot cause any wide dilatation of the subarachnoid spaces, and the only possible way in which heat expansion alone can give rise to these changes is by actually boiling the blood and the cerebro-spinal fluid so that steam is given off under pressure sufficient to distend the tissues.

It is unlikely for two reasons that this does in fact take place. In the first place, the lesions in question are found in nearly all cases of fatal electrocution whether by lightning or by high-tension conductors and yet survivors from these accidents rarely have any permanent damage of their nervous system, so that it is most improbable that the degree of heating indicated above is ever approached. In the second place, the amount of heat available *in some cases in* which these lesions are found is not sufficient for this purpose.

Thus in the case of legal electrocution the 1200 coulombs of heat available is sufficient to raise the *blood and cerebro-spinal fluid through about 30° C.*, as has been shown above; it is not sufficient to raise it *anywhere near* to boiling point which would require 4150–63, or about 260,000 coulombs. Moreover the blood remains fluid and therefore cannot have been heated anywhere near to boiling point.

Therefore heating alone cannot account for the lesions observed and cannot make any serious contribution—by producing local expansion of the tissues—to their formation, although by causing coagulation of the tissues around the blood-vessels it may alter them in a way which leads to subsequent shrinkage during fixation.

ELECTROLYTIC EFFECT OF THE CURRENT

It has been suggested by Spitzka and Radasch [7] and quoted by others [8] that the dilated spaces and tear in the nervous system may be produced by the expansion of gases liberated by electrolysis from the tissue fluids. When a current is passed continuously in one direction through a conducting fluid which is an electrolyte, gases may be liberated at the places of entry and of exit of the current; they will not be liberated at intermediate places in the fluid.

Thus, in the first place the production of these changes in the nervous system by an *alternating* current is not accounted for, and in the second place no multiple, local, gaseous collections will occur. If the physical quantities involved are taken into account, this explanation is seen to be still less adequate, even for any case to which it might be otherwise applicable.

Since the electrochemical equivalent of oxygen is 0·00008293—i.e., this weight of oxygen is liberated by *1 coulomb of electricity—it follows* that the whole of the electric energy in an average lightning flash of 20 *coulombs* [9] will produce *only* 8293 × *20* × *10*—^{8} grammes of oxygen which will occupy at the normal body temperature

$$\frac{22{\cdot}4 \times 8293 \times 20 \times 10^{-8} \times 310}{32 \times 273} \text{ litres or about 1 c.cm.}$$

At the same time 2 c.cm. of hydrogen will be liberated so that the whole of the lightning flash if it all passed entirely through the electrolytes of the body would produce only 3 c.cm. of gas, an amount which cannot make any serious contribution to the production of the lesions in question.

MECHANICAL EFFECT OF THE CURRENT

Hassin [1] has examined the explanations given in terms of heating and of electrolysis and has rejected them on purely circumstantial grounds—i.e., on the absence of similar changes in cases of fatal hyperthermia and of caisson disease.[1] He considers that the changes are "due to purely mechanical factors. The action of a strong electric current is equivalent to direct mechanical injury . . . a momentary violent jarring . . . the mechanical factor—the jarring—is the electric current." [1]

That Hassin is right in his opinion that heating and electrolytic effects *alone cannot account* for these lesions follows from the calculations that have here just been *made*, but the *meaningless* expressions quoted above do not provide any reasonable alternative: to state that "the mechanical factor . . *is* the electric current" (see above) has no meaning; in fact, the mechanical factor is not even *due to* the *current*. The only mechanical effects that attend the presence of neighbouring electric currents are due to the electromagnetic forces; these are entirely negligible in the case of currents passing through the body and, such as they are, they will tend to produce contraction and approximation of the conductors along which they pass and not dilatation.

From the above it follows that none of the effects of a current passing through the body can account for the peculiar disruptive lesions in the central nervous system and an alternative explanation is needed.

It should be noted that explanations have hitherto been advanced only in terms of the electric *current* set up by the passage of a *quantity of electricity* through the body. No attention has been paid to the forces due to the presence of this electric *charge* upon the body. These will now be considered.

ELECTROSTATIC EFFECTS OF LIGHTNING AND HIGH-TENSION SHOCKS

It is in no case simple to decide what is the electrical state of affairs present when a man is electrocuted either by lightning stroke or by coming accidentally into contact with a conductor at high potential. The path of the current through the body can only be guessed at from a knowledge of the physical factors involved, and our knowledge even of the quantity and of the form of the electric energy supplied is in most cases uncertain. In the case of legal electrocution we know most about these factors, for we know the effective voltage, the resistance of the body, and the duration of the current. In the case of lightning stroke we know least—even the accepted physical views of just what is happening in the occurrence of a lightning flash have been profoundly modified [10 11] twice in the last five years.

An uncharged conducting body which is brought into electrical contact with a charged conductor becomes itself charged and will remain at the same potential as the originally charged conductor so long as the contact is maintained. If now the conducting body which has been charged in this way be removed from the originally charged conductor and come into contact with yet another conductor at a lower potential it will share its acquired charge with the latter—e.g., if it be earthed, the acquired charge will all run to earth and the final potential will be that of the earth. But should this happen while contact with the originally charged conductor is maintained the conducting body which received the charge will continue to do so, and a current will flow through it to the earth.

Thus if a man make effective contact with a conductor at high potential or if he be struck by lightning he will become suddenly highly charged with electricity, but a current will pass through him only if he is in a position to lose this charge in some way. The surrounding air will take away a little gradually,[10] most rapidly from angles and promontories of his person, but without setting up any current within him. If, however, he is making effective contact with the ground or with some conductor at low potential at the moment of the accident then the rate at which the charge passes through or over him will depend upon how good this contact is. If it is good, then the charge will pass away from him as rapidly as it is received, the current through or over him will be large and no charge will accumulate upon him. If it is poor, then the current will be smaller and the average charge maintained upon him will be proportionately greater. As a result of the current passing through him the heating, electrolytic, and mechanical effects discussed above may be anticipated. As the result of the charge upon him his body will become subject to certain forces which will be discussed in detail later and which are known as the electrostatic forces.

In the case of lightning stroke this distribution of current and of electrostatic effects will depend upon the degree of insulation of the man from the earth. If he makes good contact with wet ground through damp boots, then the current will be great and the effects of the static charge slight. If he makes poor contact with dry ground through boots that are thick and free from many nails, then more charge will accumulate upon him and for a longer period, and the electrostatic forces will be strong. That these differences in the effect according to differences in contact with the ground are not merely a matter of theoretical conjecture, but also of observed happenings, is to be seen from the eye-witness accounts that Spencer has recently published from his own personal observations.[12] He has pointed out that persons standing on wet soil when struck by lightning may fall to the ground in pain from powerful contraction of their muscles and yet have no memory of having received any blow and have no bursting apart of their clothing.

Langworthy and Kouwenhoven have shown that when a strong current is passed through the body of an animal the whole musculature becomes violently contracted, usually in tetany with an alternating current and in clonic jerkings with a direct current.[2] Another account of Spencer's illustrates the opposite effect: in circumstances of poor conduction to the ground inside a dry shelter the charge may accumulate upon the body with sufficient tension to escape from a flexed elbow on to another person standing nearby who is killed by receiving it.[12]

The electrostatic forces upon a charged body are derived from the mechanical repulsion which is exerted between all similarly charged particles or bodies. In the first place a charged body will be repelled from all similarly charged bodies with a force that depends only upon the amount of these charges and the distance between them. In the second place all those separate, constituent parts of the body which carry the charge will be repelled from one another.

Let us examine first the part that these forces may be expected to play in bringing about the effects of electrocution upon the body as a whole, and later the contribution that they may be expected to make to the production of the lesions inside the body.

The immediate effects, as seen by bystanders, of coming into contact with a conductor at high potential or of lightning stroke vary in different circumstances. In many cases, in which a man actually grasps a high-voltage conductor, he is sufficiently well earthed for the current through him to be initially strong, and the tetanic contraction of his arm muscles produced by this current causes him to remain clasping the charged object. In other cases widespread spasm of his whole musculature jerks him in some direction which may be either away from or towards the source of the shock. In some cases, in which two men standing near together are holding a conductor that suddenly becomes highly charged, they may be flung violently several yards apart—an instance of this repulsion is cited by Pearl.[13]

The immediate effects of lightning stroke are fairly well known: the following analysis of these effects is based upon the detailed accounts that have recently been given by Spencer of many such accidents that he has personally observed.

From these accounts we learn that when a man is struck by lightning he falls or is flung to the ground. He may afterwards remember having felt as though he received a stunning blow to the head. He is found to have a circumscribed effusion into the scalp over the top of his head. His skin is burnt both with characteristic linear brush-burns, over which the clothing is completely burst through, and also more severely beneath any metallic object carried about the person. These results are found in most cases of lightning stroke and are independent of the circumstances in which the man may be placed at the moment, but the circumstances provide other additional results of a similar nature.

Thus anything that the person struck may be holding is flung away; a bundle carried is burst open and its contents scattered[12] (p. 34); a baby held in its mother's arms is flung violently away with sufficient force to knock over another person sitting a few yards off (p. 41).

If the person struck is standing on or walking over open, flat country he falls directly to the ground (p. 43). If he is standing near to other objects that also are struck he will be flung away from them; when a group of men are struck while standing close together they are flung apart in different directions (p. 38); when a man is struck while standing close to some rigidly fixed conductor such as a tree or a tent pole (p. 72) he is flung directly away from this.

These effects have been explained in many different ways. The tetanic contraction of the muscles can account for the sudden "crumpling-up" of the man and his fall to the ground; it certainly could not jerk him through 9 or 12 yards or cause the other "repulsion" effects above described.

All these violent mechanical effects were originally ascribed haphazard and uncritically to "electricity." Recognising the need for some more scientific explanation, Sir Oliver Lodge ascribed them to violent commotion of the air around the path of the lightning flash, due to highly compressed air pushed before the current. As an alternative, others have suggested that the sudden air commotion may be due to heating and expansion. Examination of the actual happenings in cases of lightning stroke shows that neither of these explanations is valid. It has been pointed out that there is nearly always an effusion beneath the scalp of the person struck; this suggests that a heavy blow has been received but it can in fact always be distinguished from the effects of such a blow by the complete absence of superficial abrasions (ibid., p. 31). Violent commotion of the air sufficient to fling a man 12 yards away would certainly displace other movable objects in the immediate neighbourhood, but it is found that only persons and objects which actually share in the discharge are displaced in this way. There are many examples in Spencer's book of a full lightning flash passing to earth without displacing an object standing a few feet away when this object does not become charged (p. 72), and others which show that so little commotion of the air itself may occur that sleepers in a tent, down the pole of which the lightning strikes, may sleep on undisturbed (p. 83).

It is doubtful if expansion of the air by heating can, as is popularly supposed, account for the stripping off of the clothing. Although the clothes are burnt through with the heat this is only along linear burns, and since the air is a very poor conductor of heat this intense local heating will not have much effect in expanding any but the immediately adjacent air; the skin elsewhere on the body is conspicuously free from signs of heating and yet the clothes may be completely stripped off, leather belts and boots burst and discarded in a way that suggests that they have been repelled from the body in all directions.

The sudden violent displacement from one another only of those persons or objects that are struck must be due to the appearance of mutually repulsive forces between them that depend upon the reception of the electric charge. These forces may, in quite ordinary circumstances, be very great.

Thus we may examine the conditions when a man is standing in the shelter of a tree when both are struck by lightning. If we assume that the total discharge is 20 coulombs[9] and that only one-hundredth part of this reaches the man, the rest passing to the tree, that the man is standing 3 metres away from the tree and that only one-tenth of the charge on the tree is effective as being near enough to the man, then we find that he will be repelled from the tree with a force of

$$\frac{\frac{1}{100}\text{k} \times \frac{99}{1000}\text{k}}{300^2} \text{ dynes, where k} = 20 \text{ coulombs}$$

$$= 20 \times 3 \times 10^9 \text{ electrostatic units}$$

this is a force of

$$\frac{400 \times 9 \times 10^{18}}{9 \times 10^7} \text{ or } \underline{4 \times 10^{13} \text{ dynes.}}$$

This force acting upon a man of 10 st., as an impulse, will give him a velocity "V" away from the tree where "V" is given by

$$\begin{aligned} \tfrac{1}{2} \times 140 \times 452 \times V^2 &= 4 \times 10^{13} \\ \text{or } V^2 &= \frac{8 \times 10^{13}}{140 \times 454} \\ &= 1{\cdot}2 \times 10^9 \\ \text{i.e., } V &= 3{\cdot}5 \times 10^4 \text{ cm. per second or} \\ &\quad 35 \text{ metres per second.} \end{aligned}$$

If the man is standing erect when he is flung away with this velocity, and if he is 5 ft. 9 in. tall so that his centre of gravity is about 3 ft. from the ground, he will take a time "T" in falling freely to the ground where "T" is given by

$$3 = \tfrac{1}{2} \times 32 \times T^2, \text{ i.e., } T^2 = \frac{6}{32},$$

then he will be flung on to the ground a distance "D" away from where he was standing, where "D" is given by

$$\begin{aligned} D &= 35 \times T \text{ metres.} \\ &= 14 \text{ metres, or } 17 \text{ yards.} \end{aligned}$$

The chief assumptions used in making this estimation were that the man receives one-hundredth part of the discharge, and that one-tenth of the remainder on the tree is on a part that is near enough to be effective. Both of these assumptions are within reason, and the displacement of a man in these circumstances through 9 to 12 yards by these forces can be reasonably explained.

SURFACE CHARGE IN LIGHTNING STROKE

These forces of mutual repulsion between neighbouring objects will affect the central nervous system only in so far as they may damage the body by flinging it to the ground—i.e., in the same way as would any heavy fall. It is the second set of electrostatic forces that are capable of producing specific changes inside the body.

When a conductor becomes charged by a static electric charge, this charge is all concentrated upon its surface; directly contact is made in some one place between this body and another such as the earth, this charge will all run to earth along the surface or through the body of the conductor by whatever paths offer the best conductivity. So long as any charge remains upon the surface of the body it will produce a force acting outwards upon that surface, because each element of the surface is repelled from all other elements and the total effect is that the whole surface tends to expand away from the body in all directions. If the body itself is easily distensible it will expand—e.g., a soap-bubble when charged increases visibly in size. If the body is more rigid and its parts have strong cohesion no such visible expansion will occur, but the tendency to dilate will be exactly the same; the distending or expanding forces on the surface will have the same effect as a proportionate sudden reduction in the atmospheric pressure acting upon the body.

In the case of a man of average size who receives—to make the same assumption as previously—only one-hundredth part of an average lightning discharge, the force acting outwards all over him will be

$$2\pi\left(\frac{\Sigma}{A}\right)^2 \quad \begin{array}{l}\Sigma \text{ being the total charge, and} \\ A \text{ being the total surface area}\end{array}$$

this is

$$2\pi \times \frac{3 \times 10^9}{5 \times 1{\cdot}7 \times 10^4} \text{ dynes—i.e., } 73 \times 10^8 \text{ dynes}$$

this is

$$\frac{73 \times 10^8}{1{\cdot}5 \times 10^4} \text{ dynes/cm}^2.$$

or about half an atmosphere pressure

so that the effect of this charge will be equivalent to a sudden reduction of the atmospheric pressure to half its value.

This sudden expansile force will be communicated to all the tissues within the body, passing inwards as a wave of decompression, and these tissues will yield in proportion to their rigidity and cohesion, the distortion of all spaces within soft structures and the separation of parts having little cohesion is to be expected.

DISTRIBUTION OF THE LESIONS IN THE NERVOUS SYSTEM

The characteristic histological changes within the nervous system have been summed up by Spitzka and Radasch[7] as indicating that the tissues have been subjected to "some diffusely explosive or disruptive force." Langworthy and Kouwenhoven have described the changes in the cells of the nervous system of electrocuted animals as giving the appearance of "explosive suddenness," "almost as if the cell had been blown to pieces by dynamite."[2] The histological changes that follow a severe blow to the head do not include the peculiar changes that are here described. The localised gaps and tears and widening of perivascular spaces are due either to disruptive forces originating locally, or to the sudden local yielding of the tissues in many places to some general expansile force.

It is difficult in any given case to say what particular combination of the electrothermal, the electrolytic, and the electrostatic effects is responsible for a given lesion in the brain. It is more easy to explain why the lesions which are in fact found, are present in the particular situations in which they do occur.

It has been seen that the electrostatic effects will produce the greatest changes in the nervous system in those places where rigidity is smallest and cohesion least. This suggests that their maximal effect will be upon the fluid spaces rather than upon the brain substance and, in respect of the fluid spaces, greater in the subarachnoid space and its smaller ramifications which do not possess special sheaths than in the blood spaces, which are surrounded by elastic and muscular walls.

The heating and the possible electrolytic effects will be greatest both outside and inside the body where the electrical conductivity is highest. Outside the body this is along creases in the skin where sweat has collected[12] and over metallic objects to which the charge has been attracted. In the central nervous system as a whole, electrical conductivity is best in the cerebro-spinal fluid,[3] not quite so good in the blood,[4] and very much smaller in the brain substance.[2] The current effects of heating should therefore be greatest in the cerebro-spinal fluid spaces and next in the blood-vessels. In respect of current passing through the substance of the brain itself, it is interesting to note that from their electrical experiments on animals Langworthy and Kouwenhoven have found that the Purkinjé cells suffer an exceptionally severe amount of damage,[2] while Hassin has found that the tearing apart of adjacent cortical layers in man is particularly conspicuous between the damaged Purkinjé cell layer and the granular layer in the cerebellum.[1]

The proportion in which the causation of these lesions in the central nervous system peculiar to fatal electrocution is to be ascribed to *current* and to *electrostatic* effects can only be decided when we have a more accurate idea of the electrical state of affairs within the body than we have at present. The observed distribution of these lesions seems to correspond closely with what is to be expected from a theoretical consideration of the known possibilities.

SUMMARY

Reasons have been given for believing that the heating and electrolytic effects of high-tension currents cannot be held responsible for the production of those lesions in the central nervous system which are peculiar to fatal electrocution and to lightning stroke. The contribution of electrostatic forces to the production of these lesions is discussed.

TREATMENT WITH THE CARBON DIOXIDE SNOW PENCIL

By Henry C. Semon, M.D. Oxon., M.R.C.P. Lond.
PHYSICIAN TO THE SKIN DEPARTMENTS, ROYAL NORTHERN AND HAMPSTEAD GENERAL HOSPITALS

THE chief difference between the destructive action of the hot cautery or the cold cautery (diathermy) and CO_2 treatment may be summarised in two words: vital reaction. You cannot destroy a tumour or a vascular nævus on a cadaver by freezing it, although obviously you can burn it away. Vital reactions are never immediate to the naked eye. Even the weal of the stinging nettle or t[illegible]e whip lash takes an appreciable time to develop; [illegible]s *also* a vital reaction and cannot be produced af[illegible] *death*. These points are fundamental, and import[illegible]f the mechanism of CO_2 treatment is to be [illegible]*stood*. The effects are the result of damage t[illegible] *delicate* endothelial walls of blood-vessels, [illegible]*sequent* exudation of serum (causing a b[illegible] *develop* locally), and ultimately a reduc[illegible]e *blood*-supply to the area frozen. This k[illegible]*al necrosis* to an extent depending on two factors: (1) the length of time during which the pencil was in contact with the tissue; and (2) the pressure with which it was applied, and the counter-pressure of firm underlying tissue. More pressure can be used on bone, for example, than on the eyeball behind the eyelids, from which no counter-pressure can be easily elicited.

It seems to follow that the more vascular a tumour the more vulnerable it should be to the effects of freezing. Within limits this is true, but it must be remembered that blood—free blood as in a large cavernous angioma—is a bad conductor of heat (and, therefore, of cold); and that it is by no means always possible to empty the tumour of its blood before it is frozen. Moreover, a cavernous angioma is deficient in normal endothelium, and in the sympathetic connexions that are responsible for the vital reactions producing exudation and subsequent necrosis. Fibrous tissue contains relatively little vascular tissue, and it is doubtless for that reason that freezing will have little effect on a fibroma or lipoma or even on a wart unless the pencil overlaps the tumour and is able to provoke a reaction in the normal tissue in the vicinity. With cellular structures, especially if they are soft in consistence, the position is different, for these, if they contain a moderately good blood-supply, will respond to application of the pencil.

If these principles are correct, it follows that the acetone snow mixture recommended by some authors is less efficient than the pencil, for the factor of pressure is lacking, and moreover the temperature of such a mixture depends largely on atmospheric conditions and the relative amounts of snow and solvent used. It is, in fact, far less efficient, and I do not recommend it for dermatological purposes.

The vital reaction may be the chief reason for the extreme rareness of septic complications after freezing, and probably also explains the relative perfection of the resulting cicatrices, which are never hypertrophic or keloidal. Secondary contraction and resulting deformity or interference with function (of an eyelid, for example) are equally rare, and afford additional reasons for the use of this, one of our least dangerous and most efficient therapeutic weapons.

The number of conditions, both dermatological and other, that can be treated by CO_2 is very great, and a glance at the list submitted by Lortat-Jacob and G. Solente in their excellent text-book[1] suggests that there is scarcely a dermatological condition which at some stage in its evolution is not amenable to cryotherapy. The list includes acne vulgaris and rosacea, keloid, angioma, angiolupoid, aphthæ, and so on, right through the alphabet to xanthelasma and xeroderma pigmentosum. Among non-cutaneous affections, trachoma and chronic cervicitis are cited as being favourably influenced. With a little practice, and keeping in mind the dictum that it is always easy to repeat a treatment but not so easy to remove the effects of an overdose, the practitioner runs no risk of doing harm to any chronic and circumscribed condition which in his opinion would be benefited by the reaction consequent on freezing, whether he aims at producing a mild serous exudation only or a destructive or necrotic effect.*

TREATMENT OF STRAWBERRY NÆVI

As an illustration of the value and use of the method, I propose to describe its application to the condition most commonly calling for such treatment—namely, the raised, localised strawberry nævus, or angioma circumscriptum.

The patient is usually an infant, and there is no contra-indication to the application of the pencil provided the child is in normal health and not suffering from an infective skin condition. The snow is pressed into a circular receptacle or mould slightly larger than the nævus to be treated, and is then expelled by means of the piston which hammered it into shape, and wrapped in cotton-wool in such a way that about a quarter of an inch protrudes beyond the wrapping. The patient is firmly held, preferably by a nurse, and the pencil applied with a pressure of about 1 lb. weight for 10 to 15 seconds, depending on the approximate thickness of the nævus. Great care should be taken to see that overlapping is complete and, as far as possible, equidistant around the circumference. The tissues turn white and are depressed below the surface for about the same time or a little longer than was required to freeze them. Thawing soon takes place and the circulation returns. This stage is the most painful of the whole procedure, but lasts no longer than about three minutes.

Depression of the frozen surface gives place to slight elevation, and very soon a ring of exudation, considerably wider than the frozen area, makes its appearance. This may or may not progress to the formation of a bulla, which should not be immediately pricked, as it will almost certainly refill with serum. If still present some five or six hours after the operation, the fluid may be let out with a sterile needle and the small reacting area liberally sprinkled with boracic and starch powder, or calamine lotion containing a little spirit. Ointments should not be applied at this stage at all, and the greatest care should be taken to preserve the roof of the bulla, which eventually forms a firm crust and is nature's own dressing. It must not be removed under any pretext, or an indolent rapidly crusting and slightly ulcerated area will be left and the eventual scar may be unsightly or hypertrophic. The crust separates spontaneously in about ten days as a rule, and it will then be apparent to what extent the vascular tissue of the nævus has been destroyed. Residual hyperæmia must not be mistakenly regarded as angiomatous, and in any case the immediate temptation to repeat the freezing should be resisted, for another week or two, unless the original tumour was of too large a size or irregular a shape to be covered by the circumference of the pencil chosen.

In this connexion the problem sometimes arises how best to deal with some of the peculiar and grotesque shapes that are met with in practice. Patterns may be cut, after tracing out an approximate and rather larger outline of the nævus, *on oiled paper*. This is laid upon a sheet of cardboard or any other non-conductor, and the approximate shape of the nævus cut out; the cardboard frame is then placed round the nævus, interposed between the skin and the larger-sized freezing pencil, as a more or less accurate shield against freezing of normal tissue. Or, again, the area may be frozen in sections. If this is done great care must be taken *to select each of them at sufficient distance* apart to prevent overlapping and consequent double dosage.

---

[1] La Cryothérapie. Paris, 1930.

As regards apparatus, a large cylinder (and spare) is an
al for hospital requirements, but for private and occasional
re is a good little pocket apparatus put up by the
Co. The dwarf cylinders are large enough to provide
w for the average case, and the cost of renewals is

OTHER USES OF THE METHOD

Early rodent ulcer is another condition for which the pencil may be used, except when it occurs on the eyelid where counter-pressure from bone is not available. In such cases radium is to be preferred. On the forehead or nose CO_2 will give results as good as radium. Sepsis should be first controlled by lotions or ointments, and crusts must be removed before the snow is applied. A minimum exposure for a rodent ulcer is one minute; firm pressure should be used and care taken to ensure that the pencil overlaps the tumour at every point of its circumference. It goes without saying that the treatment should only be used in cases which have not involved the underlying bone, and in which the infiltration is confined to the skin.

For the common wart the actual cautery is preferable, mainly because the papillomatous processes are too deeply situated for effective refrigeration; the flat seborrhœic and senile varieties of wart, however, are rapidly eliminated by snow treatment. Applications with moderate pressure vary from 20–30 seconds, and can be repeated as required. Some forms of keloidal tissue can also be treated in this way, but are best submitted to X ray or radium exposures by an expert. Soft papillomata of various types are also suitable for CO_2 treatment provided their substance is not too fibrous. Conditions other than dermatological in the mouth, rectum, and vagina, and even on the conjunctiva, have been treated by cryotherapy with excellent results.

Clinical and Laboratory Notes

A CASE OF PHLEGMONOUS GASTRITIS

By J. G. Jamieson Coghill, M.B. Aberd.
HON. SURGEON TO THE LEIGH INFIRMARY, LEIGH, LANCS

Miss A. B., aged 41, a clerk, was taken home from work at 11 A.M. on Jan. 18th on account of abdominal pain and vomiting. At 9 P.M. on the same day I saw her for the first time; there was a history of incessant vomiting and considerable upper abdominal pain. The vomiting had come on suddenly that same morning, but she had complained of a little nausea and malaise for a few days before.

Examination revealed considerable tenderness in the epigastrium; there was somewhat indefinite rigidity in the midline between the xyphoid and the umbilicus; she was able to sit up in bed of her own accord and without assistance, and contraction of the recti muscles did not cause her any pain or indeed any apparent discomfort. The axillary temperature was 104·2°, with pulse-rate 100 and respiration-rate 24; the bases of both lungs were clear.

On the morning of the 19th she was removed to Leigh Infirmary because the pulse-rate had gone up to 110. No satisfactory diagnosis could be arrived at as the signs and symptoms were extremely conflicting; the temperature remained in the neighbourhood of 104° with occasional remissions to 101° for an hour or two at a time. The respiration-rate did not rise above 28, and there were no signs of basal or diaphragmatic pneumonia. The pulse-rate went up steadily to 120; tenderness and rigidity quickly became more marked and it was clear that an acute upper abdominal catastrophe had occurred. Gall-bladder, pancreas, and duodenum did not appear to be the origin of the trouble; the most likely lesion to be encountered was considered to be a perigastric abscess with some leakage into the general peritoneal cavity.

I opened the abdomen by a right upper paramedian incision; clear free fluid welled up through the opening in the peritoneum and a large soft red tumour presented itself against the parietal peritoneum; this was the stomach, the peritoneal coat of which was much injected, the walls thick and doughy and of even consistence throughout; the swelling and thickening of the stomach ceased abruptly at the pylorus and all the organs in the upper abdomen, other than the stomach, appeared to be perfectly normal. I made a small incision through the peritoneal, muscular, and submucous coats as far as the mucosa itself; there was gross thickening of all coats, and the submucous coat appeared as a yellowish-white layer—in consistence and appearance very much like cream cheese; on squeezing the stomach wall gently, multiple beads of pus exuded from the submucous coat. A drainage-tube was inserted at the site of incision and also a large suprapubic drain. Death occurred on Jan. 22nd from general peritonitis.

Three hours after death I removed the stomach in toto; uniformly thickened, it was deeply congested on the peritoneal surface from the cardiac orifice to the pylorus. Macroscopically the submucous coat was much in evidence as a yellowish cheesy layer from which pus could be expressed with little difficulty; the mucous membrane was much injected and ecchymosed, more particularly in the pyloric antrum. There was no sign of ulceration anywhere on the mucosa itself, nor was there anything to indicate any trauma which might have been the origin of this extremely grave condition.

To Dr. W. E. Cooke, of Wigan Infirmary, I am indebted for the following histological and cultural report. "Histological examination shows purulent infiltration of all the coats. Cultures give a mixture of *B. coli* and streptococci."

The extreme rarity of this condition, together with the difficulty of diagnosis and the utterly hopeless outlook as far as treatment, either surgical or medical, is concerned, make it worthy of record as followed from the origin of the illness to the post-mortem findings.

ACUTE HÆMOLYTIC ANÆMIA

By H. A. Dunlop, M.D., M.R.C.P. Lond.
PHYSICIAN TO THE METROPOLITAN HOSPITAL, LONDON; AND
A. G. Sanders, M.B. Lond.
LATE SENIOR RESIDENT AT THE HOSPITAL

A boy, aged two years and three months, was admitted to the Metropolitan Hospital on August 31st, 1932.

The mother had noticed that on the previous day the child's urine had become dark. The bowels were costive, but the child was said by the mother to be well in himself and "not moody or ill at all." The urine was definitely stated to have always been normal until the day before admission. The child had been taking no medicine. On closer questioning the mother said that the child had had "a bit of a cold for the last week" and that although he had always been rather a pale child, the parents had for the last week "noticed a yellow look about him."

Condition on examination.—Skin and mucosæ pale. Conjunctivæ yellow. Fat child. Tongue moderately furred. Tonsils ragged. Teeth good. Heart not enlarged. Systolic murmur at pulmonary area. Lungs: nil abnormal discovered. Abdomen: spleen palpable. Nervous system: no abnormal signs. The urine was very dark and gave a strongly positive guaiacum reaction, but was free from red corpuscles. Although a spectroscopic test was not performed, there can be no doubt that hæmoglobinuria—or more probably methæmoglobinuria—was present.

Course of illness.—The temperature chart showed an irregular pyrexia, varying from subnormal to 101° F. The blood count showed on Sept. 2nd:—

Red cells	1,700,000	Polymorphs ..	55%
White cells ..	28,000	Lymphocytes ..	38%
Hæmoglobin ..	28%	Monocytes ..	7%
Colour-index ..	0·82	Eosinophils ..	0

The red cells showed slight anisocytosis and polychromasia and eight nucleated forms were seen in bed-making.—Dr. H. **Trayer** had found that felsol powder gave relief in dyspnœa. For failing appetite, half a pint of hot water sipped half an hour before dinner was helpful. Brandy, sherry, or port could sometimes be allowed with advantage.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

A meeting of this association was held at B.M.A. House on May 22nd, when Dr. **Lucy Wills** spoke on

Tropical Macrocytic Anæmia

Dr. Wills gave an account of her work on this subject during the last five years. In 1928 this condition was described in pregnant women under the title "pernicious anæmia of pregnancy" and was a serious cause of maternal and fœtal mortality in the large cities of India. The blood picture resembled that of true pernicious anæmia, but the condition could be distinguished from idiopathic pernicious anæmia by the following characteristics: (1) earlier age-incidence and the association with pregnancy; (2) absence of natural remissions except after delivery; (3) the presence of free hydrochloric acid in normal amounts in the gastric content of the majority of cases; (4) the absence of a raised indirect van den Bergh reaction or an increase in urinary urobilin; (5) absence of nervous involvement; (6) slight differences in the blood picture—e.g., less poikilocytosis and polychromasia, higher white cell counts. The cases were frequently febrile but no evidence could be obtained of an infective or toxic origin. The general course of the disease and the response to adequate doses of liver or liver extracts suggested a nutritional origin. Further study showed that an identical form of anæmia also occurred among men and non-pregnant women, which also supported the view that the disease was a deficiency state, the higher incidence and the greater severity in pregnant women being due to the added demands on the organism during pregnancy. A dietetic survey among the hospital classes in Bombay revealed a deplorable state of multiple deficiencies, with no significant difference in the diet of sufferers from this anæmia. All the diets were particularly low in vitamins A and C. Experiments with rats fed on diets based on those in common use among sufferers from this anæmia resulted in the production of a macrocytic anæmia, which, however, was associated with the multiplication of Bartonella organisms in the blood stream. A search for similar organisms in the patients gave negative results and large doses of vitamins A and C had no curative effect. Similar experiments with monkeys (Bartonella free) again led to the production of a macrocytic anæmia, but both in the control animals, who were receiving additional rations of vitamins A and C, and in the experimental animals. When the ration of the vitamin-B complex was increased by the addition of Marmite to the diet the anæmia disappeared rapidly. The trial of marmite in human cases was equally successful, 15–30 g. of marmite daily resulting in a maximal response and a rapid rise in the red cell count in both pregnant and non-pregnant cases. At this time Castle and his co-workers were publishing their work on the factors, intrinsic and extrinsic, necessary for the formation of the hæmopoietic factor in liver. As the tropical cases had apparently normal gastric secretion it was assumed that the intrinsic factor was present, but that the missing dietetic factor was Castle's extrinsic factor. After the publication by Dr. Wills of the results with marmite, the Boston workers tried a similar autolysed yeast extract and found that though inactive alone, when incubated with normal gastric juice it was highly active in the cure of idiopathic pernicious anæmia. These workers postulated vitamin B_2 or some factor closely associated with it as the extrinsic factor in pernicious anæmia.

At the same time Dr. Wills said further work with standardised vitamins and yeast preparation in relation to tropical macrocytic anæmia had already been started by her with the help of Miss H. Chick, D.Sc. For the test of these preparations uncomplicated cases under controlled conditions were used, and the activity of a preparation was judged by the height of the reticulocyte peak and the subsequent rate of blood regeneration. Vitamins B_1, B_2, and B_4 were inactive curatively when given in the purest available form —i.e., as acid clay and extract of egg white, or in watery yeast extract of known vitamin potency; further, preparations of marmite free from these vitamins were still active curatively. The vitamin-B complex was, therefore, excluded as the hæmopoietic factor in marmite curative in tropical macrocytic anæmia and also presumably as the extrinsic factor in pernicious anæmia. Further experiments showed that the hæmopoietic factor in marmite was heat stable and was neither precipitated nor inactivated by 80 per cent. alcohol. Whole yeast was inactive, but Dr. Wills suggested that this might be due to the fact that yeast cells are resistant to gastric digestion, rather than to the absence of the hæmopoietic factor.

She summed up the present position as follows: Tropical macrocytic anæmia is a deficiency, dyshæmopoietic anæmia due to the lack of the hæmopoietic factor in the liver known as the pernicious anæmia factor. The disease is distinct from idiopathic pernicious anæmia and is not necessarily associated with diarrhœa, defective gastric secretion, or pregnancy, other causes of macrocytic anæmia. The deficiency is, in her opinion, due to a dietetic lack in some substance present in marmite, which is not one of the known B-vitamins, but which is probably identical with the extrinsic factor described by Castle for idiopathic pernicious anæmia. The tropical anæmia is cured by the administration of the missing factor as marmite or of the pernicious anæmia factor present in liver.

Dr. **Helen Mackay** asked if there was any explanation of the absence of nervous symptoms and natural remissions and of the fact that there was no record of the disease in children, who were normally more susceptible to deficiency diseases than adults.

Dr. **Wills**, in reply, said that possibly as regards nerve changes there was not time enough for these to develop in the young patients, but it seemed more likely, in view of the age of some of the non-pregnant patients, that the nerve lesions of true pernicious anæmia were associated with the gastric lesion rather than with the absence of the hæmopoietic factor, which would explain the absence of nerve lesions in the tropical form. She thought that further study might show that remission did occur in exceptional cases, but had no explanation of the absence of recorded cases in children.

St. John's Hospital Dermatological Society.—The Prosser White oration of this society will be delivered by Dr. William Allen Pusey, of Chicago, on Wednesday, June 27th, at 5 P.M., at the house of the Royal Society of Medicine, 1, Wimpole-street, W. The title of Dr. Pusey's lecture will be "Disease, gadfly of the mind, especially the stimulus of disease in the development of the mind."

REVIEWS AND NOTICES OF BOOKS

Relief of Pain in Childbirth

By F. Neon Reynolds, M.C.O.G., F.R.C.S.E., Hon. Obstetric Surgeon to the Hospital for Women and Children, Harrow-road, and Southend General Hospital. London: Medical Publications Ltd. 1934. Pp. 114. 10*s.* 6*d.*

This book appears at an opportune moment, for the relief of pain in childbirth is now being much discussed both within and without the medical profession. Mr. Reynolds sets out the many drugs and methods advocated for the purpose and gives a judicial summing-up of their merits and demerits while clearly indicating his own preferences.

His chief objective he describes as the humane relief of pain, with consequent conservation of the strength and natural resistance of the patient. The ideal to be aimed at for the pains of the first stage is an analgesic or hypnotic that produces drowsiness, with sleep in a state of complete relaxation between uterine contractions. An inhalation anæsthetic is unsatisfactory in that it leaves the woman wakeful, awaiting with apprehension the next contraction, and making frantic efforts to inhale deeply and rapidly on the first warning of its onset. Anæsthesia deep enough to produce sleep as one pain passes off and to avoid rousing by the next involves long-continued soaking in the anæsthetic. In the expulsive stage, on the other hand, relief of pain during contractions with recovery to consciousness in the intervals is the aim, as thereby the assistance of the patient can be obtained by instruction between the pains. Hence an anæsthetic, rapidly induced and rapidly recovered from, such as nitrous oxide or chloroform, is best. As the moment of expulsion nears, the anæsthesia can be raised to the degree required to remove voluntary control, thus allowing the head to be born as and when the attendant desires; immediate cessation of further administration usually results in the delivery of the body and afterbirth by bearing-down efforts.

Drugs and methods suited to fulfil the requirements for each of these stages are fully discussed in the light of their simplicity, ease of administration, effectiveness, and after-effects on mother and fœtus. The barbiturates are dismissed as dangerous; avertin is said to have the disadvantages for routine use of variable results and of the necessity for calculating dosage and making-up the solution for each case. A rectal injection of paraldehyde in olive oil, with or without a single injection of morphine and scopolamine, is advocated because of its ease of administration, general applicability, effectiveness, and ready combination with other methods in the expulsive stage. For this later period either nitrous oxide with oxygen or chloroform is the stand-by; and the conditions favouring the use of one or the other are fully considered. The possibilities of relieving pain in the woman attended by a midwife only is discussed in an instructive chapter. Crushable capsules of chloroform are not favoured, but it is held that paraldehyde rectal injections which are usually given by the nurse or midwife when working under a doctor, if put up in containers of a single dose ready for use, could safely be left in the hands of the midwife alone and would be effective for all but the pains of the birth itself. For these, for which relief is most needed, some hints are given of what might be done by devising a form of apparatus of the Junker type, so sealed and regulated as to allow only the flow of a weak and intermittent supply of chloroform, sufficient for each pain. The author himself expresses doubt whether or no he is too optimistic in envisaging something of this kind; it is clear that in any case the method must be rendered foolproof and tested by extensive trials before being sanctioned.

The need for attention to minor troubles during pregnancy in order to obtain the confidence and coöperation of the patient is duly stressed; but no mention is made of the possibility of lessening pain and fatigue—and thus lessening the resort to drugs—by instruction of the expectant mother in the part she has to take during labour, by distracting her thoughts from fears and anxieties and by teaching her how to relax completely. Those blessed and most humane weapons, anæsthesia and the forceps, that have so much to their credit have also a debit side; for the pursuit of other means of securing easy and natural parturition has been hindered by the very fact of their ease of application and efficiency. But they should not prevent the methods, to which they are supplementary, from being tried first.

Dr. Reynolds has succeeded in the task he has set himself and his book should receive wide acceptance because of its eminently practical and judicious character. He expresses himself well and clearly, though the over-sensitive may shudder when told "to gently but firmly rub" or on finding that "forceps" is plural. He consistently spells the first syllable of scopolamine with an "a," but seems unable to make up his mind whether "primi-gravidæ" and "multiparas" should be hyphened or not or their plurals be Latin or English. There will doubtless soon be an opportunity of rubbing out these trifling blemishes. The printing is beautiful and adds much to the pleasure of reading the book.

Traité de physiologie, normale et pathologique

Tome V., Respiration. By G.-H. Roger, Honorary Professor of Physiology; and Léon Binet, Professor of Physiology in the Faculty of Medicine, Paris. Paris: Masson et Cie. 1934. Pp. 474. Fr.100.

Like its companion volumes, this book is made up of articles by various contributors. It opens with a short but valuable section on tissue respiration by Pierre Thomas, which might well have been lengthened at the expense of some less relevant and even redundant material which occurs later. The "considérations histophysiologiques" by Léon Binet which follow are instructive, drawing attention to properties other than respiratory possessed by the cells of the lung alveoli, and to the importance of the lymphoid tissue of the lung. Pulmonary ventilation is treated by the same author. This section seems rather scrappy owing to the number of subheadings such as cough, hiccough, types of respiration; the mechanics of the respiratory movements could have been developed more fully. One does not grudge the space devoted to consideration of the amount of lung tissue necessary to support life and the possibility of actual hypertrophy in the young; this is interesting and instructive, as are the pages dealing with the bronchi and pleura.

L. Dautrebande writes on gaseous exchanges in the lungs and tissues, giving perhaps a little too much space to methods and to the carotid sinus control of respiration, but finishing with an interesting section on physio-pathological conditions which includes the effects of acute and chronic affections, and a general treatment of oxygen-lack and the various factors which lead up to it. There is some repetition of this matter in the contributions of H. Hermann, C. Heymans, and L. Binet on basal metabolism, nervous control of respiration, and the physiopathology of some respiratory affections respectively. The section on nervous control is excellent, as was to be expected; basal metabolism, though it necessitates a knowledge of respiratory exchanges, and is here competently dealt with, might have been better placed than in the volume on respiration.

Apart from inevitable overlapping and discontinuity associated with a compilation of this sort—the editors have obviously refrained from any attempt to unify it—the articles themselves are good, and the footnote references which abound cover a wide and representative field. The book is generously illustrated with graphs, tracings, and pictures of apparatus (there is some repetition even here), and contains some very good histological colour plates.

Baths and Medicinal Waters of Britain and Europe

By Michael G. Foster, O.B.E., M.D. Camb., F.R.C.P. Lond. Bristol: John Wright and Sons, Ltd. 1933. Pp. vi. + 225. 12*s.* 6*d.*

The author of this book has peculiar qualifications for his task, since he worked during a long term of years on the Riviera and the Engadine in the winter and at a British spa in the summer months. He has thus been able to distinguish, as few others could do, the effects of a change of climate in a great variety of chronic illnesses from the effects of the systematic use of waters and baths. He points out that at some of the leading spas the course of treatment has "very rightly" developed into a specialty of the place. The results obtained at such spas depend as a rule upon a combination of methods, the result of much clinical adaptation, also on climate and other local characteristics. In Dr. Foster's view, however, the waters come first; some waters, for example, are held to be of definite value in vascular hypertension associated with metabolic disorders, and particular actions have been attached to sulphur waters and others to calcium and alkaline waters. Unfortunately in many spas little attention is paid to the differentiation of hydrological treatment. Another matter in which Dr. Foster's experience is welcome is in the treatment of the type of congestion of the liver met with in the tropics, which occurs even *in abstemious persons*. It is commonly supposed that a change to England is the main remedial agent, but Dr. Foster holds that the use of waters is of paramount importance. He believes also that gynæcological and cardiovascular cases and many chronic dermatoses could well be treated more specifically at the British spas. He is convinced that a large number of common chronic disorders yield to treatment at an appropriate and well-appointed spa more readily than to a mere change of climate.

In the many diseases known as rheumatic the popular name still "serenely over-rides" the transitory ætiological classifications. Rheumatic fever is only of interest to the hydrologist from the occasional value of cooling baths in hyperpyrexia. But in regard to chronic rheumatism the author wisely emphasises the thesis, too often forgotten, that the first aim of treatment should be to relieve pain. He advises a more extensive use of hot peat baths, in sciatica for example, because they remove the inhibitions of pain. When pain is allayed normal nutrition may return and adventitious deposits may be removed. A similar rule applies to rheumatoid arthritis, and baths furnish powerful means for reducing the "constant trauma" of pain. In osteo-arthritis he advocates brine baths and pools for improving the movement of the joints, and for feeble patients fango packs and local vapour baths.

Brief descriptions are given of the different kinds of waters and baths and their uses. The latter half of the book is occupied with a short survey of the principal British and European spas, founded on the work on "Climatotherapy and Balneotherapy" by Sir Hermann and Dr. Parkes Weber. To this Dr. Michael Foster has now added much new material, which makes the book a valuable and comprehensive guide in the choice of a spa.

Facies Dolorosa

Das schmerzensreiche Antlitz. By Dr. H. Killian. Leipzig: Georg Thieme. 1934. Pp. 88. M.19.60.

The title of this book does not adequately indicate its contents. It is really an attempt to illustrate the facies of disease, meaning by that not only the organic changes wrought in the face by illness but also the alterations of expression which result from the patient's mental reactions to his malady. The author presents upwards of 60 photographs illustrating different examples of disease which he arranges into nine groups under such titles as facies dolorosa, pale faces, goitres, cachexia, stupor and coma, and so forth. As he is himself a surgeon most of the pictures are naturally of surgical conditions. The artistic excellence and beauty of reproduction of the photographs deserve high praise, but the general effect of glancing through them is one of disappointment. Few of the different sorts of facies depicted are really "typical" of anything, for the fact is that not many diseases have a distinctive facies. The absence of colour also in a photograph interferes greatly with the display of some of the most characteristic changes effected by disease.

A Synopsis of Hygiene

By E. W. Caryl Thomas, M.D., B.Sc., D.P.H., Barrister-at-Law; Medical Officer of Health, Dagenham. Bristol: John Wright and Sons, Ltd. 1934. Pp. 283. 10*s.* 6*d.*

This book, intended for medical students, contains a large amount of information, most of it in summary form. The writer is modern in his outlook and, on the whole, accurate in his facts. The only part which is open to serious criticism is Chapter III., which deals with vital statistics. It is doubtful whether it is worth while trying to convey to medical students the significance of so many statistical terms, but if it is to be done those paragraphs which deal with estimates of the population according to a geometrical progression (not now, by the way, the "method of the Registrar-General"), with the calculation of a standardised death-rate, with the meaning commonly applied to the comparative mortality figure, and with the definition of the infant mortality-rate should be revised in any subsequent edition. For those who can absorb information in a concentrated form the book should be invaluable.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

IV.—THE CALIFORNIAN EXPERIENCE

AMERICAN experience of legal sterilisation ought to provide exact material for study. Sterilisation laws now exist in 26 States in the Union, and in four others—New York, New Jersey, Nevada, and North Carolina—similar laws have ceased to be operative. Up to Jan. 1st, 1933, a total of 16,066 operations had been performed under these laws, of which 8504, or 53 per cent., were done in California. During the calendar year 1933 a further 578 sterilisations were done in California, not including operation by private physicians on individuals at their own request. In the view of the Brock Committee no entirely independent review of the Californian results has been attempted, and they find it significant that the parole-rate in Californian institutions is equalled by the parole-rate in a large mental deficiency colony in a State which had no sterilisation law. The committee consider that, while there is no evidence of harm done by sterilisation, nothing practical has really been done either. The argument cuts both ways, however, for if it is agreed, as it should be, that sterilisation is not a substitute for institutional care where this is necessary, the limited parole-rate in California may simply indicate that this principle was being upheld.

The Californian statistics refer entirely to sterilisation of the insane and feeble-minded. These patients represent only a small proportion of the group for whom the Brock Committee recommend sterilisation as an appropriate measure, and it would be unfair to judge the merits or demerits of voluntary sterilisation solely in terms of its application to people suffering from mental disabilities.

THE INTENTION

Between 1927 and 1930, under the auspices of the Human Betterment Foundation, the available Californian evidence was published in the form of a series of papers to various medical and technical journals, and in 1930 these 26 papers were collected and published in book form.[1] In California the first sterilisation statute was adopted in 1909; a new law repealing the old one was enacted in 1913 and amended in 1917. The present law provides for the sterilisation, with or without consent, of "any person who has been lawfully committed to any State hospital for the insane or the Sonoma State Home, and who is afflicted with mental disease which may have been inherited and is likely to be transmitted to descendants, the various grades of feeble-mindedness, those suffering from perversion or marked departure from normal mentality or from disease of a syphilitic nature." These rather formidable provisions are modified in practice by the fact that the consent of the patient's relatives is always sought and usually gained before the operation is performed; not one operation in ten, we are told, is performed against the wishes of the relatives, and probably the proportion is really lower. The Act is complicated by penal and therapeutic provisions which might be expected to prejudice its success as a eugenic measure. For example, whenever in the opinion of prescribed officials sterilisation will be beneficial to the physical, mental, or moral condition of certain recidivists in the State prisons, who are also moral or sexual degenerates or perverts, they may order the operation; and the Californian penal code provides for the sterilisation as "additional punishment" of any person adjudged guilty of carnal abuse of a female under the age of 10. Parents might well refuse to consent to a measure which had such penal associations.

There has been a steady increase in voluntary sterilisation in the State, so that in practice this prejudice does not appear to tell very heavily against the success of the Act from the eugenic standpoint. For obvious reasons, however, the extent of such prejudice cannot be estimated, and it is impossible to judge whether it has interfered much with the ascertainment of cases. The element of compulsion in the Act, though used with discretion, may also tend to "drive defect underground," to use the phrase of the Brock Committee. Compulsion, as they pointed out, is likely to defeat itself, for if public opinion is favourable, compulsion is unnecessary, and if public opinion is indifferent, compulsion may convert indifference into hostility.

The aim of the Californian, as of other sterilisation laws, has been to protect the State from the propagation of defective or insane stock, and to stabilise those who, apart from the chance of reproducing their kind, are fitted to take part in community life. Most of the sterilising operations performed in California since the passing of the original Act have been upon insane people in the State mental hospitals; only about one-fifth have been performed on mentally defective patients. At the Sonoma State Home for mental defectives, however, it is now the rule that no patient shall leave the home, even for a short holiday, unless sterilised. In a paper published in 1927 Mr. Paul Popenoe, the very active secretary of the Human Betterment Foundation, estimated that 8·12 per cent., or 1 in 12, of the patients admitted to Californian State mental hospitals had been sterilised since the first law was passed in 1909. Up to June, 1926, 1054 sterilising operations had been performed on mental defectives in the Sonoma State Home. Of the sterilised insane, 47 per cent. of the men and 29 per cent. of the women were still under institutional care; the corresponding figures for defectives were 34 per cent. of the men and 28 per cent. of the women. The Brock Committee regards this aspect of the Californian experiment as profoundly unsatisfactory; they can find no justification for sterilising defectives who are unfit for community life.

THE RESULTS

Opponents of eugenic sterilisation usually fear that promiscuity will be increased among the sterilised with consequent spread of venereal disease; they sometimes suggest that sterilisation may cause physical disability to the patient.

The operations performed in California have been vasectomy in the male and salpingectomy in the female. There is little evidence that these measures have produced physical disability in the patient. We are told that "of 89 mentally defective women questioned after salpingectomy at the Sonoma State Home, 70 reported no change in libido, 12 a decrease, 7 an increase. The group which claimed a decrease was more intelligent than the average." It is, of course, important to know whether these patients had been on parole before they were questioned, and, if so, whether they had had adequate opportunity to estimate any change in their libido. This point is not made quite clear in Mr. Popenoe's account. He seems to imply that the women questioned had been on parole and that some of them were married, but there is no definite statement to that effect. He points out, moreover, that the testimony of mentally defective women was not the best evidence on which to base a sound conclusion. Many of them had been sexually delinquent before admission and would therefore be anxious to convince the staff that they were not likely to become sex offenders in the future, and would be inclined therefore to represent themselves as less highly sexed than on admission.

---

[1] Collected Papers on Eugenic Sterilization in California, 1930. The Human Betterment Foundation, Pasadena, California.

Of 36 men committed to the Californian State hospitals for mental disease, 22 noticed no change in their sexual life after vasectomy, 9 reported an increase of sexual activity, and 5 a decrease. None of them experienced any distension or pain in the scrotum following the operation. In this case the information was obtained by sending a questionnaire to patients discharged from the State mental hospitals. As the psychoses affect the sexual life of the patient, recovery from a psychotic state would be likely to lead to a change in libido; so that this evidence is not above criticism. Of a group of 65 normal men upon whom vasectomy had been performed by their own wish, 9 reported that libido was greater than before, 45 that there was no change, and 2 that libido was decreased, and their statements probably deserve to be taken at face value.

Among the cases followed up, there was no evidence that sterilisation had any influence on the failure of patients on parole. Of those patients paroled, about whom information was available, 73 per cent. of the boys were successful and 65 per cent. of the girls. Success was taken as meaning that the interests of society were as well protected as if the patient had remained in the home. In a series of 107 boys on parole, 78 were successful, 1 doubtful, and 28 unsuccessful. Only 9 of the failures showed criminal tendencies, and in 1 alone—an exhibitionist—was there any sexual element. In a series of 304 girls on parole, 189 were successful, 18 doubtful, and 97 unsuccessful. Altogether there were 25 cases (8 per cent.) of sexual delinquency in the series. That is to say, 1 girl in 12 became sexually delinquent when released on parole; but it must be noted that 9 out of 12 of these girls had been sexually delinquent before sterilisation and that the figures showing success on parole compared favourably with those of institutions of other States where sterilisation was not practised. Out of 2000 feeble-minded insane women sterilised, five or six were reported to consider their infertility an asset because it freed promiscuity from the fear of pregnancy. Others, of course, may have said nothing and thought the more. No instance of the kind was reported among 3000 sterilised men, but since society regards the unmarried father more indulgently than the unmarried mother, male patients were presumably indifferent about this point.

The evidence of probation officers who had had the opportunity of observing large numbers of paroled patients over a period of years indicates that sterilisation has not increased the amount of promiscuity but has tended to diminish it, and that the chances of spread of venereal disease have decreased to a corresponding degree.

MARRIAGE AFTER STERILISATION

In one respect sterilisation has been decidedly successful. The marriage of an unsterilised defective patient can only be regarded as a catastrophe to the State, since it is idle to expect a mentally defective person to practise birth control successfully or to exercise self discipline. Many sterilised defectives who marry, however, become more stable and live happy competent lives. This is especially true of the women who, in the Californian experiment, were found to be highly sexed and anxious for marriage; the feeble-minded men, on the other hand, were undersexed and lacking in attraction. Among 129 sterilised patients leaving the Sonoma State Home there were 136 marriages (several patients having married twice). In all except five cases the persons marrying were women. No recent information was available about 29 of the marriages of women, but two-thirds of the remaining marriages were successful—a proportion which is thought to correspond with the average successful marriage-rate in California.

The marriage-rate among insane patients was found to be considerably below that of the general population at all ages. Though the male patients married at all times, the female marriage-rate remained almost constant after the age of 30. In general, it was found that no large group of institutional insane in California would produce enough children wholly to reproduce themselves even if the members of the group were all unsterilised. No comparable statement of the fecundity of the feeble-minded is included, but it is said that among 25 girls successful on parole and now occupied in the management of their own homes, 11 have a total of 45 living children which they had borne, legitimately or otherwise, before sterilisation. This suggests that fecundity was high in the feeble-minded group and that sterilisation has enabled some girls to be released who would otherwise have needed segregation.

THE LONG AND THE SHORT OF IT

Most patients and their relatives appear to be pleased with the results of the operation; out of a series of 173 patients, 132 were satisfied and 22 indifferent; 19 expressed dissatisfaction, of whom only 1 is said to have offered a cogent reason. "In a steadily increasing number of cases," we are told, "the relatives urge sterilisation, or send the patient primarily for that purpose."

But Californian experience is by no means overwhelming evidence in favour of sterilisation. If the insane ordinarily propagate too little to increase the size of their group, and if the parole-rate of mentally defective patients cannot be increased as a result of sterilisation, it looks at first sight as though nothing much had been achieved. The gain, however, though small is positive; for if the birth of even a small number of defective children, or children with a psychopathic tendency has been prevented, it is an advantage. Furthermore, individual patients have undoubtedly benefited by the operation—notably, those women who have married successfully but who would otherwise have had to spend their lives under institutional care. The latest report of the Foundation (Feb. 13th, 1934) suggests that medical officers, probation and parole officers, and social workers are all well satisfied with the operation of the law. Mr. E. S. Gosney, who was responsible for the Californian investigation, sums up the position in the preface to the Collected Papers by saying that sterilisation is not a short cut to any eugenic millennium, but is an invaluable supplement to the recognised protective measures.

THE Marquess of Bath recently opened a new wing of the Bridgwater Hospital. Extensions include a new casualty department, ear, nose, and throat, and ophthalmic departments, a new lecture room for nurses, new private wards and adequate sleeping accommodation for night nurses. The cost has been £11,000.

THE LANCET

LONDON: SATURDAY, JUNE 2, 1934

DEATH AND DAMAGES

THE Lord Chancellor's Law Reform (Miscellaneous Provisions) Bill, designed to remove legal anomalies and uncertainties in the recovery of damages where one of the parties has died, has a special application to claims arising out of road traffic casualties. It proposes to abolish certain recognised injustices, yet apparently it will not take the opportunity to give a much-needed remedy to the hospitals and the medical profession. The origin of this new effort towards law reform is the curious survival of a legal maxim apparently peculiar to the English legal system—namely, the doctrine that a personal action dies with the person. The effect of the maxim has been alleviated by judicial decisions and by statute, and its application to claims based on contracts is incomplete. So far as claims for damages for negligent driving are concerned, the maxim means that the victim of a collision is debarred from all remedy if the negligent motorist dies. It follows that the liability of insurance companies under third-party-risk policies comes to an end with the defendant's death and the principle of compulsory insurance is defeated. Conversely, if it is the victim of the motorist's negligence who dies, his children are prejudiced at present in their effort to obtain damages. It is true that, if the father has been killed, they have a special remedy under the Fatal Accidents Act of 1846, commonly called Lord Campbell's Act; but this statutory remedy is not available for adopted or illegitimate children, nor does it cover medical or funeral expenses. Such are the admitted anomalies for which the Lord Chancellor invited the Law Revision Committee to find a cure.

The distinguished lawyers who form the Committee lately presented a report (Cmd. 4540, H.M. Stationery Office. 2*d*.) and their recommendations were embodied in a Bill which has already been approved by the House of Lords. If the Bill becomes law, death will no longer be a bar to legal claims; all causes of action (except claims for defamation or seduction) on which the dead man might have sued or been sued will survive for or against the benefit of his estate. Nevertheless a notable limitation is to be allowed to remain. If anyone dies as the result of a motorist's carelessness, the dead man's estate will be able to recover only the funeral expenses and certain out-of-pocket payments incurred before death. It will still not be possible to obtain damages for the general loss caused by the death or for the mental and bodily suffering which preceded death. This limitation was officially explained during debate in the House of Lords as being due to the difficulty of calculating the loss or putting a figure upon the suffering. Supposing, said the Lord Chancellor, it was a celebrated surgeon who was killed: it would be hard to assess the loss which his death inflicted upon his estate. To laymen this explanatory argument may sound unconvincing. They are probably aware that, if the celebrated surgeon was merely crippled and not killed by the accident, a jury would be expected to fix the damages due to his enforced inability to continue his practice. Laymen may also be surprised that the Bill proposes to allow funeral expenses to be recovered in such cases but not the expenses of medical or hospital treatment. There is no difficulty in ascertaining medical fees or hospital payments if a patient is alive; why is there to be any difficulty when the patient dies? If the estate of the victim of a fatal motoring accident is to be entitled to recover the funeral expenses from the negligent motorist, why should not the latter also pay the doctor and the hospital as well as the undertaker? Why does the law once more leave the doctor and the hospital to bear the loss?

RADIOGRAPHY OF THE MASTOID IN ACUTE OTITIS

THE indications for operation in suppuration of the middle ear are a perennial source of interest to general practitioners as well as to otologists. Prof. HUGO FREY, in a lecture reported in the *Journal* of the American Medical Association of Vienna,[1] makes some wise comments on the factors which have to be considered. Apart from the very mild cases which do not go on to suppuration, acute otitis is always characterised by a purulent inflammatory process of the mucous membrane which affects not only the mucosa of the tympanic cavity, but the coating of all the other spaces of the middle ear—namely, the Eustachian tube, attic, antrum, and mastoid cells. In most cases the inflammation becomes severe in the first few days after the onset, and spontaneous perforation of the drum membrane does not usually occur until the fourth or fifth day; in such cases it is advisable to incise the membrane as early as possible, since the slight operation not only brings about a more rapid disappearance of the pain and the fever, but doubtless also has a good effect on the intensity of the process. It is important to remember that there are forms of acute otitis in infants in which the temperature is almost the only symptom, and otoscopic examination shows only minimal changes; but in these cases also paracentesis must be performed.

This acute inflammation usually subsides after three or four weeks, and operation is therefore not necessary for the cure of an otitis confined to the mucosa, but only when the process of inflammation spreads to the underlying bone. The usual clinical indication for operation is when, generally about the third or fourth week and after the temperature and pain have disappeared, they set in again; tenderness over the mastoid, which is nearly always present at the beginning of an otitis, comes on again, and the posterior wall of the auditory meatus sinks. Fluctuation over the mastoid is no longer waited for to-day; but in young children, in whom the petro-squamous suture is still open, we are sometimes surprised by the appearance of a retro-auricular abscess. However, the development of an abscess in the mastoid process is not always accompanied by such acute symptoms; there may often be fairly extensive destruction of bone without high temperature or severe pains. Clinically, such a condition can be diagnosed when an acute otitis is not completely cured in the course of four or at the most five weeks. The secretion may continue, if only very slightly, and when there is still a pressure sensitiveness, no matter how slight, at the root or the tip of the mastoid process, abscess must be suspected; it may indeed be present even in cases where there is no longer discharge but the drum membrane is not entirely normal and, which is very important, the hearing capacity has not been satisfactorily restored. The severe intracranial complications may appear even in the first few days in the so-called malignant form of acute otitis, and in such cases surgical intervention is necessary at the very beginning.

---

[1] Ars Medici, 1934, No. 3, p. 99.

The indication for operation in acute otitis can be supported by X ray examination of the bone, but it requires special practice and experience to make correct pictures of the ear, and also to be able to interpret them. The following points are mentioned by **Frey**: a veiling or shadowing of the mastoid cells does not mean that an abscess is present, for this may also be seen in cases of uncomplicated otitis, since the mucous membrane of the cells is always involved in the inflammatory process. It is an entirely different matter when the septa between the cells disappear or become indistinct, for a destructive process can then be assumed with certainty. It is always absolutely necessary to prepare comparative pictures of the healthy side, and in doubtful cases it is advisable to repeat the examination, for this is the best way of recognising a progressive process. In any case, an X ray picture taken before operation gives information as to the extent and form of the pneumatic system and the topography of the adjacent cranial fossæ.

Dr. P. **Cottenot**, of Brussels, recently described[2] the positions which he recommends for radiography of the mastoid. He agrees with Prof. **Frey** that a comparison with the opposite side is essential, that a shadowing with diminution of the transparency of the mastoid cells is to be found in simple acute otitis without clinical signs of mastoid involvement, but that a mastoid focus can be diagnosed when destruction of the intercellular septa is seen. A skiagram of the mastoid is of no diagnostic value unless it shows the details of these septa, which are very delicate and often only slightly visible; such a picture should be sufficiently clear and fine to be examined through a lens. Here more than anywhere in the body the results of radiography must only be interpreted in conjunction with the clinical findings. Dr. R. **Thienpont**, of Antwerp, comes to similar conclusions.[3] In addition, he believes with **Wittmaack** that the course of an acute otitis is peculiarly influenced by the form of pneumatisation of the mastoid process, and that radiography, by showing this, has its principal value in prognosis. According to this theory, a normal or "mesoplastic" mucosa, with complete and regular pneumatisation, is rarely attacked by acute inflammation. Three degrees of hyperplasia of the mucosa are distinguished: (*a*) a highly hyperplastic mucous membrane with complete arrest of pneumatisation is likewise rarely attacked; (*b*) a moderate degree of hyperplasia with partial arrest of pneumatisation is particularly predisposed to acute inflammation; and (*c*) in the slightest degrees of hyperplasia there is but very little tendency to inflammation. A condition of hypoplasia can also influence the acute inflammatory process; thus, the most advanced degrees of fibrosis, often the result of previous inflammation, are not easily infected, but the less extreme hypoplasias do not always escape. Dr. **Thienpont** holds that these various conditions may be recognised by radiography, and that valuable aid to prognosis can thus be given; but it cannot yet be said that his postulates have been proved.

HEALTH INSURANCE AS "SOCIALISED MEDICINE"

The American Medical Association at their annual meeting in Cleveland, Ohio, on June 11th–15th will give special consideration to the question of introducing some form of compulsory health insurance into the United States. Hitherto the Association have strongly opposed health insurance, regarding it as a form of "socialised medicine," even where insurance medical services are provided through the panel system, and therefore repugnant to the rugged individualism of the American people; and any attempts to discuss the subject at the annual meetings have been, if not actually burked, at all events not encouraged. There are now unmistakable signs that the rank and file of the profession are dissatisfied with this way of dealing with so important an issue, and a lively discussion may be anticipated at the Cleveland meeting. For the purposes of the discussion the association's bureau of medical economics has prepared an elaborate report on "The Insurance Principle in the Practice of Medicine," which purports to set out the effects of health insurance on medical practice in Europe. The report, though written with outstanding ability, is, on the whole, a disappointing document. One naturally expects documents written by Americans for Americans to be before all things up to date; and this report, admirable in many respects, is certainly not up to date; it is almost wholly given up to criticisms of the oldest health insurance system in Europe—namely, the German—which from the insurance doctor's point of view is also the most unsatisfactory.

---

[2] Paris Médical, Feb. 3rd, 1934, p. 95.

[3] Bruxelles-Médical, March 18th, 1934, p. 641.

The defects of the German system were well known to the medical profession of this country 25 years ago, and it was to prevent the introduction of those defects into the British insurance system that the British Medical Association entered upon their campaign of the "Six Cardinal Points." The points embodied certain basic principles of insurance medical practice for which the German doctors have for 50 years striven unsuccessfully to secure: separation of medical services from cash benefit administration, statutory right of every doctor to undertake insurance practice, free choice of doctor, selection by local doctors of the local method of medical remuneration, effective participation of doctors in the central and local administration of the system. Medical benefit in the British system has been based on these principles since its inception 22 years ago, and with the introduction of the system health insurance entered upon a new phase; in countries that have since adopted compulsory insurance—France, for example—the doctors have profited by the experience of their British colleagues. At this time of day it is unnecessary to concentrate attention on the German system. It is by an open-minded study of the British system that an inquirer may most readily appreciate the issues involved in the introduction of compulsory health insurance; and it is surprising that the American Medical Association, in a document prepared to furnish the facts most material to the forthcoming discussion, should have dealt so inadequately with what the British doctors have done to place insurance practice on a satisfactory basis. The statements that are made are so brief that some are misleading or inaccurate; it is said, for example, that "confinements" are among the services provided, whereas attendance on a confinement is expressly excluded from the panel doctor's duties—an important point to bear in mind when considering the amount of his remuneration.

We hope that the American Medical Association will supplement their studies in German health insurance by giving some attention to what has been done in this country to bring insurance practice into harmony with the true traditions of the medical profession. After all the Briton is as full of "rugged individualism" as his American cousin, and the spirit that took the *Mayflower* across the Atlantic still lives in the old country, to the irritation of a certain reforming type. Our insurance system was not imposed upon us by a dictator, but freely accepted as a valuable measure of social reform, and in developing the system there is no terror of "socialised medicine," which may mean anything or nothing according to what is in the minds of those who use the phrase.

X RAY DIAGNOSIS OF LOBAR PNEUMONIA

THE importance of radiography in the diagnosis of chronic thoracic disease is now generally recognised and a radiogram is rightly regarded as an essential part of every complete investigation of the chest. Its application to the diagnosis of acute disease has been limited by the difficulty of adapting apparatus suitable for chest work to use at the bedside. In some acute diseases, such as pulmonary abscess or empyema, the slight risk involved in moving the patient from ward to X ray department is so much less than those of a hesitating diagnosis that the lesser of two evils has always been rightly preferred. The portable X ray unit, which enables the physician to obtain a picture of the patient's chest with less strain to the sufferer than is entailed by a physical examination, should facilitate still further the investigation of these types of disease, and even apply to conditions such as pneumonia in which the removal of the patient from his bed entails unjustifiable risks. The provision of a portable set will ease the burden of responsibility resting upon the physician who has had to depend upon physical signs alone to determine whether the patient is suffering from a simple pneumonia or one complicated by sepsis within or without the lung parenchyma. The importance of such early diagnosis in pneumonia has become much more evident since the introduction of Felton's serum. Radiography may also be expected to tell us something of the manner in which pneumonia commences, develops, and resolves.

Interest thus attaches to a series of 40 cases of pneumonia which have been kept under radiological observation at Chicago during the course of the disease. In reporting these[1] the authors have endeavoured to correlate X ray findings with deductions based on the results of physical examinations. Experience gained in recent years from the radiographic study of chronic disease prepares us to anticipate their first and, from the practical point of view, their most important finding. None of the skiagrams taken later than 24 hours after the onset of symptoms failed to show abnormal shadows in the lungs, although at this early stage of the disease abnormal physical signs might be lacking or so slight as to be difficult of interpretation. Further, X rays proved to be more accurate than physical signs in determining the extent of disease until the stage of maximum consolidation was reached, when both methods proved equally trustworthy. The cause for this discrepancy is to be sought in the site of the original pneumonic focus which is generally deeply situated. Lesions so placed may be entirely beyond the reach of percussion and auscultation, as radiograms of tuberculous chests have abundantly proved. A consideration of symptoms and the result of X ray examination may thus enable a diagnosis of pneumonia to be made with some confidence at a stage when neither impaired percussion note, bronchial breathing, nor hair crepitation can be demonstrated.

It must not, however, be supposed that a radiogram of a pneumonic lung will provide a characteristic picture diagnostic of the condition without regard to symptoms or to the patient's general condition, in the way that a skiagram of a chest may supply conclusive evidence of phthisis without reference to history or symptoms or physical signs. There is, for example, little to distinguish the shadow of a consolidated upper lobe in an acute pneumococcal infection from the shadow cast by an epituberculous lesion of a lung. Radiology has further demonstrated the entity of a variety of pneumonia, or at any rate of pulmonary consolidation, which is unaccompanied by symptoms of acute disease or respiratory distress, and is indeed not seldom discovered during the routine examination of the chest of a catarrhal child. Again, an atelectatic lung may be indistinguishable from a pneumonic lung if X ray appearances are alone taken into account. This condition has indeed been held by some to be an essential feature in pneumonia, but no evidence of atelectasis was discovered in any of the cases under review. A slight degree of mediastinal displacement towards the affected side was, however, noted in some instances, though more commonly a slight elevation of the diaphragm was evident. Such changes are evidently necessary to compensate the diminished expansibility of the partially consolidated lung.

ANNOTATIONS

DENTAL CARIES AND ORAL HYGIENE

In an address from the chair at the final session of the third Dental Board appointed under the 1921 Act, Sir Francis Acland said that the most important piece of investigation on the medical side was that which had recently been concluded by Mrs. Mellanby. It was very difficult for any layman, and perhaps for anyone, he said, to give an account of this work, which would at the same time do it justice and satisfy all those interested in the problems investigated, but he would attempt some observations on the subject if only to draw attention to the great importance of the work. Mrs. Mellanby had shown without doubt that teeth of good structure could be produced in certain animals by the administration of a dietary having a low cereal content but rich in vitamin D. Her more recent investigations had shown, in his opinion, that similar results could be produced in human beings. She claimed also that defective structure due to unsuitable dietary and caries in human beings went hand in hand. "I believe," said Sir Francis, "there is strong evidence for this already, and that further evidence will establish it. The question will, however, remain as to the importance of environment as compared with structure, and it will appear to many that in the present state of our knowledge Mrs. Mellanby may be going rather too far when she states that factors other than structure 'may play a part, although a secondary part, in the onset and prevalence of the disease.' We have not, I think, yet sufficient facts for the full elucidation of this problem. There was, for instance, during the investigations conducted upon the effects of different dietaries on children, a considerable increase in the number of carious teeth in the children receiving the dietary which Mrs. Mellanby would recommend, and on this her comment, which I believe to be probably true, would probably be that the special dietary was not started early enough, and should have been applied during the antenatal period and infancy. Further investigation may establish the fact that caries-proof structure can be built up in this way, but the difficulty of securing the right dietary throughout the whole period of tooth formation will, I think, make it unwise to relegate oral hygeine to a definitely inferior position. Its practice, hitherto, as Mrs. Mellanby quite truly says, has not resulted in any marked decline in caries, despite all that has been talked and written about the subject. But this may be due rather to the incomplete way in which the teaching has been applied than to error in the teaching itself. I, for instance, do not find it easy to finish my meals with detergent substances, and I cannot persuade myself that it is not useful to remove from the teeth with a toothbrush that which adheres to them as the result of meals. It would be useful, it seems to me, if it were possible alongside of a more complete experiment which would probably more completely establish Mrs. Mellanby's conclusions as to the importance of diet in structure, to conduct also more complete experiments than any which I believe have yet been possible upon the effects of perfect environment, apart from attention to diet. These comments are not in any way meant to throw any doubt upon the very high value of Mrs. Mellanby's work; on the contrary, I believe that it marks a very great advance towards a final conclusion. It challenges, and rightly challenges, some hitherto prevalent theories, and it must be the basis of all further work on the subject."

HOUSING, POVERTY, AND MORTALITY

The Registrar-General's annual review of the statistics of England and Wales shows year by year that as we move northwards the rate of mortality progressively increases. This relatively unfavourable mortality experience of the north is apparent in each type of administrative area—county borough, urban district, and rural district—and is most distinct in the early years of life, especially the second year. It is not difficult to suggest a number of natural and acquired characters of the more northern areas that may have a bearing upon the greater mortality risk—e.g., colder climate, smoky environment, occupational risks, density of population, and (perhaps) harder economic conditions. The difficulty lies in determining the actual importance of each such factor and in measuring the contribution they individually make to the excess in mortality. A very interesting study of the data has been made by Dr. Percy Stocks in a paper read before the epidemiological section of the Royal Society of Medicine on May 25th. He first notes that if we divide up Great Britain into successive zones of latitude (omitting London), then as we move northwards there is a progressive increase in the mean density per room until the Scottish industrial area is reached, where the density is 86 per cent. in excess of that in the southernmost zone. By statistical means he disentangles the influence of the two factors, latitude and density, and concludes that at ages over 5 there is no reason to suppose that mortality from all causes combined is appreciably affected by climatic differences dependent upon latitude within the limits of England and Wales. The mortality of young children from respiratory disease, however, does show an increase in passing from the south coast to the industrial north, as much as 42 per cent., even after allowance has been made for the effects of the increasing density and crowding per room. Similar, though slighter, changes were observed in infant mortality from causes not congenital, which may be presumed to be due also to the respiratory diseases which form the bulk of these deaths. An analysis of the sunshine records derived from stations in the different latitudes leads Dr. Stocks to advance the belief that these special effects of geographical area upon the mortality of young children are the result of diminished sunshine, which, leading to rickets, lowers resistance to respiratory and other infections.

Apart from this he finds no evidence that the differences in average mortality experiences between different parts of Great Britain can be ascribed to climate, and he turns to a more detailed analysis of the influence of density as measured by persons per acre and persons per room. The latter, he finds, shows the closer association with mortality; in fact up to middle life the importance of crowding per room appears to be almost double that of density per acre. The largest increase in mortality as overcrowding increases is found at ages 1–5, so that it is in these early years that the greatest benefit from improved housing may be looked for; the differences diminish but are still appreciable at the school ages, expand again for young adult females, and then steadily decline with advancing age. To what extent this association of mortality with density per room is due to overcrowding per se is a question of obvious importance, but not one to which a satisfactory answer can be given. Some believe that social selection plays a part, the less fit through their lower earning capacity gravitating to the most crowded houses. Overcrowding is certainly highly correlated with poverty, but it is Dr. Stocks's belief that the whole explanation of the excessive death-rate in the more densely occupied areas is not to be found in economic differences. The disease most likely to react to privation and overcrowding is phthisis, which many workers have shown to be particularly sensitive to social conditions. This association between tuberculosis and poverty has been made the subject of study in the second bulletin issued by the Committee against Malnutrition,[1] where special attention is given to the effects of the present economic depression.

In this bulletin the death-rates from respiratory tuberculosis are compared between the aggregate of 16 specially depressed county boroughs and the remainder of the county boroughs of England and Wales. In the former the mortality has declined between 1925–27 and 1930–32 by 5·1 per cent., in the latter by 9·0 per cent., so that in the more recent years the depressed boroughs were in a relatively more unfavourable position. On the other hand it must be noted that all the towns in this group except one showed an absolute decline in phthisis mortality, though in three the improvement is very slight. These results can hardly be taken as more than suggestive, since crude death-rates are utilised, and it is well known that the decline in mortality from phthisis has affected differentially the various age-groups and the two sexes; further, the method of aggregating the depressed towns may give undue weight to the movements in the larger components and disguise the change in the smaller towns. A much more detailed analysis is essential before we can accept the committee's conclusion (based also upon the reports of various medical officers) that "danger signals have appeared, even in England and Wales, indicating that, in not inconsiderable areas of the country, underfeeding or the other accompaniments of poverty have become sufficient to constitute an insidious danger to public health by influencing the morbidity and mortality of this disease." There appears to be more justification for the deduction from the class inequality of tuberculosis mortality, that the creation of a generally more favourable social background might significantly increase the rate of decline in the death-rate without any further advance in therapeutic knowledge—though the possibility of heritable factors contributing to class differentiation must not be overlooked.

NATURAL PERFUMES

We have received the following notes on the manufacture of natural perfumes, and the writer desires to express his indebtedness to M. J. Henri Moutet, of Grasse, through whose courtesy he had the opportunity of seeing in operation the processes which he describes, and so learnt much as to the methods of an interesting industry which at this particular season of the year is at full blast. He writes:—

"The ancient art of the perfumer still flourishes at Grasse and in the surrounding district. Here the odoriferous principles of plants grown in the neighbourhood are extracted either by steam distillation, extraction direct by solvents, or for the more delicately perfumed ones the old pomade or enfleurage process is employed. Under this process the functional activity of such flowers as jasmine, jonquil, tuberose, and mignonette goes on while they are packed between glazed frames supporting films of beef fat or lard, or on cotton fabric impregnated with olive or mineral oil. The absorption by the fat or oil during the period of exposure yields from six to twelve times the amount of perfume obtained by other processes, and of a finer quality. This, it may be supposed, is due to the continued production of perfume by the plant which is not killed, as in other processes by a high temperature or chemical poisons. Great care is taken to use fats and oils so prepared as to have no bad odour and not to develop rancidity when stored for years. The pomades thus obtained may be used as such for perfuming fatty preparations or may be stored until an 'extrait aux fleurs' is required, when they are extracted with strong alcohol, any dissolved oil is frozen out at a temperature much below 0° C. If the concentrated perfume is required the alcohol is distilled off under reduced pressure, thus avoiding the possible destructive action of heat.

"Distillation in a current of steam from an alembic is used for roots, trunks, branches, bark, previously torn up or reduced to sawdust, for leaves, flowers, and berries which are sometimes crushed first. A variant of the enfleurage process is used for violet flowers (Parma and Victoria), rose de mai, orange flower, and cassia. In this the flowers are digested for an appropriate period in purified fat or oil raised to 60–70° C.; when extraction is considered complete the molten pomade is separated from water liberated during the process and the marc is subjected to hydraulic pressure to remove the last of the pomade from the residual tissues. Extraction by volatile solvents is also used, the most commonly used being petroleum ether of low boiling point (40–50° C.) and almost odourless. The substances to be extracted are lixiviated at ordinary temperature by the solvent, which is then evaporated, leaving 'cires parfumees' which yield cloudy solutions with alcohol and may be purified by freezing and filtration, yielding liquid 'essences absolus.' An intermediate solid product is known as 'essence concrete.'

"Among the plants or their parts which are grown in the Alpes maritimes, the Var, or neighbouring departments, and are treated at Grasse, are: aspic (spikenard), angelica, basilique (basil), camomile, céleri, ciste (rock rose), cypres, estragon (tarragon), fenouil (fennel), genièvre (juniper), geranium, hysope, marjolaine (marjoram), menthe (mint), melisse (balm), oranger feuilles, oranger fleurs, persil (parsley), romarin (rosemary), rose, sabine (savin), sauge (sage), serpolet (wild thyme), tanaise (tansy), chèvrefeuille (honeysuckle), freesia, genêt (broom), jacinthe (hyacinth), jasmin, jonquille, lavande, lys, magnolia, mimosa, mousse de chêne (which is literally oak moss and is recognisable as a much used scent base), muguet (lily of the valley), narcisse, œillet (carnation), reseda (mignonette), rose de Mai, tuberose, violet flowers and leaves. The names of these are mostly obvious, but Neroli, which is an orange scent, is called after its inventor; patchouli is distilled from the dried leaves of pogostemon patchouli, a member of the great scent-bearing order labiacæ, a plant cultivated in the Straits Settlements, Penang, Java, and other tropical places. Owing to adulteration of the Asiatic product the dried leaves are sent to Europe and distilled at Grasse. Cuscus grass (andropogon muricatus) yields ' vetiver ' from its roots, although the leaves are almost odourless, and is imported from India.

---

[1] Published by the committee from 19c, Eagle-street, W.C. 1, May, 1934.

"All the products mentioned are prepared at Grasse from natural sources, which are considered to yield finer perfumes than can be obtained synthetically—in fact, the use of synthetic bodies alone is unusual in the production of high-class perfumery. Most natural perfumes seem to be mixtures of several compounds, products of the vital processes of plants. Although the ketone ionone (usually a mixture of the α and β ketones) is known as artificial violet, it —or its two constituents—is usually mixed with many other artificial and natural odoriferous products in making violet perfumes. It is even doubtful whether this or other synthetic odoriferous compounds actually occur in the plants whose odours are simulated. Their use in many cases is mainly as carriers for the more delicate natural product."

It is evident that there are directions in which the effortless syntheses of living cells hold their own easily against the more violent methods of the laboratory.

CONTROL OF COMMON INFECTIOUS DISEASES

THE current methods of control of the common infectious diseases—scarlet fever, diphtheria, measles, and whooping-cough—were the subject of discussion by the Society of Medical Officers of Health on May 25th, Dr. Charles Porter presiding. Dr. H. Stanley Banks pointed out that, whatever its real utility as a measure of control, the public demand for the hospitalisation of scarlet fever continues almost unabated and, in his opinion, is justified by the prevention of sequelæ which is made possible by adequate treatment. As the result of his experience in a series of some 2500 cases injected with scarlet fever antitoxin by the intravenous route, Dr. Banks is convinced of the outstanding superiority of this route over the intramuscular. The complication rate amongst patients so treated is, he says, reduced almost to vanishing point. This view accords with that of most experienced workers that the early injection of scarlet fever antitoxin has a favourable effect not only on the initial toxæmia but on the complication rate, and permits of an earlier release of the patient from hospital, though this is not admitted by all. There has been within recent years a general shortening of the period of detention from the classical six weeks to four; Dr. Banks finds that after intravenous injection of serum patients may safely be released in about a fortnight, especially if they attend an out-patient clinic or are subject to some scheme of supervision for a week or two longer. In his experience the return case rate is not increased as the result of very early discharge; it has been well under 3 per cent. in his series.

On the question of control of diphtheria Dr. E. H. R. Harries voiced the general opinion that the only adequate method of control is the active immunisation of susceptible children. In view of the continued high incidence and unnecessarily high fatality-rate of the disease he expressed the hope that the introduction of large-scale immunisation might not be unduly delayed in this country. At the present time diphtheria is prevalent, and tends to be of a severe type. Dr. Harries deplored the continued misuse of the swab as a chief means of diagnosis of a clinically recognisable condition. Diagnostic swabbing may lead on the one hand to fatal delay in the injection of antitoxin, and on the other to the erroneous diagnosis of diphtheria in patients who are harbouring harmless diphtheroids. Patients diagnosed clinically should be sent into hospital at the earliest possible moment, he said, or at least they should be given antitoxin pending diagnosis. Several medical officers of health spoke of the difficulty of persuading practitioners not to wait for the result of a swabbing before injecting antitoxin. Dr. Harries thought that the reluctance to inject serum was largely due to exaggerated fears of anaphylaxis based upon the use of the older unconcentrated sera which were relatively rich in foreign proteins. Intravenous injection of massive therapeutic doses of concentrated serum even in potential sensitives very rarely gives trouble, and even when signs of anaphylaxis are observed injection of adrenaline, which should always be at hand, speedily clears them up. The injection prior to tonsillectomy of a combined prophylactic dose of diphtheria and scarlet fever antitoxins, with a view to the prevention of post-tonsillectomy diphtheria or scarlet fever, is now the practice at some of the London tonsil and adenoid clinics. Dr. Harries holds that the best procedure is to do preliminary Schick and Dick tests and inject only the specific antitoxin indicated by the results. For the carrier state he advocated rational surgical measures according to the type of nasopharyngeal abnormality discovered. True intermittency of the carrier state amongst convalescents was said to be rare, spurious intermittency, caused by contact reinfections in the ward, being frequent. It is desirable to nurse convalescent carriers in cubicles or in the open air. Indiscriminate swabbing for the detection of carriers in the community is now recognised as futile. For the control of outbreaks in institutions swabbing is a necessary procedure, but it must be combined with virulence tests and Schick tests in the way devised by Eagleton, Okell, and O'Brien.[1]

The control of measles by the use of convalescent or adult immune serum was discussed by Dr. William Gunn, followed by Dr. J. E. McCartney, who demonstrated the apparatus used for the collection of blood in the L.C.C. service. Both speakers stressed the value of convalescent serum either for temporary prevention or attenuation of the attack, and of adult immune serum for attenuation rather than prevention. It was pointed out that now, when an extensive epidemic of measles in London is terminating, is the time to collect large supplies of serum for use in the next epidemic. Dr. Gunn, while agreeing that parental whole blood was a reliable means of prophylaxis in the absence of serum, mentioned two objections which might be raised to its use: (1) the large amount—30 c.cm. as a minimum—which was necessary, and (2) the fact that the injection produces an artificial hæmatoma which takes some time to disappear. Discussing the hospitalisation of measles, Dr. Gunn insisted that in order to avoid post-admission complications ample bed spacing is necessary, and that free use should be made of barrier nursing. Better still, he thought, children should be nursed in cubicles or small ward units containing not more than four cots, or on balconies or verandahs. He advocated ample provision for stay in convalescent hospitals when the acute stage was over. With regard to whooping-cough, no reliable advance in therapy seems yet to have been made, but in the experience of some workers abroad fresh vaccines suitably prepared and injected in sufficient dosage had given promising results in prophylaxis.

THE SURGEON AND THE GUNMAN

In discussing last week certain aspects of professional secrecy it was observed that the doctor's problems in this respect are by no means merely academic. Perhaps the most romantic of the situations about which the medical student is instructed is that of the hunted criminal who comes to physician or surgeon for treatment of his injuries. A classic example is now reported from America by the *Times* correspondent in New York. John Dillinger, the notorious gunman whom the forces of the law are seeking to apprehend, was apparently treated some weeks ago by Dr. Clayton May, a Minneapolis physician, for a gunshot wound. Did Dr. May inform the police? He did not. Consequently he was charged, together with Dillinger's sweetheart, before a Federal Court jury in St. Paul with the offence of conspiracy to harbour a criminal. Each of the accused was sentenced to undergo two years imprisonment and to pay a fine of 1000 dollars. A nurse who acted under Dr. May's directions was tried on the same charge and acquitted.

A country must protect itself against its public enemies; a doctor does not cease to be a citizen. For Dr. Clayton May, however, there was only one question. Did John Dillinger come to him for treatment trusting in his professional honour? The answer is obvious, and Dr. May's colleagues in every country will applaud his action in not betraying a professional trust.

INTENSIVE INSULIN AND GLUCOSE TREATMENT OF DIABETES

The conception of diabetes mellitus as a condition of pancreatic exhaustion is one which it becomes progressively harder to reconcile with all the facts. Prof. Arthur Ellis has lately described [1] a phenomenon which is difficult if not impossible to explain satisfactorily by this theory, and which may prove of no little importance in the understanding of the disease. In certain cases of diabetes under treatment wide variations occurred in the blood-sugar values, rendering them difficult to control, and it was thought that this might be due to depletion of the stores of hepatic glycogen. An attempt was accordingly made to remedy this by the hourly administration of glucose and insulin and somewhat surprising results were obtained. It was found first of all that very large amounts of carbohydrate could be dealt with in this way; and secondly, that there was a considerable temporary increase in carbohydrate tolerance. This was most striking in young subjects whose disease was of relatively short duration; in one case (that of a boy of ten) over 600 g. of glucose were given in the 24 hours, with 10 units of insulin hourly, and it was found not only that the boy became hypoglycæmic on this régime, but that a subsequent sugar-tolerance curve showed a fasting value of 0·054 and a rise to only 0·200 after 50 g. glucose. In another instance it was possible to reduce the insulin required to keep the patient sugar-free on a standard diet from 192 units daily before treatment to 9 units daily afterwards. Ellis reports eight cases treated in this way for a variable number of days, and in all but one a definite increase in carbohydrate tolerance took place during or after treatment. The improvement seemed to be progressive almost from the onset of treatment and to reach a maximum in about twelve days. Except in two cases (both of them early) the improvement was only temporary, but in none was there any evidence that the diabetic condition had been made ultimately worse. No further improvement occurred with a second course of intensive treatment which was given to two of the eight patients.

In considering his findings in relation to present theories of the pathology of diabetes, Prof. Ellis points out the difficulty of explaining the increased tolerance as due to an increased output of insulin by the patient on a high carbohydrate diet, since it is generally supposed that carbohydrate stimulates the output of insulin by raising the blood-sugar, whereas these patients tended rather to be hypoglycæmic during the period of treatment. Again, it is recognised that when small doses of insulin are given frequently, the glucose-equivalent of a unit is higher than when larger doses are given once or twice a day.[2] That this was not a complete explanation, however, was shown by control injections without glucose, after which the improvement was not comparable to that seen when glucose-insulin therapy was combined. Prof. Ellis's findings might be explained on the theory recently put forward by H. P. Himsworth [3] that insulin as secreted by the pancreas is an inactive material requiring activation by some unknown substance ("insulin kinase") produced by the liver. At present, however, there is no direct evidence that an increased activation of insulin occurred in these cases as a result of the intensive glucose-insulin therapy. Whatever the explanation of the increased carbohydrate tolerance may prove to be, it certainly seems to offer experimental support to the use of high carbohydrate diets in the treatment of diabetes.

ILLICIT TRAFFIC IN NARCOTIC DRUGS

Bulgaria has been suspected [4] of being the source of much of the illicit traffic in narcotics which has found its way into other countries of Europe and into Egypt. Quite recently some ten secret factories of morphine and heroin have been unmasked, mainly through the vigilance of T. W. Russell Pasha, director of the Central Narcotics Bureau and commandant of police at Cairo. Not only has the production of the opium poppy been greatly augmented during the past year, but it is alleged that not less than 3000 kg. of heroin have been manufactured in Bulgaria during the current year. Russell Pasha, in his annual report for 1933, states that the convicted addicts undergoing imprisonment in the State prisons of Egypt had fallen from 5681 in 1929 to 674 on Oct. 1st, 1933. He gives a list of 26 gangs of illicit traffickers in narcotics operating in Egypt which have "been tracked down and disposed of," and claims that the narcotic menace which threatened Egypt five years ago has been removed. Nevertheless, large quantities of illicit opium continue to be exported from Turkey, and the practice of eating opium is said to be spreading in the districts adjacent to Port Said and the Suez Canal. While the export of Syrian hashish has been checked, large quantities of Turkish hashish, which is richer in resin and aroma, are smuggled into Egypt. Although the Opium Advisory Committee and the Permanent Central Opium Board of the League of Nations have done much to expose and restrict the contraband traffic in narcotics, Bulgaria, and in the Far East, Manchuria, continue to be the producers of narcotics vastly in excess of the legitimate medical requirements of the whole world.

A MENTAL DEFICIENCY COLLECTION

THE library of the Royal College of Surgeons of England has recently acquired a collection of reports with full details and photographs of all the mentally deficient children—about 4000—admitted to the Fountain Hospital, Tooting-grove, under the Metropolitan Asylums Board from 1914 to 1927. These reports are classified and indexed, and are supplemented by a large series of published papers on mental deficiency from all parts of the world, regularly increased and kept up to date. The whole material is available for readers in the college library from 10 A.M. to 6 P.M. daily (Saturdays 10 A.M. to 1 P.M.), and the compiler and donor is willing to meet students by appointment. The librarian, it is stated, will be glad to have reprints of articles on mental deficiency or allied subjects for inclusion in the collection.

SUCCESS OF SPINAL ANALGESIA

Two papers lately published in widely distant cities bear testimony to the assured position which spinal anæsthesia has at last attained. One of them which has a special interest in connexion with the Royal Society of Medicine's debate on anæsthesia for urological surgery, reported in our issue of May 5th (p. 961), deals with spinal analgesia in the Bellevue urological service, New York, during the years 1925 to 1930 inclusive.[1] Local anæsthesia is the method of choice in this institution and operations which cannot be performed with infiltration are carried out whenever possible with spinal injection. The number of spinal injections reported on is 1490, of which 75 were for cystoscopies and the remainder for urological operations—on the prostate, kidney, and so on. The only fatalities were in persons almost moribund from sepsis and uræmia, and of these only two died in the operating theatre. Novocain was the agent used for all operations lasting not more than one hour; for the longer proceedings Nupercaine in 1 in 200 solution was employed. The patients receive morphia gr. ¼ before going to the operating theatre, and if the systolic pressure is found to be less than 100 mm. Hg, 50 mg. ephedrine hydrochloride intramuscularly; the spinal puncture is not made till the pressure has reached at least 100. The details given show excellent results from the technique adopted.

The other paper[2] comes from Sydney, New South Wales. The author has given over 2500 spinal injections for analgesia without a single death attributable to the anæsthetic. He is a strict follower of the technique originally introduced by Barker, but has reduced the diameter of Barker's instruments. He too employs ephedrine as a routine measure for preserving blood pressure and he uses Percaine in 1 in 200 solution in 6 per cent. solution of glucose. Not more than 2 c.cm. of this solution is needed, even when high analgesia is desired. He deprecates any form of preliminary medication and believes in securing the patient's mental quiet and intelligent coöperation by judicious conversation with him beforehand. Strict attention is given to the patient's posture just after injection, and this is shown in illustrations.

THE HOSPITALS YEAR-BOOK, 1934

THE Central Bureau of Hospital Information had no easy task before it when it took over the publication of "Burdett." We have now before us the fourth issue of its successor, "The Hospitals Year-Book," the object of which, in Sir Arthur Stanley's words, is to help all engaged in the administration of medical charities to compare notes and by the interchange of experience to promote economy and secure uniformity. The information required for this purpose can be obtained only by the willing coöperation of the hospitals themselves, and whereas for the most part this has been freely given in the spirit in which it was asked for, in other cases urgent entreaties failed to elicit the information. The difficulties have resulted in the delay of the Year-Book to a date nearly eighteen months after the end of the financial year to which it refers. It is a pity that this is so, for the Central Bureau is in a position to inquire into many of the problems that must interest all hospital administrators. What is the optimum size of a hospital? What is the ratio of nurses to patients? What is the productivity of this or that form of raising money? What expenditure will this or that system of heating and lighting involve? These and other questions are put by the Bureau for the clear and definite purpose of providing material with which to help administrators to carry out their work more effectively. We are happy to add our word to the appeal of the editor, Mr. R. H. P. Orde, B.A.—who is also hon. secretary of the British Hospitals Association—to the voluntary hospitals both in Great Britain and Ireland to coöperate as promptly and as fully as they can with the work of the Central Bureau. Nothing has done more to retain the support and confidence of the public in the voluntary system than the work of the associations represented at 12, Grosvenor-crescent, S.W. 1.

ON Tuesday next, at 5 P.M., Prof. O. L. V. S. de Wesselow will give the first of his Croonian lectures before the Royal College of Physicians of London. The subject will be arterial hypertension, and the following two lectures will be delivered at the same hour on June 7th and 12th.

THE eighth annual Macalister lecture will be delivered at the National Temperance Hospital on June 21st at 9 P.M. by Dr. Robert Hutchison. The subject is Praise and Dispraise of Doctors. The lecture is free to medical practitioners and to their friends of either sex.

THE series of articles on Prognosis contributed by invitation will be resumed on June 16th, when Dr. Reginald Miller will write on the Prognosis in Juvenile Rheumatism.

Sir Gowland Hopkins, P.R.S., will take the chair at a meeting arranged by the Committee against Malnutrition for Wednesday, June 13th. As announced in our last issue, this meeting is called to discuss the steps to be taken in combating "the widespread undernourishment of men, women, and children," and the speakers will include Dr. R. D. Lawrence, Dr. R. A. Lyster, Dr. Stella Churchill, and Prof. J. B. S. Haldane. It will be held at 8 P.M. at 34, Red Lion-square, W.C., and tickets may be had from the hon. secretary of the committee, Mr. F. Le Gros Clark, at 19c, Eagle-street, W.C.1.

THE PREVENTIVE ASPECTS OF MEDICINE

A Series of Lectures in progress at King's College Hospital Medical School

XXIV.—PRINCIPLES OF IMMUNISATION AND PREVENTIVE DISEASE

THE general principles of prophylactic immunisation may seem to come a little intrusively into a course of lectures that has dealt, in the main, with practice rather than with theory; but there have been many references to the application of the mechanisms concerned in specific immunity, and something is certainly to be gained by getting a clear picture of the way in which these mechanisms act. With such a picture in our minds we are, at least, more likely to use our instruments intelligently, and therefore successfully, and less likely to expect them to work under entirely inappropriate conditions.

If the picture is to be useful as a working diagram it must be clear; and if it is to be clear it must be sketchy. It must, indeed, depart in places from any strict canon of scientific accuracy; for this would demand that outlines should often be blurred, and shaded with provisos and exceptions, whereas we want them hard and clear. We must, then, for our present purpose, adopt the method of didactic simplification, adopting some theories as facts and ignoring awkward exceptions to rules. This will not matter so long as we are frank about it, taking our picture as a provisional working plan, subject to alteration if and when modifications become necessary. For the same reason it will be convenient to assume an almost blank ignorance of the mechanisms with which we are concerned, since once we begin to leave things out because they seem too simple and elementary it is difficult to know where to stop. Again, it will simplify matters if we omit all reference to authorities, and leave our summary of facts and theories undocumented.

Mechanisms of Antibacterial and Antitoxic Immunity

The mechanisms with which we have to deal are, in their essence, very simple. When certain foreign substances—substances to which we give the generic name of *antigens*, and which include bacteria, viruses, and toxins—gain access to the tissues, they stimulate the production of a particular kind of serum protein that is known as an *antibody*. The essential quality of an antibody is the presence of a specific chemical group, or arrangement of groups, that enables it to combine with the antigen, and, in so doing, to alter its physical and chemical properties.

The body makes use of this mechanism, which was probably developed in the first place for quite different ends, in protecting itself from infective disease. The antibodies that are formed when bacteria, or viruses, or their products, gain access to the tissues react specifically with them, rendering them relatively or wholly innocuous.

In the case of a toxin the result of the antigen-antibody union is neutralisation—neutralisation in the immunological sense, for there is little evidence that the toxic chemical grouping is itself destroyed or chemically changed. This neutralisation is accompanied by the flocculation of the toxin-antitoxin compound. It may be, though it is at present no more than a guess, that the innocuousness of this compound depends on its low diffusibility.

In the case of bacteria, or virus particles, the antigen-antibody union occurs on the surface of the parasite and results in the deposition thereon of scattered or continuous patches of antibody globulin. This change in the nature of the bacterial surface has important secondary results. The bacteria tend to adhere together, they are more easily ingested by phagocytic cells, and, in some cases, they become sensitive to a serum constituent known as complement, which produces a type of disintegration known as lysis. As a consequence, bacteria or viruses that would, in their unaltered state, become widely dispersed throughout the tissues and multiply freely in them are, when sensitised by a specific antibody, retained and held in check either in the immediate neighbourhood of their portal of entry, or in specialised tissue areas such as the lymph glands, the spleen, the liver, the bone-marrow, and so on, that contain depôts of active phagocytes of the reticulo-endothelial type.

But though we should always keep antitoxic and antibacterial immunity distinct in our minds, and can sometimes separate them in practice, we are often concerned with infective diseases that have both toxæmic and invasive characters. In such cases we may be able to alter the disease syndrome, by eliminating the toxæmic element, even though we fail to prevent those pathogenic activities of the parasite that depend on tissue invasion.

The differentiation between toxæmic and invasive effects suggested by such statements as these is, however, over precise, useful though it is for purposes of description and argument. Bacterial invasion would do no harm if the bacteria were not in some way toxic in themselves, and we must suppose that they injure the host's tissues by a variety of mechanisms which must, in the final analysis, be of a chemical nature. The real differentiation is between the immunity that can be developed to particular toxins that are freely liberated from the bacterial cells and diffuse widely throughout the tissues and the immunity that depends on limiting the dispersion and activities of the bacterial cells themselves, with all the other toxic mechanisms that they have at their disposal.

We may note that antibacterial immunity, in part because it depends on the interaction of many factors of which immunisation affects only one, in part because the living bacterium has methods of counter-attack that a non-living toxin has not, tends to be less consistently effective than the antitoxic form. Antiviral immunity, which is determined by the same general factors as the antibacterial type, though perhaps with minor modifications, is often conspicuously effective.

Methods of Exploiting Specific Immunisation

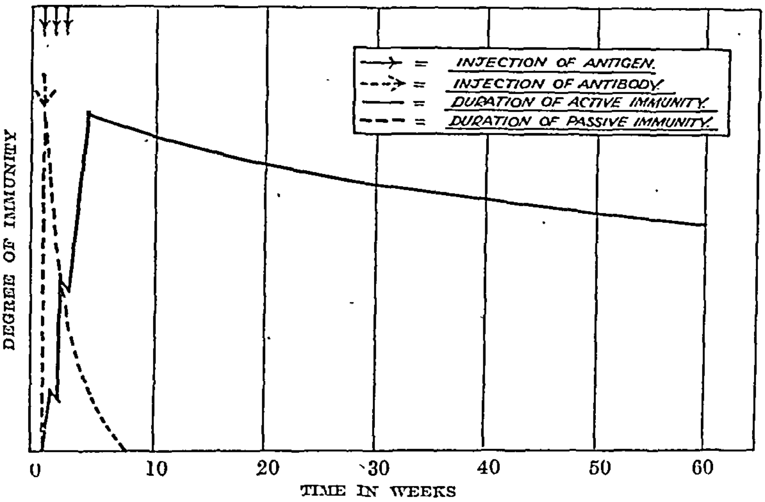
Before passing to the essential problem of specificity, which determines among other things the differentiation between antitoxic and antibacterial immunity that has been referred to above, we may consider in very general terms the ways in which we may exploit the mechanisms that we have outlined, limiting ourselves to prevention, and leaving the treatment of established infections out of account.

The thing we have to do is to provide a person with an adequate supply of the required antibody, or antibodies, and we can do it in two ways. We can make him make his own, by injecting the appropriate antigen. That is active immunisation. Or we can use some conveniently large animal, such as the horse, as an antibody factory, injecting into it the antigen with which we are concerned, and we can then provide the person to be immunised with the necessary antibodies ready-made by injecting into him the serum proteins of the previously immunised horse. That is passive immunisation.

Our choice of method is determined by the time relations of these two procedures. Active immunisation takes time. One dose of antigen may have little effect. If it does it will be several days at least, and sometimes weeks, before any effective immunity is induced. More often at least two injections are needed, at about a week's interval; and there is again a further interval before effective resistance is established. This, for instance, would seem to be the case in prophylactic vaccination against typhoid fever. Sometimes three, or four, or more inoculations are required before the desired result is attained, as, for instance, in the immunisation of certain persons against scarlatinal toxin.

To set against this relatively slow induction of active immunity there is the fact that such immunity, once induced, is relatively lasting. Our information as to how long it lasts is, in fact, much less precise than many written and spoken statements would lead one to suppose. *But it* certainly lasts for months in most cases, often for some years, and it may be for a decade or more. Its relatively long duration depends in part on the fact that the antibody in this case consists of a modified type of the person's own serum protein, and as such is probably not eliminated from the blood and body fluids at a rate greater than the normal turnover of serum proteins, whatever that rate may be. In greater part it rests on the fact that the formation of antibody outlasts the stimulus provided by the injection of the antigen, as may be shown by bleeding an immunised animal extensively and finding that the serum proteins, formed to make good the loss, contain a proportion of antibody little if any lower than before the bleeding. In greatest part, perhaps, it depends on the fact that in the actively immunised person a habit of rapid response to a particular antigenic stimulus has been established, so that any subsequent entry of that antigen into the tissues, as in an incipient infection, is followed by a prompt and vigorous production of antibody.

FIG. 1



The time relations of passive immunity are very different. The full protective effect of the injected antibody is established at once, but this effect is relatively transient. The antibody is usually a foreign protein. As such it is eliminated from the blood and tissue fluids more rapidly—in some sensitive persons much more rapidly—than the autogenous antibody proteins formed in active immunisation. Moreover the total amount of antibody available is limited to the amount injected. No more is formed, nor does the passively immunised person respond with any increased briskness to any subsequent entry of antigen into the tissues. The duration of effective passive immunity is, indeed, an affair of weeks, and usually of a few weeks. Fig. 1 shows approximately the time relations of the two types of reaction, the height of each curve corresponding to the degree of immunity existing at any given time period, and the times of injection of antigen or antibody being indicated by arrows.

The practical implications are obvious. We shall use the method of active immunisation whenever the persons to be immunised are likely to be exposed to risk over a long period, and when the immediate risk is not so great that the delay of a few days or weeks in the induction of immunity is a serious factor.

Thus we use this method in vaccination against small-pox, in infancy or at later ages, in antityphoid vaccination designed to protect troops or others proceeding to areas where this disease is frequent, in mass immunisation against diphtheria and so on. We use it, too, in some cases in which the risk is an immediate one, or in which it has already been incurred, since experience has shown that, under certain conditions, the advantage of durability outweighs the slight delay in induction. Thus, when an outbreak of diphtheria starts in a boarding school, or in a similar institution, the susceptible, Schick-positive children must be regarded as having been exposed to risk at the time the first case is diagnosed. We could protect them passively with antitoxin, but this would leave them susceptible to subsequent infection. It is generally regarded as better practice to induce an active immunity in all susceptibles, controlling this procedure by the examination of throat swabs, and promptly administering antitoxin to any susceptible child found to be carrying virulent *diphtheria bacilli* and showing any clinical signs of infection. Similarly, experience has shown quite clearly that a small-pox epidemic may be successfully *circumscribed by the* immediate vaccination or revaccination of all contacts, followed by a general vaccination campaign in the locality. It would seem that in this type of prophylactic vaccination, in which a living virus is employed, the induction of immunity is sufficiently rapid to prevent or modify the clinical infection, even when exposure has already occurred.

The use of passive prophylactic immunisation will be limited to those instances in which we are concerned with a specific risk of infection, occurring at a known time and unlikely to continue, or to be repeated, once this particular period has passed.

A good example is the use of passive prophylactic immunisation in tetanus. A man suffering from a severe and badly soiled wound, incurred in warfare or in any of the major accidents of civil life, runs a risk of contracting this disease. The administration of tetanus antitoxin, repeated at weekly or ten-day intervals for a few weeks, obviates or greatly reduces this risk, and since the risk is certainly not continuous, and, if unfortunately repeated, can, with certain limitations, be dealt with in the same way, the fact that immunity is of short duration does not matter. Sometimes we use this method in prophylaxis against diphtheria, as when a case of this disease accidentally gains admission to the children's ward of a general hospital, and it is more important to prevent the immediate spread of infection to other sick and susceptible children than to secure for them a more lasting immunity. In the case of scarlet fever this method of controlling a ward epidemic by passive immunisation is still more clearly indicated, because active immunisation is here a longer and less certain process.

Perhaps one of the best examples of the successful exploitation of passive prophylactic immunisation is the success that has been achieved by the use of convalescent or adult human serum in measles. By this means, provided that an adequate dose is given during the first five or six days after exposure to infection, it is possible in the great majority of cases to prevent the development of the disease. But, though the attack is prevented, the child becomes fully susceptible again after a few weeks; and, since future exposure to risk is almost a certainty, the procedure is often modified, except in the case of very young or sickly children, by giving a smaller dose of serum at a rather later date. The usual result of this procedure is that a clinically trivial attack of the disease develops and that the child is endowed with a lasting immunity to reinfection. The method affords a good example of mixed active and passive immunisation.

Specificity of Active and Passive Immunity

And now, after this brief sketch of the mechanisms concerned and the ways in which we exploit them, we may turn to a factor that is central to our whole problem, and which, for that reason, demands rather more detailed consideration. If this part of our discussion seems, in some aspects, a trifle academic, it is at least severely practical in its implications.

The harmful agents with which we are here concerned are bacteria, or viruses, or their products. The important thing about them from our present point of view is their size—not their smallness, but their bigness. We are dealing with cells, or particles, or molecules, that vary in diameter over some such range as 2μ to 0·004μ, if we regard them as spheres, or over a comparable range if we allow for departures from the spherical form. If, to avoid unnecessary decimals, we express size in terms of Angstrom units, these figures become 20,000 Å to 40 Å. However small these may be in relation to the visual power of the human eye, they are big things as looked at by an atom, or by any small group of atoms. The carbon atom, for instance, has a diameter of about 1·5 Å. There is room for many different chemical groupings on the surface of the smallest particle with which we have to deal, room for still more on the smallest virus, and for a vast number on an average-sized bacterium.

We must think of the surfaces of these particles, viruses, or bacteria, not as smooth and homogeneous, but as irregular, patchy, and studded with projecting chemical groupings, and it is the nature and arrangement of these groupings that determine all the reactions with which we are here concerned. Perhaps a fair simile would be an island with irregularly dispersed patches of a varied and rather formal vegetation. But it would be a spheroidal or cylindrical island, with the patches of vegetation all over it; and we should think of it as totally submerged, because, in all the reactions with which we are concerned, our particles or bacteria are suspended in a watery fluid. The sea-bottom on a pebbly or rocky shore, where there are numerous attachments for marine growths, is, perhaps, not a bad image of part of a bacterial surface.

The two objects in Fig. 2 afford very crude and imperfect models of the kind of surface that we must keep in our mind. Let us, for convenience of reference, call the left one A and the right one B. They are definitely misleading in regard to the relative size of the cells and of the active chemical groupings that they bear. If we wished to preserve anything approaching due proportion, we should have to regard them as molecules of some bacterial product, rather than as intact bacteria or viruses. To represent to scale an entire bacterial surface with active chemical groupings of a similar size would entail making a model several feet in diameter, but our smaller models will serve our purpose, so long as we remember that they are grossly out of scale. Those who are familiar with the modern concepts of structural organic chemistry will be able to construct far more adequate images for themselves. Those who are not, but would like to be, will find in a recent monograph by Dr. J. R. Marrack an admirable summary of the essential data.

There are various chemical groupings represented on the surface of these bacteria; but some of them have been given special prominence. We will suppose that these prominent groupings have a dominant rôle in determining the physical and chemical characters of the surface, and that it is the union of antibody protein with these groupings that sensitises the bacteria and renders them susceptible to the defence mechanisms that we have described above. In order that this union may occur the antibody protein must carry groupings having a chemical affinity to those present on the bacterial surface, and it is probable that the spatial arrangements of the active groupings on the large antibody molecule, as well as their individual nature, plays a significant part; since if the pattern of these groupings on the antibody is the same as the pattern on the antigen the surfaces will fit neatly together, with the corresponding groups in apposition, while if the pattern is widely different the fit will be a bad one. In any event, the relation between antigen and antibody is strictly specific, as specificity is understood by the organic chemist; and an antibody that will effectively sensitise organism A will have no effect on organism B. In Fig. 3, A and B are supposed to have been immersed in an antiserum prepared by immunising an animal against A. Antibody protein has been deposited on the specific antigenic groupings that dominate A's surface; but the surface of B remains unaltered. If A gained entry to the tissues of a person endowed with this antibody in adequate amount it would be arrested at or near its site of entry. If B gained entry to the same person's tissues it would multiply and give rise to a widespread infection.

Practical Limitations Imposed by Specificity

We cannot immunise a person against organism A by injecting organism B, nor against B by injecting A. We must keep this essential point clear in our minds. We must not, as immunologists, think in terms of diseases, of enteric fever, or pneumonia, or colds in the head, nor even, as we shall see, in terms of bacterial species, of pneumococci, or hæmolytic streptococci, or staphylococci, we must think in terms of antigenic groups and patterns. But the clinician or the medical officer of health does not want to immunise against an antigenic group or pattern. He wants, quite rightly, to prevent enteric fever, or pneumonia, or colds in the head; so that, for practical purposes, we must take the problem as he looks at it, and see how it looks to us in the light of our own immunological data.

The answers we get are simple and definite enough, though some of them may be disappointing. When we are reasonably sure that a particular disease is caused by one, and only one, bacterial species, and that bacterial species contains one, and only one, antigenic type, then immunisation against that antigenic type should be equivalent to immunisation against the disease. But where a given disease is caused by bacteria of different antigenic types—whether these types differ in other ways so that they are regarded as different bacterial species, as in the bacilli of the typhoid-paratyphoid group, or whether they are classified as different types within the same species, as in the different types of pneumococci—then immunisation against any one type is not equivalent to immunisation against the disease, and its relative effectiveness or ineffectiveness will depend on the relative importance of that particular antigenic type in the causation of the disease. If, for instance, the disease were caused by not more than two or three antigenic types we might, by the injection of one of them, produce an appreciable reduction in the incidence of the disease as a whole. What, of course, we actually do, is to try to include in our vaccine all those types to which a person is likely to be exposed. If these number only two or three the problem is easy, but where the number of types is very large we can hardly hope to obtain the same result, partly because there is a limit to the number of different types that can be effectively combined in a vaccine, partly because the relative importance of different types may vary from place to place and from time to time.

Specificity in Relation to Antitoxic and Antibacterial Immunity

It will be noted that, in our discussion of immunological specificity, we have so far confined our attention to antibacterial immunity. What happens when we bring antitoxic immunity into the picture ?

Fig. 4 shows our same two antigenic types of bacteria, but we will now suppose that they are of the kind that produce a soluble toxin that passes freely from the bacterial cells to the body fluids, and we will represent this toxin by smaller particles bearing antigenic groups that are the same for each particle of toxin, but different from the antigenic groups on A or B. We have chosen to suppose that the two antigenically different bacteria produce the same kind of toxin, and this is a useful supposition because it corresponds to what actually occurs with such an important toxin-producer as the diphtheria bacillus, of which there are many different antigenic types, all producing the same toxin. The same is true of the tetanus bacillus, and, as we shall see, of hæmolytic streptococci. It may, indeed, so far as our present knowledge goes, be regarded as the usual state of affairs.

Suppose that these organisms and the toxins they produce are brought into contact with a serum containing antitoxin but no antibodies acting on the bacteria themselves. Antibody protein will unite with the particles or molecules of toxin, as in Fig. 5, but the bacteria will not be affected. If the bacteria are of the kind that have little invasive power, as is the case with the diphtheria bacillus, then a person possessing this antitoxic antibody will be effectively immune to the clinical disease because, although the diphtheria bacilli that gain access to his throat will not be interfered with, any toxin that they produce will at once be neutralised.

Let us now suppose that our organisms are not diphtheria bacilli, but some organism that has invasive as well as toxigenic powers—say, for instance, two antigenic types of hæmolytic streptococci. We shall, by inducing an effective antitoxic immunity, change the disease without necessarily preventing it, since we shall eliminate only one part of the total clinical syndrome. If we take as an instance scarlet fever, we shall approximate to prevention in the clinical sense, because the erythrogenic toxin is responsible for so much of the classical syndrome of the disease, including the characteristic rash, that what remains would hardly be included in the same clinical category. We shall, however, be left with cases of tonsillitis, sometimes complicated with otitis, that would have been regarded as scarlet fever if the rash and certain other lesions had not been suppressed.

If, however, the type of infection is one in which the invasive activity of the organism is far more important than its toxigenic action, then we should expect little success from antitoxic immunisation.

It is customary, in antitoxic immunisation against such diseases as diphtheria and scarlet fever, to use as our immunising agent a culture filtrate that contains the toxin but not the bacterial bodies. In the case of diphtheria we treat this toxic filtrate to make the toxin harmless, though still antigenic. In the case of the erythrogenic toxin of the hæmolytic streptococcus we usually employ the unaltered toxin, because, in suitable graded doses, it produces no serious toxic effects. In neither case do we make any attempt to induce an antibacterial immunity. We could do so, by injecting bacterial cells as well as their soluble toxin, but it would be of little avail, because we should be frustrated in our attempt to add an antibacterial to our antitoxic immunity by the multiplicity of antigenic types.

FIG. 2

FIG. 3

Suppose that, in order to protect against the invasive as well as the toxigenic effects of the hæmolytic streptococcus, we injected bacterial cells as well as toxin, using a streptococcus of the A type, Fig. 6 indicates the kind of result that we should obtain. If the person immunised were exposed to infection with a streptococcus of Type A all would be well. The toxin would be neutralised and the streptococci sensitised. But if the streptococcus were of Type B, or of any other type except A, there would be no protection against its invasive action ; and, since the different antigenic types of pathogenic hæmolytic streptococci are in fact very numerous, there seems no immediate hope of inducing an effective antibacterial immunity against the various infections to which they give rise.

The Concord between Expectation and Experience

So far we have been considering our practical problems in the light of our immunological data, and we have been concerned with one particular type of mechanism, and with that only. We have no right to assume a priori that it is the only mechanism at work, and we must be prepared to reconsider our working hypothesis, if the results obtained in properly controlled trials carried out in the world outside our laboratories are not in accord with our expectations. We may, therefore, usefully conclude our discussion by a brief reference to a few of the instances in which the available records allow us to test our conclusions in this way. Some of the relevant evidence has been referred to already, for illustrative purposes, but repetition is often difficult to avoid, and is occasionally excusable.

Vaccination against *small-pox* is one of the oldest and perhaps the most successful form of prophylactic immunisation. The antigenic material employed is living vaccina virus. Recent studies have demonstrated quite clearly that vaccinia virus and variola virus are antigenically identical. Vaccination provides a striking example of effective immunisation against a disease that is caused by a single antigenic type of micro-organism.

Enteric fever is a clinical designation for a group of infections caused by the typhoid and paratyphoid bacilli. Since the typhoid bacillus plays a major part in most countries, we should expect the use of an antityphoid vaccine to lead to a significant reduction in the number of enteric infections, and this has proved to be the case. But we should not expect it to prevent infection with the paratyphoid bacilli A, B, and C, and experience in the war showed that it does not. These three types, together with the typhoid bacillus itself, account for the vast majority of enteric infections. In Western Europe the C type is infrequent. By including the A and B types in our vaccine, in addition to the typhoid bacillus, we should expect to obtain a very considerable reduction in the frequency of enteric infection. Experience in the war indicated that this reduction is, in fact, obtained. Enteric fever affords a good example of a disease in which effective immunisation is possible because the causal agents, although they are antigenically different, are few in number.

FIG. 4

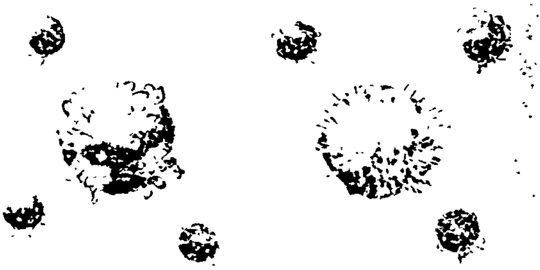


FIG. 5

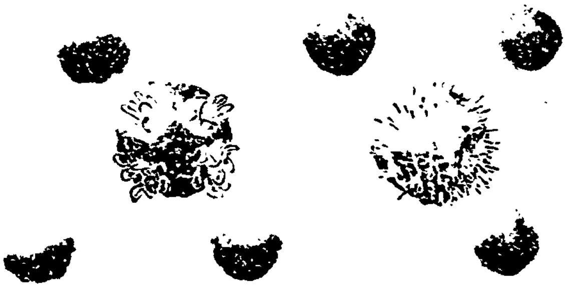

FIG. 6

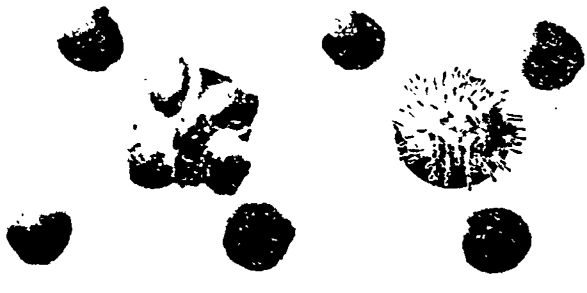

Lobar pneumonia is caused by a wide variety of different antigenic types of pneumococci. The best that we could expect from prophylactic vaccination would be a reduction in frequency commensurate with the elimination of infection due to the types included in our vaccine, and since the types are many and vary in their relative frequency from place to place and from time to time, our expectations would not run high. In fact, the history of prophylactic immunisation against lobar pneumonia has been a chequered and, on the whole, unhappy one. We might take it as an illustration of failure in the face of a multiplicity of antigenic types; but fairness compels the proviso that the records suggest that some part of the failure at least may be due to a relative ineffectiveness of antibacterial immunisation against this disease, even when the immunological requirements are fulfilled.

We have noted already that *diphtheria* affords an excellent example of the effectiveness of antitoxic immunity, unassociated with antibacterial immunity, as a protection against an infection that is almost wholly toxæmic, and that *scarlet fever and allied conditions* illustrate the modifying effects of an antitoxic immunity on infections that are in part toxæmic, in part invasive. We may, perhaps, expand our picture of immunity to hæmolytic streptococci by noting that the clinical records indicate quite clearly that an antitoxic immunity affords no significant protection against such a typically invasive disease as *puerperal septicæmia.*

In general it is true to say that where the basic principles of specific immunisation have been followed a very considerable degree of success has been achieved, and that the failures or partial failures have been encountered where we should have expected to find them. But these basic principles have not always been followed. They are not always followed to-day. The results that are obtained when they are neglected are a most useful control to the results that are obtained when they are observed.

One of the most important of our minor infective diseases is the *common cold.*

Its causation must still be regarded as an unsolved problem, though there is a growing body of evidence in favour of the view that the primary causative agent in the acute infectious type of cold that spreads readily from one person to another is a filtrable virus. This evidence, and many other observations relating to the normal bacterial flora of the nose, throat and nasopharynx, tell strongly against the view that the acute infectious cold is caused by pneumococci, influenza bacilli, hæmolytic streptococci, Gram-negative diplococci, or any of the other potential pathogens that are commonly found in these situations. This does not mean that these bacteria play no part in the total syndrome of the common cold as it frequently develops. They are quite certainly concerned in the suppurative infections of the nasal passages and sinuses that are such common complications. But the pneumococcus, the influenza bacillus, and the hæmolytic streptococcus are all antigenically heterogeneous species. There are at least 32 types of pneumococci, probably as many, if not more, types of hæmolytic streptococci, and an unknown but certainly large number of types of influenza bacilli. There is no evidence that the strains of any one of these three organisms associated, probably as secondary invaders, with the common cold are confined to a few serological types; all the available evidence is to the contrary.

What is the probable result of inoculating a person with a mixed bacterial vaccine containing a few types of pneumococci, some hæmolytic streptococci and influenza bacilli, and perhaps an assortment of other organisms? If, as seems probable, the common cold is a virus disease, then we shall clearly *not protect against the primary infection*. Shall we lessen the frequency of concomitant bacterial infections? It does not seem likely. We know very little in regard to the power of bacterial vaccines to afford protection against antigenically similar organisms when these organisms are acting as local secondary invaders in association with a filtrable virus, and what little we do know is not very hopeful. Even if it were, our expectations would be small; for there is no reason to suppose that the particular pneumococci, influenza bacilli, or hæmolytic streptococci that are present on, or gain access to, the nasopharyngeal mucosa of the vaccinated sufferer from the common cold will be antigenically similar to those included in the vaccine.

In conformity with our expectations, we find that in almost any instance in which a practical trial has been made of this method on an adequate scale and with proper controls it has been a clear and conspicuous failure.

Influenza falls into the same category. It is probably *another virus disease*. When we have obtained the virus in a manageable form—or the viruses if more than one antigenic type is concerned—we shall probably be able to protect successfully against influenza; and when we can do that we shall have conquered one of the major pestilences of our time. But, though the primary cause of influenza be a virus, there can be no doubt at all that the influenza bacillus plays a very important part as a concomitant bacterial invader; sometimes, at least, pneumococci and hæmolytic streptococci may play a similar or accessory rôle. What is the likelihood that a vaccine composed of influenza bacilli, or of influenza bacilli and pneumococci and hæmolytic streptococci, will prevent influenza, or significantly lower the frequency of the associated bacterial infections? The answer is clearly the same as that at which we arrived in regard to the common cold; *and here again large-scale trials, carried out under properly controlled conditions*, have amply confirmed that answer.

The results of experience—the negative as well as the positive ones—thus give us some confidence that, in applying the principles of specific immunity, so far as we know them, to the problems of practical prophylaxis, we are on the right lines. If so the future is not unhopeful. We are still very ignorant. In only a few instances do we yet know which bacterial antigen, of the many that are always present, plays a dominant rôle in the immunising process. Even in these cases we do not know whether other antigens, which alone may be quite ineffective, play a significant accessory part. It is probable that the crude bacterial suspensions we now employ are very imperfect reagents. The problem of improving them is a problem in applied chemistry. When it is solved we may be in a much better position than we are to-day to control those infective diseases that have failed to yield to other methods of preventive medicine.

PANEL AND CONTRACT PRACTICE

INCAPACITY FOR WORK

AT its meeting on May 24th, the Medico-Legal Society discussed the nature of incapacity for work within the meaning of the National Health Insurance Acts. Mr. W. J. FOSTER, assistant secretary to the Prudential Assurance Co., said that under the 1924 Act an insured person was entitled to sickness or disablement benefit if he was rendered incapable of work by some specific disease or by bodily or mental disablement. The Act was not helpful in defining incapacity. The question was begged by talk about incapacity being due to such disease or disablement, but a certain amount of case law had arisen in the form of decisions given by referees appointed by the Ministry of Health. A member of an approved society was bound by the rules of his society; if the interpretation of these rules was disputed he had the right of appeal to the Ministry. The Minister then appointed either a barrister or a solicitor, associated with a medical assessor when expert medical knowledge was required. In the case of a woman appellant the medical assessor must be a woman doctor unless the appellant's own doctor was of her sex.

In the phrase "rendered incapable of work," what, Mr. Foster asked, actually is the meaning of the word "rendered"? Take a man who had had an accident for which he was receiving compensation; subsequently another incapacity supervened in the form of illness. His compensation pay is greater than his sick pay but when payment for compensation ceases can he then be said to be "rendered" incapable by the supervening illness? A decision has been given that a man cannot be "rendered" incapable if at the time of the commencement of the supervening illness he was already incapacitated. Total incapacity was required by the Act. In compensation cases a man may be totally or partially disabled but in health insurance a partial incapacity did not entitle to benefit.

In the old days to excuse a man from attending (say) a jury it had to be proved that he was "in bed with his boots off" and four knights were sent to his house to satisfy the court that this was so; they would report that he was "unbuckled, unbooted and ungirt." This process of proving incapacity was not possible to-day. They had to use common sense in deciding capacity to work. The work was supposed to be remunerative and *suitable to the capacity of the worker. It need not necessarily* be the worker's normal occupation. A miner with rheumatism and lumbago might be quite incapable of ever hewing coal again but able to do some light work. Disablement benefit which follows 26 weeks of sickness benefit must not be regarded as an old age pension. It was necessary to take into account the man's previous training, his aptitude for work, the availability of work—although slackness of work in the labour market could not be taken into account in deciding whether incapacity existed. It was the duty of an insured person to try to make himself capable by training and a decision had been given on this matter in the case of a blind man who was offered training for quite a long period (three or four years) but who by refusing to be trained lost his appeal against the society which had stopped his disablement pay.

After 26 weeks of sickness benefit the question of *alternative employment will come up for consideration*. This may be considered before or it may be taken later, but it is not the duty of the medical man attending the case. Here the society has to use common sense in dealing with individual cases. An illiterate labourer cannot be expected to take up clerical work.

COMPENSATION OR HEALTH INSURANCE

Compensation cases, said Mr. Foster, at times give rise to difficulty under the Act. A judge had defined total incapacity as *the condition of a man in which* a physical defect made his labour unsaleable, and a partial incapacity made his labour sell for less than normal. There was *no parallel under* the N.H.I.

Acts. A charwoman dislocated her shoulder at work. The dislocation was never reduced and although she had no loss of power in the forearm she could not scrub owing to the shoulder trouble. She was found to be partially disabled *qua* compensation but she had to find alternative occupation. In pregnancy the particular circumstances of each case had to be considered. A normal pregnancy might give rise to incapacity but in arriving at a decision no consideration could be given to rules of employers nor to æsthetic appearance. The welfare of the unborn child was irrelevant. The woman's occupation was important. There was the case of a married private secretary who claimed benefit for a normal pregnancy; but she lost. Hardship undoubtedly occurs when women are dismissed from their employment. Often on marriage women give up their normal occupation and take on the ordinary duties of a housewife. Can this be called remunerative occupation? The husband would have to pay someone to do the work if the wife did not do it. This was sometimes disputed but in reply to a recent question in the House of Commons the Minister of Health had agreed that housework could be considered as remunerative work. Difficulty arose where incapacity for a short period was frequent as in asthma, menorrhagia or epilepsy. Such patients cannot keep their work. In cases of epilepsy one has to consider the nature of the fits, their effect on the person and his mentality, but the difficulty of obtaining employment through the possibility of incapacity was not to be considered when deciding capacity to work.

Mr. Foster finally dealt with the subtle distinction made by the House of Lords between incapacity *to* work and incapacity *for* work. A workman with a useless eye whose condition was not noticed sustained an accident to his bad eye so that the condition became apparent through the removal of that eye. It was held that his capacity *to* work was the same as it was before when he had worked with the other eye only, but that his capacity *for* work was now nil because no one would employ him with one eye. He was awarded total compensation. Actually the wording of the N.H.I. Act was incapable "of," a phrasing not quite so wide in its meaning.

THE MEDICAL CRITERION

Dr. R. GODWIN CHASE, a member of the London Insurance Committee, said he thought the chief criterion a medical man had to use in deciding incapacity for work was whether the patient would be harmed by doing that work. Patients might describe terrible pains which they felt about joints in which full movement could be obtained. Practitioners sometimes failed to take into consideration the question of travelling involved in return to work. Pregnancy cases were really difficult; amongst 20,000 certifying doctors each would have his or her own view as to whether a woman should work in the latter stages of pregnancy. Experts were not agreed. Even the Ministry of Health spoke with two voices. While memoranda issued from the health insurance department implied that uncomplicated pregnancy was no bar to work, other memoranda from the infant welfare department advised quite long periods of rest before confinement took place. Patients talked to each other about these certificates and the conscientious doctor might lose patients through acting in the strictly legal manner. Certification in infective diseases was also difficult. A waitress with a septic rash on her face would not be allowed by her employers to work, although she was capable within the meaning of the Act. The same applied to scabies. Patients thought they were harshly treated if a certificate of incapacity was refused; they could, however, be given a letter to say that, whilst they were not incapable within the meaning of the Act, yet it was highly undesirable for them to work owing to the infective condition present.

Dr. W. DUNCAN, senior medical officer, General Practitioner Service, Ministry of Health, said that only a few doctors had any legal training, and it was a marvel to him that so few mistakes were made by the 20,000 doctors in insurance practice. Some of them took the view that their duty was solely to treat the patient and to get him better; they should not be bothered with certificates, that was the approved societies' work. But they would not let laymen decide whether incapacity was present and would not like a strange doctor to visit their cases solely to give certificates. A possible difficulty arose from the attendance required at hospital or clinic at some particular time which might reveal to an employer the fact that an insured person was ill, and in (say) a case of venereal disease might lead to dismissal from work. He thought some societies had funds from which as an additional benefit they could pay for the cases of infective diseases mentioned. Some married women in class K, reading that they were able to have six weeks benefit before they went out of insurance, interpreted that to mean that they were to have it and would approach the doctor with the statement, "I want my six weeks benefit."

A SUGGESTED SOLUTION

Dr. R. E. CROSSE thought it would be better if the medical side could be separated from the administrative side of the work. Doctors would then look after the medical problems, leaving administrators to deal with such difficulties as whether the insured person was entitled to benefit, and the relation of work to environment and availability. The word incapable should not be used in certification and the doctor should simply be asked to say whether a person was fit to work. He would divide patients into three classes: (1) those temporarily unfit for their work, (2) those permanently unfit for their work but not unfit for some other work, (3) those unfit for anything. He had tried to get this adopted some years previously but it was then thought that insured persons in small approved societies would suffer if it were adopted.

Mr. H. LESSER said the Act was administered by approved societies who inherited the old friendly society spirit and worked quite smoothly. Only fine points involving important principles were decided by referees. For example, a society was able to show that a blind man in receipt of disablement benefit received betting slips for a bookmaker in a public house, being taken there by a small boy. They could not prove he was paid for this but they said it was normally a remunerative occupation and on appeal the society won, thus establishing the principle of no benefit if working. It was always difficult to say at what point in pregnancy work should cease. The scope of a society's ability to pay was determined by a financial contract. It had been stated that one day's extra pay to everybody would mean complete financial breakdown of the Act. An insured person might be unfit but not incapable. To decide whether convalescent treatment should be given it was not a question whether it was beneficial but whether a stay at a convalescent home was necessary to recovery. Doctors and societies must interpret their legal obligation on common sense grounds except where there was serious suspicion of malingering. A huge proportion of insured persons were declared fit on

Saturday to resume work on Monday; was this the advice which the doctor gave to the patient or was it the patient who was then advising the doctor?

Dr. A. Baldie thought that, whilst the average doctor was not a lawyer, in his own sphere he was very efficient. He was not allowed to alter the form of certificate and at times he must include people who were not really incapable. If the Act had been unable to stand the strain of the last nine years its actuarial basis must be wrong; but the doctors were blamed for it. Alteration in regulation and in the forms of certificates would enable insurance doctors to do their work properly and render the Act more popular.

Mr. Foster, in reply, pointed out that work was often quite beneficial to neurasthenic people. Doctors were "debarred" from giving certificates of incapacity in uncomplicated cases of pregnancy; he thought that was going rather far. The infective cases were very difficult. Additional benefit could be paid to an insured person because his relatives were ill with infection but not because the patient himself was infective, if not incapable. He did not think the alteration of certificate would help much, for the doctor would have to decide the category in which to put the patient and again references to the R.M.O. would still be necessary.

Novarsenobillon

The Birmingham insurance committee reports that the Minister has decided not to refer to referees the question whether the intravenous injection of novarsenobillon falls within the terms of those extra services outside the Act for which an insurance practitioner (with special qualifications to perform such services) may make a charge to the patient. This decision is in conformity with that of the local medical committee and of the insurance committee, both of which had agreed that this service was outside the Act. It is possible that the toxicity of the medicament rather than the degree of manipulative dexterity required has determined the decision, for the injection of varicose veins has been definitely held to be within the scope of the Act.

THE SERVICES

IMPROVED CONDITIONS FOR THE ROYAL AIR FORCE MEDICAL SERVICE

New regulations have now been issued embodying the recommendations of the Warren Fisher report. To lessen the strain of orderly duty and so increase the number of candidates for temporary commissions in the R.A.F.M.S. that orderly duty is to be reduced. Within five years about half of the short-service officers will be enabled to get permanent commissions. Those leaving for the reserve in three years will get a gratuity of £400 (£50 increase), increased after five years' service to £1000 (£300 increase). Permanent officers not qualified for retired pay and allowed to retire between five and ten years will get £1000 gratuity, after ten years £1500, and after 15 years £2800 (£300 increase). Promotion will be accelerated and increased throughout: pay of squadron leaders will be increased by 5*s.* daily, but without the present increase after eight years (when presumably they will have won their promotion); wing commanders and below can serve up to the age of 55, an extension of four years. Specialist pay is not now given as such to specialists, but in future they may win accelerated promotion (up to two years) to squadron leader. These changes offer definite prospect of better incomes to R.A.F. officers in future.

COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS

The War Office announces that applications are invited from medical men for appointment to commissions in the Royal Army Medical Corps under the new conditions announced recently. Candidates will be selected for commissions without competitive examination and will be required to present themselves in London for interview and physical examination on or about June 6th. They must be registered under the Medical Acts and normally must not be over the age of 28 years. Successful candidates will in the first instance be given short service commissions for five years, at the end of which period they may either retire with a gratuity of £1000 or apply for a permanent commission. Permanent commissions will be given to officers selected from among those who wish to make the army their permanent career.

Full particulars on application, either by letter or in person, to the assistant director-general, Army Medical Services, The War Office, London, S.W. 1.

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt.-Comdrs. A. E. Phillips and G. Kirker to be Surg. Comdrs.

Surg. Lts. W. W. Beach, A. R. Ewart, and R. Russell to be Surg. Lt.-Comdrs.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. (D) D. C. Lamond is placed on the retd. list.

Surg. Sub-Lt. K. W. Martin to be Surg. Lt.

The following appointments are notified: Surg. Lt.-Comdrs. C. C. Ungley to *Tiverton*, R. L. Stubbs to *Valiant*, and F. A. McLaughlin to *Malaya*.

Surg. Lt. G. M. Tanner to *Tiverton*.

ROYAL ARMY MEDICAL CORPS

Lts. J. E. Snow, N. H. Lindsay, C. S. Gross, W. R. M. Drew, and A. Macdonald to be Capts.

ARMY RESERVE OF OFFICERS

Lt.-Col. P. J. Marett having attained the age limit of liability to recall ceases to belong to the Res. of Off.

TERRITORIAL ARMY

Col. C. R. White, retd. T.A., vacates the appt. of Hon. Col. R.A.M.C. Units, 53rd (Welsh) Div., on completion of tenure.

Col. C. L. Isaac, retd. T.A., to be Hon. Col. R.A.M.C. Units, 53rd (Welsh) Div.

Maj. C. Helm (Lt.-Col. Res. of Off.), resigns his commn. in the T.A.

Lts. W. E. Underwood and W. E. Orchard to be Capts.

E. F. S. Morrison (late Cadet, Epsom Coll. Contgt., Jun. Div., O.T.C.), to be Lt.

J. A. Blain (late Cadet, St. Andrews Univ. Contgt., Sen. Div., O.T.C.), to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. W. H. A. Dodd resigns his commn.

Lt. H. R. Vernon, from Active List, to be Lt.

INDIAN MEDICAL SERVICE

Col. G. C. L. Kerans retires.

Majs. R. Hay, W. P. Hogg, and H. E. Murray to be Lt.-Cols.

Capt. J. S. B. Forde relinquishes his proby. appt.

ROYAL AIR FORCE

Flight Lt. J. Parry-Evans is promoted to the rank of Squadron Leader.

The undermentioned Flying Offrs. are promoted to the rank of Flight Lts.: J. McGovern, J. F. Dales, T. D. L. Bolan, and R. E. W. Fisher.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS.

In opening the 139th session of the Council, on May 29th, the President, Sir Norman Walker, after mentioning that the composition of the Council was the same as at the previous session, made graceful allusion to three one-time members who had died in the interval. Of Sir William Whitla, a member of the Council from 1910 to 1916, he said that his work on the Pharmacopœia Committee was extremely valuable, while of A. G. Barrs, who was a member of the Council from 1904 to 1918, he said that on the same committee a deep knowledge of therapeutics had been wisely employed. Of the third deceased member, Sir Donald MacAlister, he recorded the remarkable fact that his tenure of office had lasted 43 years, during 27 of which he had been President. After alluding to the many instances in the proceedings of the Council where MacAlister had given evidence of familiarity with every facet of the work, and to the practical employment to which his linguistic scholarship had been put, he pointed to his remarkable capacity as "a Moderator, as he would have been called in the Scottish Ecclesiastical Courts;" for only short and pertinent talking was encouraged by him, while throughout his whole term of office only in six years was a deficit displayed in the balance sheet of the Council; one such deficit was £7 8s., while before Sir Donald's time annual deficits would average £1000. Sir Norman continued:—

"The accounts for the year 1933 have been duly audited and presented to Parliament. They show a surplus of income over expenditure for the year of £564 7*s.* 4*d.*, a surplus not so large as that of last year, but still satisfactory. I shall not trespass on the province of the treasurers by referring to any details.

In 1933 the names of 1343 practitioners were added to the Medical Register, being two less than in 1932. But the losses were 150 less, and so the Register on Jan. 1st, 1934, contained 56,741 names, the largest number ever reached. The Student's Register showed an increase of 340 names, 272 in England, 38 in Ireland, while Scotland stands just where it did last year. The Education and Examination Committees will doubltess take note of these figures.

MEDICAL EDUCATION

The General Council for Medical Education and Registration has as its main object the first of these subjects. The Education Committee was set up by the Council in 1859, and down the years successive education committees have submitted valuable reports, many of them still well worth study. Medical education and its bearing on the public weal is to-day the subject of anxious consideration in every civilised country. In the United States there have been far-reaching inquiries into medical practice and its many relations to the public, and a realisation that, as times change, it may be that education must change with them. Sir Henry Acland, through whose scholarly addresses I often go gleaning, said in 1887 "that the Council had received whatever aid can be derived from abundant criticism, which would have had more real value had it fully appreciated the difficulties of a period of progress never equalled." It is doubtful if there had been, in the years prior to 1887, so great and so rapid changes as there have been in the last 20 years. The boundaries of medicine are ever extending, and there is more and more to be learned. The Council welcome all the inquiries which are going on as likely to contribute to the solution of a difficult problem. But it is right here to make clear the position of the Council. It is not possible to frame a model curriculum which will suit every country or every school in any country, and no hard-and-fast arrangement of subjects is possible, even if it were desirable.

In this connexion, the Royal Commission of 1882, on whose report the 1886 Act is based, said: "It would be a mistake to introduce absolute uniformity into medical education. One great merit of the present system, so far as teaching is concerned, lies in the elasticity which is produced by the variety and number of educational bodies. Being anxious not to diminish in any way the interest which the teaching bodies now take in medical education, or to lessen their responsibility in that respect, we desire to leave them as much initiative as possible. In certain matters of general importance, such as the duration of study, and the age at which a student should be permitted to practise, common regulations ought, we think, to be laid down; but we wish to record our opinion that nothing should be done to weaken the individuality of the universities and corporations, or to check emulation between the leading institutions of the country." This policy has been followed by the General Medical Council, whose primary concern is with the qualifications for admission to the Medical Register. These are the words of the 1886 Act: "The standard of proficiency required from candidates at the said qualifying examination shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery, and it shall be the duty of the General Medical Council to secure the maintenance of such standard of proficiency as aforesaid." Each licensing body is free to try out new methods, and those which are found successful are likely to be imitated and perhaps improved on by others. I do not think it is sufficiently realised in other countries how much we gain from our unique system of external examiners; this meeting of teachers from different schools is perhaps the most efficient way of diffusing information. The Education Committee have been hard at work since last we met; their report, which was yet in its final form this forenoon, will be in your hands, I hope, to-morrow, and it is proposed to set aside Friday forenoon for its discussion.

THE PHARMACOPŒIA COMMISSION

The Pharmacopœia Committee will pass on to us the report of this Commission, which shows that that body have been diligently engaged in preparing the ground for the next Pharmacopœia, and the laboratory provided in this building has been very useful in connexion with their researches.

PROGRESS IN HONG KONG, SINGAPORE, AND CEYLON

The executive committee has considered reports by Sir Richard Needham on Hong Kong and Singapore. These show how useful it is to these far-away schools to have a visitor from this country with a full knowledge of the conditions of medical education in this country, and both Hong Kong and Singapore are grateful for the help they have received from our visitor. Sir Richard at Ceylon revisited the Medical College, and reports that many of the improvements whether the disease is increasing or diminishing in Great Britain; the widespread neglect of adequate precautions against its increase makes any diminution improbable. No cure for tuberculosis is known. Immunisation with B C G may soon approach a stage of practical usefulness, but to-day is not an important outwork in the farmers' defence. The eradication of bovine tuberculosis in cattle would lead to its disappearance in swine as well as in horses, goats, and cats. The scheme proposed for the eradication of bovine tuberculosis recommended by the Committee should in its opinion provide for:—

(1) The institution of a list of tuberculosis-free herds (accepted herds), tested with tuberculin from time to time under official supervision, and declared to be free from bovine tuberculosis.

(2) The provision of free advice and free tuberculin-testing for owners of herds who agree to make bona-fide efforts to free their herds from tuberculosis, or who have established free herds.

(3) Financial help, where necessary, by way of loans or the guarantee of loans, to approved owners for the purpose of undertaking expenditure required by the veterinary inspector as necessary to eradication.

(4) The securing to owners of disease-free herds of a higher price for their milk than that obtained by other owners.

(5) The taking of administrative measures designed to secure that tuberculosis-free cattle from accepted herds should be moved about the country and exposed for sale without running the risk of being brought in contact with other cattle.

(6) The adjustment of regulations governing the production of graded milks and the grades of milk officially approved, and the making of regulations relative to the compulsory pasteurisation of milk with a view to increasing the incentive to farmers to eradicate tuberculosis from their herds.

As far as human health is concerned bovine tuberculosis is regarded as the only material danger from milk. Contagious abortion may be responsible for serious loss to dairy farmers, both directly and indirectly by causing sterility, even if the suggested 40 per cent. prevalence is not grounded upon adequate statistical investigation. Undulant fever, its counterpart in man, is, however, rare in this country and would still be unimportant even were its incidence as high as in Germany. The real protection of the public from this fever, the report remarks, is their own immunity. About the importance of milk in the spreading of other infectious diseases the available evidence is regarded as inconclusive. Such milk-borne infections however have one peculiarity—the organisms responsible for them multiply rapidly in milk; the pooling of milk consequently adds enormously to the chances of infection.

The only remedy, even tolerably complete, for the condition into which our dairy industry has been allowed to fall is the complete eradication of bovine tuberculosis from the herds. The limiting conditions of such action at the outset are the lack of trained veterinary staff and the shortage of healthy cows available to replace those infected. The uncoördinated initiative of individual farmers under the stimulus of higher prices for pure milk at a rather distant future will not of itself create the necessary conditions for any general advance. For this reason it is essential that the Ministry of Agriculture should take an active hand in planning and subsequently in directing the campaign for eradication, especially in its early stages.

The Grading of Milk

The Committee considers that all milk sold for consumption in liquid form should be required to be sold under an official designation. The designation of the milk should be clearly marked on the vessel in which it is sold to the public, a distinctive colour being prescribed for marking each designated milk. No liquid milk should be sold that does not attain a fixed standard of cleanliness, or pre-pasteurisation standard, at the farm. This standard should approximate to that at present required for Grade A milk. In addition, all milk should conform to the definitions of one of the following designations:

(1) *Certified milk*—namely, milk which has not undergone any process of heat-treatment and is derived from tubercle-free herds. This milk should not be required to be bottled on the farm.

(2) *Pasteurised milk*—namely, milk which has undergone, once only, a process of heat-treatment approved for this purpose by the Ministry of Health or the Department of Health for Scotland, and has undergone no other process of heat-treatment. Pasteurisation should be permitted only in a plant licensed for the purpose.

(3) *Sterilised milk*—namely, milk which has been raised to the boiling-point or higher in a plant licensed for the purpose, and which has undergone no other process of heat-treatment.

(4) *Milk (uncertified)*—namely, milk which has undergone no form of heat-treatment and is not derived from tuberculosis-free herds, but which attains a certain hygienic standard.

No milk which has been held in any vessel containing more than 100 gallons of milk, unless derived from a single herd, should be sold for consumption in liquid form unless it has subsequently been pasteurised.

The council of any county borough, municipal borough, large burgh, or urban district in an area the population of which exceeds 100,000, and the London County Council should have the right to prohibit the sale of milk (uncertified) as defined above after a date which shall not be earlier than five years after the initiation of the scheme of eradication, provided that it has given not less than two years' notice of its intention to do so.

Pasteurisation

The pasteurisation of milk to be sold under the order should only be permitted in plants the design of which has been officially approved, which have themselves been tested on erection to ensure that they conform to the approved design, and which are frequently inspected during working by an officer of the sanitary authority, who should apply prescribed tests and record the results at each visit. The authority responsible for approving the design of plants should act only after consulting the National Physical Laboratory.

It is emphasised that pasteurisation cannot make dirty milk clean and, therefore, would not discourage farmers from producing clean milk. If correctly introduced, it would encourage them to undertake eradication. On the other hand, the compulsory pasteurisation of milk would disturb the balance at present existing in large towns between the producers of milk in comparatively distant areas for sale after heat-treatment, and the producers of milk in the immediate neighbourhood of large towns for sale in a raw state. Pasteurisation is incompatible with the business methods of producer-retailers and, if it were made compulsory at once, a large number of them would be deprived of their present livelihood.

No policy at the outset satisfies both the interests of public health and those of producer-retailers near large towns. Clinical inspection is not a satisfactory alternative to pasteurisation in those areas where the latter is practicable, nor could producer-retailers make their milk safe by the eradication of tuberculosis until this has made considerable progress in the breeding areas. But, as soon as a sufficient supply of clean cows can be created to enable producer-retailers to free their herds from tuberculosis, it will be fair to make them choose between doing so and submitting to pasteurisation.

IRELAND

(FROM OUR OWN CORRESPONDENT)

BOVINE TUBERCULOSIS AND MILK

In the Dáil last week Mr. S. T. O'Kelly, Minister for Local Government and Public Health, gave assurances that he would soon be ready to introduce the long-promised Bill to deal with the milk-supply. He did not pledge himself that it could be brought in during the present session, but he stated that his advisers had been busy with it, and had now overcome the difficulties that had previously stood in their way. The history of this measure is interesting. Early in 1928 the report of an Inter-Departmental Committee on the Milk Supply was presented, and the then Minister promised early legislation to carry the recommendations into effect. Some fifteen months later he outlined his proposed legislation to the Dáil, but nothing more was heard of the Bill. The present Minister took up office early in 1932 and in autumn of that year declared his intention of bringing in a Milk Bill. Until his announcement last week he had not reverted to the subject. The proposal to impose conditions on the production and distribution of milk is unpopular with the farmers, and the Minister must make up his mind to meet plenty of opposition both within and without his own party, for the agricultural interest is strong in the Dáil. The present moment, however, offers an exceptional opportunity for dealing radically with the problem of tuberculosis in cattle if the Government has the determination to seize it. Never in history has the price of stock been so low, and if the Government were to decide to destroy all tuberculous strains in cattle it could be done at relatively small expense. The Minister for Agriculture, indeed, threw out a hint some weeks ago that his mind was running in this direction. He has stated definitely more than once that the number of cattle in the country was more than its needs required, and he suggested that in reducing the surplus attention should be paid to the destruction of tuberculous stock.

MEDICINE AND THE LAW

Cheese, Natural or Synthetic

To the question "what is cheese?" the Food and Drugs (Adulteration) Act replies that it is "the substance usually known as cheese"—a conclusion which would perhaps have been reached by magistrates without statutory aid. The definition does, however, go on to stipulate that the substance must contain no fat derived otherwise than from milk. This stipulation was vital in a recent prosecution by the Islington borough council in a case where a public-house licensee had sold as a cheese sandwich a substance containing 41 per cent. of fat other than milk fat. The additional ingredient was stated to be beef fat. The addition brought the cheese sandwich within the statutory definition of "margarine cheese"—i.e., "any substance whether compound or otherwise which is prepared in imitation of cheese and which contains fat not derived from milk." The defendant in the Islington case explained that real cheese would go mouldy. The magistrate held that the purchaser of one of these cheese sandwiches would expect to buy a sandwich composed of biscuit and real cheese; purchasers were not getting an article of the nature, substance, and quality demanded. In view presumably of the absence of any sinister feature in what was a test case, the magistrate did not record a conviction but merely dismissed the summons on payment of two guineas costs. Future defendants in similar circumstances will perhaps escape less lightly.

In discussing lately the report of the departmental committee on food standards (THE LANCET, May 19th, p. 1076), it was mentioned that the purchaser of cheese gets articles with varying proportions of fat for which no statutory limit is prescribed. Statutory percentages are somewhat complicated to enforce, though the Sale of Milk Regulations have for a long time fixed a certain minimum of milk fat below which the milk is prima facie deemed not genuine by reason of the abstraction therefrom of milk fat or the addition thereto of water. A more ambitious effort is made by the standard set up under the Agricultural Produce (Grading and Marking) Act for Cheshire cheese; here there is a general requirement that the cheese shall be made from full-cream cow's milk "and shall contain a minimum of 45 per cent. of butter fat in the moisture-free substance." For the purpose of the Food and Drugs (Adulteration) Act there is no such standard. The recent departmental committee heard evidence specifically about cheese, but refrained from any recommendation. In effect, therefore, the producer and seller of cheese can take the fat out of the article so long as they put no other fat in.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 19TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 4 (last week 3); scarlet fever, 2428; diphtheria, 1197; enteric fever, 21; acute pneumonia (primary or influenzal), 989; puerperal fever, 33; puerperal pyrexia, 116; cerebro-spinal fever, 36; acute poliomyelitis, 3; encephalitis lethargica, 14; dysentery, 7; ophthalmia neonatorum, 86. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 28th–29th was as follows: Small-pox, 9 under treatment, 0 under observation (last week 14 and 0 respectively); scarlet fever, 1622; diphtheria, 1698; measles, 2363 (last week 2493); whooping-cough, 302; puerperal fever, 32 mothers (plus 11 babies); encephalitis lethargica, 258; poliomyelitis, 2; "other diseases," 125. At St. Margaret's Hospital there were 18 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 55 (18) from measles, 8 (0) from scarlet fever, 38 (7) from whooping-cough, 47 (11) from diphtheria, 43 (13) from diarrhœa and enteritis under two years, and 33 (2) from influenza. The figures in parentheses are those for London itself.

Liverpool and Newcastle-on-Tyne each reported 5 fatal cases of measles, West Ham 3, no other great town more than 2. Liverpool also reported 8 deaths from whooping-cough, Sheffield and Birmingham each 3. Diphtheria proved fatal in 5 cases at Manchester, 3 at Liverpool.

The number of stillbirths notified during the week was 289 (corresponding to a rate of 43 per 1000 total births), including 45 in London.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual banquet of this society will be held at the Trocadero Restaurant, Shaftesbury-avenue, London, W., on Wednesday, July 4th, at 7.30 for 8 P.M. The hon. secretary may be addressed at 19, Queen Anne-street, W.1.

whether the disease is increasing or diminishing in Great Britain; the widespread neglect of adequate precautions against its increase makes any diminution improbable. No cure for tuberculosis is known. Immunisation with B C G may soon approach a stage of practical usefulness, but to-day is not an important outwork in the farmers' defence. The eradication of bovine tuberculosis in cattle would lead to its disappearance in swine as well as in horses, goats, and cats. The scheme proposed for the eradication of bovine tuberculosis recommended by the Committee should in its opinion provide for:—

(1) The institution of a list of tuberculosis-free herds (accepted herds), tested with tuberculin from time to time under official supervision, and declared to be free from bovine tuberculosis.

(2) The provision of free advice and free tuberculin-testing for owners of herds who agree to make bona-fide efforts to free their herds from tuberculosis, or who have established free herds.

(3) Financial help, where necessary, by way of loans or the guarantee of loans, to approved owners for the purpose of undertaking expenditure required by the veterinary inspector as necessary to eradication.

(4) The securing to owners of disease-free herds of a higher price for their milk than that obtained by other owners.

(5) The taking of administrative measures designed to secure that tuberculosis-free cattle from accepted herds should be moved about the country and exposed for sale without running the risk of being brought in contact with other cattle.

(6) The adjustment of regulations governing the production of graded milks and the grades of milk officially approved, and the making of regulations relative to the compulsory pasteurisation of milk with a view to increasing the incentive to farmers to eradicate tuberculosis from their herds.

As far as human health is concerned bovine tuberculosis is regarded as the only material danger from milk. Contagious abortion may be responsible for serious loss to dairy farmers, both directly and indirectly by causing sterility, even if the suggested 40 per cent. prevalence is not grounded upon adequate statistical investigation. Undulant fever, its counterpart in man, is, however, rare in this country and would still be unimportant even were its incidence as high as in Germany. The real protection of the public from this fever, the report remarks, is their own immunity. About the importance of milk in the spreading of other infectious diseases the available evidence is regarded as inconclusive. Such milk-borne infections however have one peculiarity—the organisms responsible for them multiply rapidly in milk; the pooling of milk consequently adds enormously to the chances of infection.

The only remedy, even tolerably complete, for the condition into which our dairy industry has been allowed to fall is the complete eradication of bovine tuberculosis from the herds. The limiting conditions of such action at the outset are the lack of trained veterinary staff and the shortage of healthy cows available to replace those infected. The uncoördinated initiative of individual farmers under the stimulus of higher prices for pure milk at a rather distant future will not of itself create the necessary conditions for any general advance. For this reason it is essential that the Ministry of Agriculture should take an active hand in planning and subsequently in directing the campaign for eradication, especially in its early stages.

The Grading of Milk

The Committee considers that all milk sold for consumption in liquid form should be required to be sold under an official designation. The designation of the milk should be clearly marked on the vessel in which it is sold to the public, a distinctive colour being prescribed for marking each designated milk. No liquid milk should be sold that does not attain a fixed standard of cleanliness, or pre-pasteurisation standard, at the farm. This standard should approximate to that at present required for Grade A milk. In addition, all milk should conform to the definitions of one of the following designations:

(1) *Certified milk*—namely, milk which has not undergone any process of heat-treatment and is derived from tubercle-free herds. This milk should not be required to be bottled on the farm.

(2) *Pasteurised milk*—namely, milk which has undergone, once only, a process of heat-treatment approved for this purpose by the Ministry of Health or the Department of Health for Scotland, and has undergone no other process of heat-treatment. Pasteurisation should be permitted only in a plant licensed for the purpose.

(3) *Sterilised milk*—namely, milk which has been raised to the boiling-point or higher in a plant licensed for the purpose, and which has undergone no other process of heat-treatment.

(4) *Milk (uncertified)*—namely, milk which has undergone no form of heat-treatment and is not derived from tuberculosis-free herds, but which attains a certain hygienic standard.

No milk which has been held in any vessel containing more than 100 gallons of milk, unless derived from a single herd, should be sold for consumption in liquid form unless it has subsequently been pasteurised.

The council of any county borough, municipal borough, large burgh, or urban district in an area the population of which exceeds 100,000, and the London County Council should have the right to prohibit the sale of milk (uncertified) as defined above after a date which shall not be earlier than five years after the initiation of the scheme of eradication, provided that it has given not less than two years' notice of its intention to do so.

Pasteurisation

The pasteurisation of milk to be sold under the order should only be permitted in plants the design of which has been officially approved, which have themselves been tested on erection to ensure that they conform to the approved design, and which are frequently inspected during working by an officer of the sanitary authority, who should apply prescribed tests and record the results at each visit. The authority responsible for approving the design of plants should act only after consulting the National Physical Laboratory.

It is emphasised that pasteurisation cannot make dirty milk clean and, therefore, would not discourage farmers from producing clean milk. If correctly introduced, it would encourage them to undertake eradication. On the other hand, the compulsory pasteurisation of milk would disturb the balance at present existing in large towns between the producers of milk in comparatively distant areas for sale after heat-treatment, and the producers of milk in the immediate neighbourhood of large towns for sale in a raw state. Pasteurisation is incompatible with the business methods of producer-retailers and, if it were made compulsory at once, a large number of them would be deprived of their present livelihood.

No policy at the outset satisfies both the interests of public health and those of producer-retailers near large towns. Clinical inspection is not a satisfactory alternative to pasteurisation in those areas where the latter is practicable, nor could producer-retailers make their milk safe by the eradication of tuberculosis until this has made considerable progress in the breeding areas. But, as soon as a sufficient supply of clean cows can be created to enable producer-retailers to free their herds from tuberculosis, it will be fair to make them choose between doing so and submitting to pasteurisation.

IRELAND

(FROM OUR OWN CORRESPONDENT)

BOVINE TUBERCULOSIS AND MILK

IN the Dáil last week Mr. S. T. O'Kelly, Minister for Local Government and Public Health, gave assurances that he would soon be ready to introduce the long-promised Bill to deal with the milk-supply. He did not pledge himself that it could be brought in during the present session, but he stated that his advisers had been busy with it, and had now overcome the difficulties that had previously stood in their way. The history of this measure is interesting. Early in 1928 the report of an Inter-Departmental Committee on the Milk Supply was presented, and the then Minister promised early legislation to carry the recommendations into effect. Some fifteen months later he outlined his proposed legislation to the Dáil, but nothing more was heard of the Bill. The present Minister took up office early in 1932 and in autumn of that year declared his intention of bringing in a Milk Bill. Until his announcement last week he had not reverted to the subject. The proposal to impose conditions on the production and distribution of milk is unpopular with the farmers, and the Minister must make up his mind to meet plenty of opposition both within and without his own party, for the agricultural interest is strong in the Dáil. The present moment, however, offers an exceptional opportunity for dealing radically with the problem of tuberculosis in cattle if the Government has the determination to seize it. Never in history has the price of stock been so low, and if the Government were to decide to destroy all tuberculous strains in cattle it could be done at relatively small expense. The Minister for Agriculture, indeed, threw out a hint some weeks ago that his mind was running in this direction. He has stated definitely more than once that the number of cattle in the country was more than its needs required, and he suggested that in reducing the surplus attention should be paid to the destruction of tuberculous stock.

MEDICINE AND THE LAW

Cheese, Natural or Synthetic

To the question "what is cheese?" the Food and Drugs (Adulteration) Act replies that it is "the substance usually known as cheese"—a conclusion which would perhaps have been reached by magistrates without statutory aid. The definition does, however, go on to stipulate that the substance must contain no fat derived otherwise than from milk. This stipulation was vital in a recent prosecution by the Islington borough council in a case where a public-house licensee had sold as a cheese sandwich a substance containing 41 per cent. of fat other than milk fat. The additional ingredient was stated to be beef fat. The addition brought the cheese sandwich within the statutory definition of "margarine cheese"—i.e., "any substance whether compound or otherwise which is prepared in imitation of cheese and which contains fat not derived from milk." The defendant in the Islington case explained that real cheese would go mouldy. The magistrate held that the purchaser of one of these cheese sandwiches would expect to buy a sandwich composed of biscuit and real cheese; purchasers were not getting an article of the nature, substance, and quality demanded. In view presumably of the absence of any sinister feature in what was a test case, the magistrate did not record a conviction but merely dismissed the summons on payment of two guineas costs. Future defendants in similar circumstances will perhaps escape less lightly.

In discussing lately the report of the departmental committee on food standards (THE LANCET, May 19th, p. 1076), it was mentioned that the purchaser of cheese gets articles with varying proportions of fat for which no statutory limit is prescribed. Statutory percentages are somewhat complicated to enforce, though the Sale of Milk Regulations have for a long time fixed a certain minimum of milk fat below which the milk is prima facie deemed not genuine by reason of the abstraction therefrom of milk fat or the addition thereto of water. A more ambitious effort is made by the standard set up under the Agricultural Produce (Grading and Marking) Act for Cheshire cheese; here there is a general requirement that the cheese shall be made from full-cream cow's milk "and shall contain a minimum of 45 per cent. of butter fat in the moisture-free substance." For the purpose of the Food and Drugs (Adulteration) Act there is no such standard. The recent departmental committee heard evidence specifically about cheese, but refrained from any recommendation. In effect, therefore, the producer and seller of cheese can take the fat out of the article so long as they put no other fat in.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 19TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 4 (last week 3); scarlet fever, 2428; diphtheria, 1197; enteric fever, 21; acute pneumonia (primary or influenzal), 989; puerperal fever, 33; puerperal pyrexia, 116; cerebro-spinal fever, 36; acute poliomyelitis, 3; encephalitis lethargica, 14; dysentery, 7; ophthalmia neonatorum, 86. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 28th–29th was as follows: Small-pox, 9 under treatment, 0 under observation (last week 14 and 0 respectively); scarlet fever, 1622; diphtheria, 1698; measles, 2363 (last week 2493); whooping-cough, 302; puerperal fever, 32 mothers (plus 11 babies); encephalitis lethargica, 258; poliomyelitis, 2; "other diseases," 125. At St. Margaret's Hospital there were 18 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 55 (18) from measles, 8 (0) from scarlet fever, 38 (7) from whooping-cough, 47 (11) from diphtheria, 43 (13) from diarrhœa and enteritis under two years, and 33 (2) from influenza. The figures in parentheses are those for London itself.

Liverpool and Newcastle-on-Tyne each reported 5 fatal cases of measles, West Ham 3, no other great town more than 2. Liverpool also reported 8 deaths from whooping-cough, Sheffield and Birmingham each 3. Diphtheria proved fatal in 5 cases at Manchester, 3 at Liverpool.

The number of stillbirths notified during the week was 289 (corresponding to a rate of 43 per 1000 total births), including 45 in London.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual banquet of this society will be held at the Trocadero Restaurant, Shaftesbury-avenue, London, W., on Wednesday, July 4th, at 7.30 for 8 P.M. The hon. secretary may be addressed at 19, Queen Anne-street, W.1.

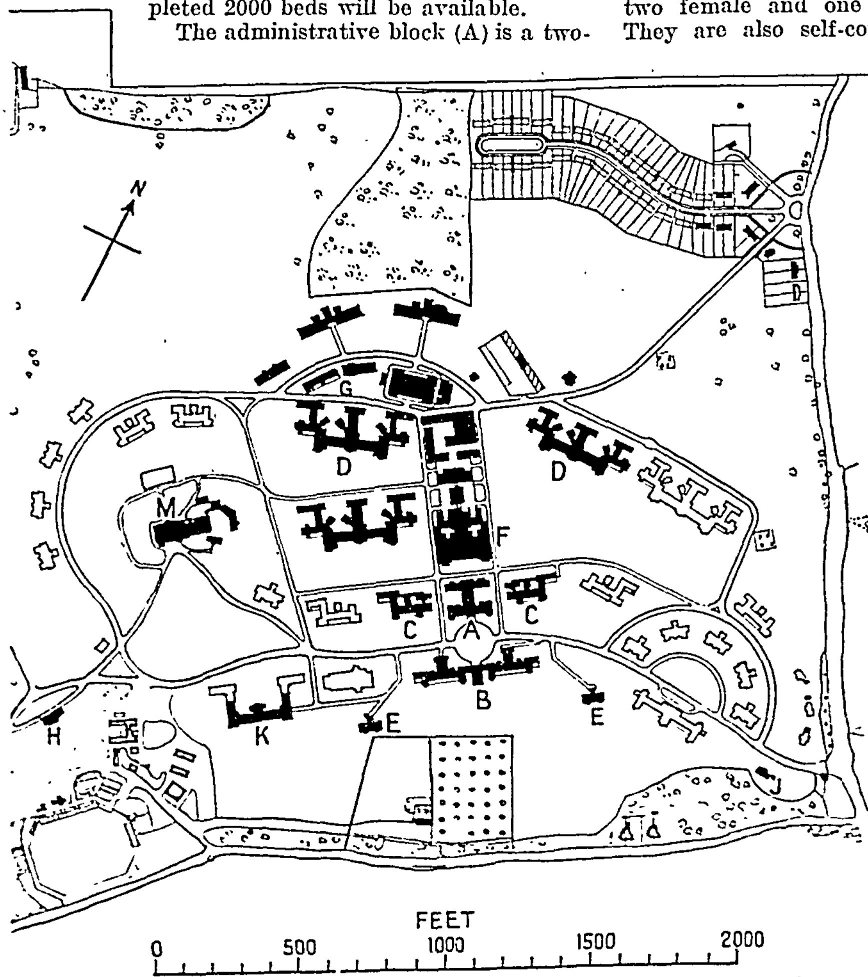
SHENLEY MENTAL HOSPITAL

THE new Middlesex mental hospital at Shenley, near St. Albans, was opened by H.M. The King on Thursday last. The need of more accommodation for mental cases in the northern part of Greater London was brought home to the county authority as long ago as 1911. In 1924 the Porters Park Estate, including a large mansion, the property of Mr. Raphael, came into the market and was bought by the Middlesex county council for £80,000. Besides the mansion and its accessories there are two farms, some cottage property, and a large area of woodland and arable land, totalling just over 1166 acres. The council selected 500 acres of this to found the new hospital, situated for the most part on a ridge 420 ft. above sea level, with an extensive view over Hertfordshire to north and south. Building was commenced in 1932 to the plans of the county architect, Mr. W. T. Curtis, F.R.I.B.A., the contractors being John Laing and Son, Ltd., of Mill Hill. In July, 1932, the foundation-stone was laid by Sir William Lobjoit, chairman of the mental hospitals committee. The hospital is planned on the villa system with small nursing units ranging from 20 to 45 patients. The first section of the building scheme now completed has beds for 1047 patients and about 500 staff. Some 500 patients were admitted during January. When the hospital is completed 2000 beds will be available.

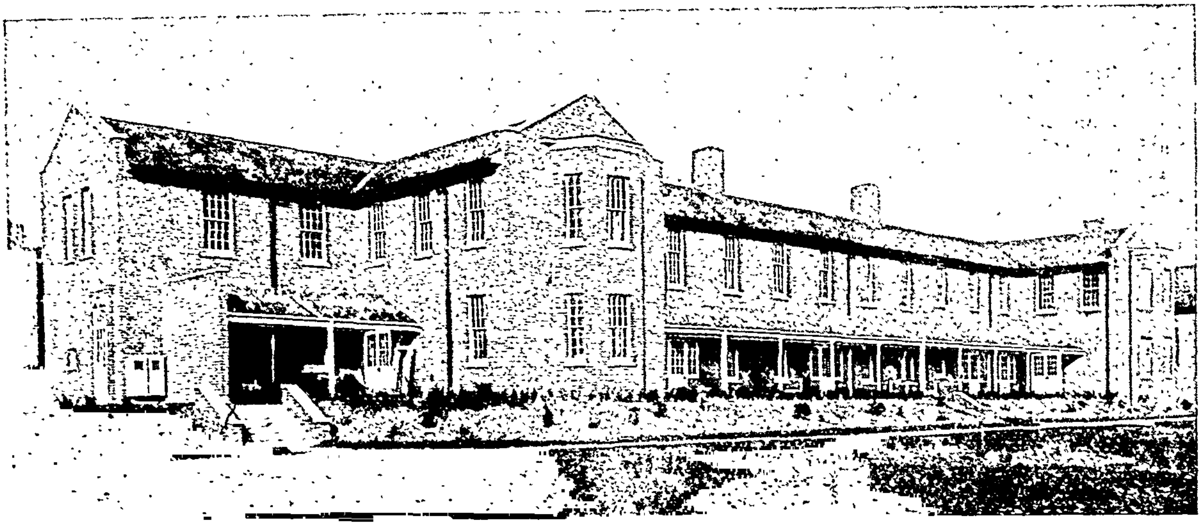
The administrative block (A) is a two-storey building, being approximately in the centre of the colony; on either side of it are the separate villas and hospitals for male and female patients; behind are the recreation hall, kitchen, laundry, and stores. In the central building are the usual offices and committee rooms below, and above the flats for the resident doctors. The laboratories, operating theatre, dispensary, and dental room on the north side are all admirably equipped. The dental chair and apparatus are of modern English make, with electric control; mirrors and instruments are attached to cords which spring back into sockets when released. As there is no supply of gas to the colony in general a small petrol engine has been installed to supply the bunsen burners and other open flames required in the laboratory work.

The reception hospital (B) to the south of this block will house 40 patients of either sex; the doctors' offices and examination rooms lie round the centre hall, the wards and several private rooms to east and west. As throughout the colony where patients are concerned this block faces south. Every patient is admitted to this building and moved as soon as possible after a mental and physical examination to a suitable department. The hospital blocks proper (C) are self-contained nursing units on the ground and first floors. There is a large south verandah where beds can be wheeled outside without any difficulty. Each has a small surgical ward of three beds. Behind these are the closed blocks (D), two female and one male, for more acute cases. They are also self-contained, with day and night wards, kitchen, baths, and lavatories. A home-like appearance has been studied and there are no long corridors, the wings of each block being separate wards opening out of the main building by glass doors. The decorations and furniture are simple and of modern design in pleasing colour; in the sitting rooms railway posters give an extra note of cheerfulness. In these blocks also there are some private and single rooms and several padded rooms for violent cases. Noteworthy are the two small convalescent villas (E) planned and furnished as nearly as possible to home conditions, looking out on lawns and orchards.

The grounds are still in process of development. Borders and shrubberies have been laid out and a large wooded area is to be cleared of brushwood for walking exercise within the boundary. The woodland has been left untouched where possible and there are many fine forest trees standing. The absence of fences, which is very gratifying to the practised eye, will, it is to be hoped, justify an optimistic experiment. Small hedges have



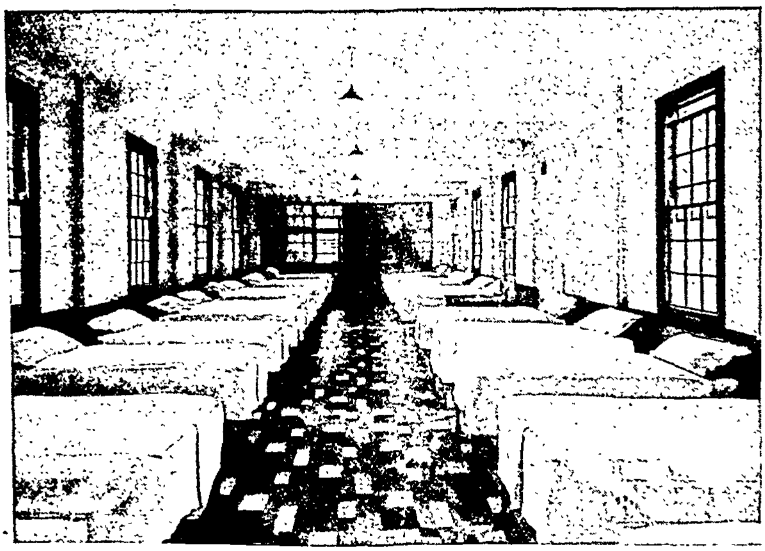
Lay-out plan of the hospital showing actual buildings in black, prospective buildings in outline



Admission hospital, south elevation

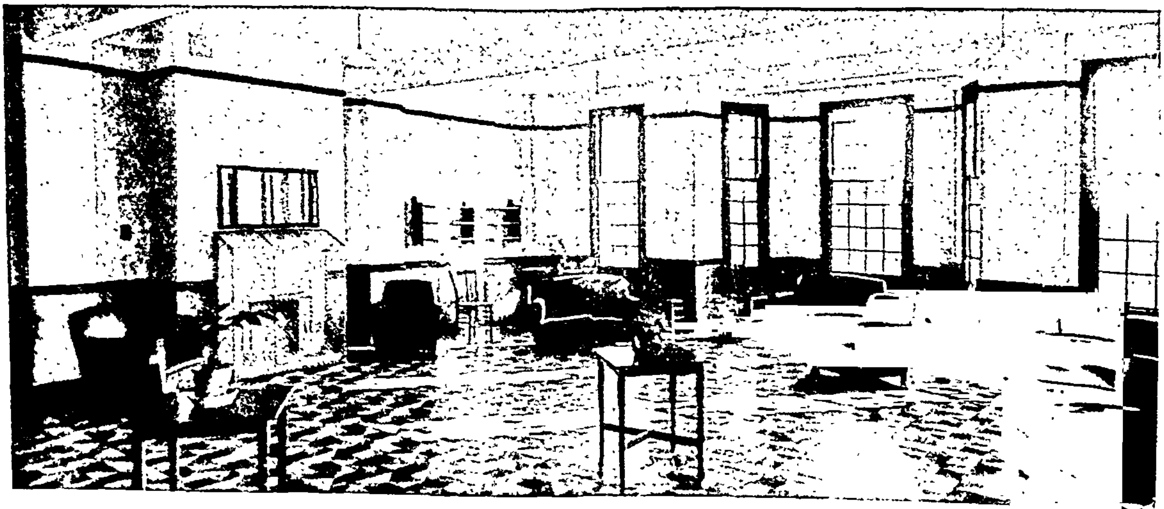
[Photos. by Hobbs, Ogden & Co.

been planted to divide the various blocks; otherwise they are only separated by paths. The fences round the closed blocks for acute cases are painted green, and it is hoped to have climbing plants on them. The usual institution brick walls are nowhere to be seen and there is nothing to suggest imprisonment to patients or their friends, or to offend the eye of neighbours.



One of the women's wards

The recreation room (F) in which the opening ceremony took place is a spacious hall, seating 1000 persons, with a floor of polished wood well sprung for dancing. The stage has modern lighting and curtains with dressing rooms for the performers; and underneath it chairs can be stored. The room is also equipped with a talking cinema and wireless, the latter being relayed to every ward in the colony. A



A day room for women

smaller room adjoining can be used for lectures or services. In it too refreshments can be secured during entertainments from a recess in direct contact with the kitchen. This is capable of cooking for 2500 persons by electricity or steam. The food is carried on insulated trolleys to the various blocks and the patients have all their meals in their own dining rooms. The menus are on a monthly system which allows for greater variety and avoids the foreknowledge of what dish is to be expected on a particular day of the week.

Variety has also been considered in the patients' dress; evidence for this is in the large store room behind the kitchen. There is no fixed uniform: the women have a choice of coats, skirts, and jumpers; the men a selection of tweed suits, shirts, and ties; so that a patient is not conspicuous outside the institution. Interest in clothes is regarded as conducive to self-respect. Occupational therapy is carried on in a separate building (G) with three large bright rooms, in addition to the large amount of similar work in the wards. The wool rugs, the cane wastepaper baskets, the trays and stools are testimony to what even chronic patients can be taught to do.

Of the other new buildings on the estate there are separate houses for the medical superintendent, Dr. G. W. Shore (H), and his deputy (J) as well as 24 cottages for the married male staff. The nurses' home (K) is a particularly bright and attractive house on the south side of the colony, self-contained with a separate kitchen of its own. Each nurse has her own room with hot and cold water laid on, the matron and assistant matron having their own small suites. A wide terrace overlooks a run of four tennis courts. The mansion (M) is not at present occupied, but it is hoped to use it later for private paying patients and early cases. A staff village occupies the north-east corner of the site.

This modern hospital for the rate-aided mental patient is a tremendous advance on the mental hospitals of even a few years ago, and will lead to emulation on the part of other county authorities that can contemplate the expense, which has so far been in the neighbourhood of £520,000. It would be desirable to give the general public very free access to this hospital and the opportunity to realise that the patients could not be better looked after in many private homes than they are here.

CORRESPONDENCE

TREATMENT OF MYASTHENIA GRAVIS WITH PHYSOSTIGMINE

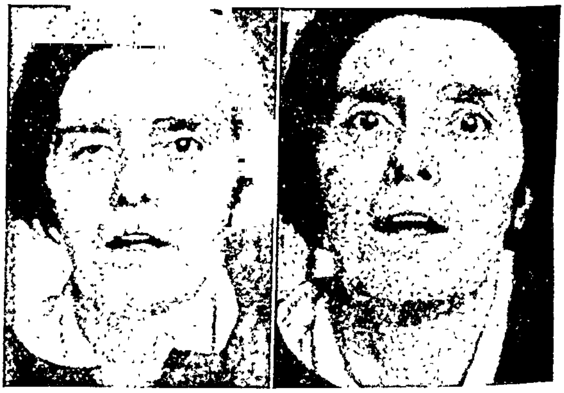
To the Editor of THE LANCET

SIR,—The abnormal fatiguability in myasthenia gravis has been thought to be due to curare-like poisoning of the motor nerve-endings or of the "myoneural junctions" in the affected muscles. It occurred to me recently that it would be worth while to try the effect of physostigmine, a partial antagonist to curare, on a case of myasthenia gravis at present in St. Alfege's Hospital, in the hope that it would counteract the effect of the unknown substance which might be exerting a curare-like effect on the myoneural junctions. I found that hypodermic injections of physostigmine salicylate did have a striking though temporary effect.

Mrs. M., aged 56, had had a previous attack of myasthenia gravis, lasting about six months, 14 years ago. Gastric ulcer four years ago. Non-specific infective arthritis seven months ago, now improved.

Towards the end of last February she found that she was unable to hold her shopping bag, and that her head used to fall forwards when she knelt to do the hearth. She had to remain in bed after March 18th, and had difficulty in sitting up. Her jaw then began to droop, she had to hold it up with her hand, and the left eyelid began to droop. Speech became indistinct when she was excited, swallowing was difficult, and fluid sometimes regurgitated through her nose. She was admitted to the hospital on March 28th, and a few days later weakness came on in the middle and ring fingers of both hands. The weakness is much increased by excitement, and is lessened by rest. It becomes worse as the day goes on. There is no wasting, and the tendon reflexes are all present. The masseters respond slightly or not at all to faradism; a myasthenic reaction has been obtained in the left deltoid. Radiograms show obsolete pulmonary tuberculosis. The thymus is not enlarged.

On April 11th treatment with hypodermic injections of physostigmine salicylate, gr. 1/60 once a day, was begun. In from half an hour to an hour after the injection the left eyelid "goes up" (see Figure), arm movements are much stronger, the jaw drops rather less, swallowing is improved, and the patient feels "less heavy." The effect wears off gradually in from 2–4 hours. With injections of gr. 1/50 the improvement is greater, and it lasts for 4–5 hours. Still greater improvement, lasting for 6–7 hours, followed an injection of gr. 1/45, but the patient felt rather faint and trembly, her "inside seemed all on the work," and she felt as if "something were going to happen." These feelings did not completely disappear till an hour after the injection. In all, 26 injections of physostigmine salicylate have been given. The effect is not quite uniform: on two occasions injections of gr. 1/45 and gr. 1/60 failed to produce any obvious effect. She feels better and more cheerful since the injections were begun.



Before injection the patient cannot raise her left eyelid. Thirty minutes after it the eye is fully open. (The photographs are reproduced from a cinematograph film and are reversed left for right.)

Given by the mouth, physostigmine salicylate gr. 1/60 produced no obvious effect, but an hour after gr. 1/30 slight improvement occurred. No improvement followed control injections of water, pilocarpine gr. 1/20, strychnine gr. 1/30, adrenaline ♏5, ephedrine gr. ½, or acetylcholine 0·05 and 0·1 g.

I think that this effect of physostigmine on myasthenia gravis is important, though it is only temporary, for it improves swallowing and might tide a patient over a respiratory crisis. It supports the opinion that the fatiguability is due to a poisoning of the motor end-organs, or "myoneural junctions," rather than to an affection of the muscle itself. It may be significant that physostigmine inhibits the action of the esterase which destroys acetylcholine. I have not had the opportunity of treating another case to confirm the findings. The administration of other drugs whose action resembles that of physostigmine is under consideration. It is also possible that physostigmine might be of some service in botulism and in cobra poisoning, in both of which a curare-like poisoning of the "myoneural junctions" of the respiratory muscles has been stated to be the main cause of death.

I wish to thank Dr. Philip Hamill for his interest and advice, and Dr. W. D. Wiggins, medical superintendent of the hospital, for permission to publish the case. I am, Sir, yours faithfully,

M. B. WALKER.

St. Alfege's Hospital, Greenwich, May 12th.

COLLAPSE THERAPY IN PNEUMONIA

To the Editor of THE LANCET

SIR,—The annotation on p. 1127 of your last issue leads me to seek the hospitality of your columns in order to state my views on the position of this method of treating pneumonia. Artificial pneumothorax is not to be regarded as a specific for lobar pneumonia; the induction may have no effect on the progress of the disease or may even make it worse. Used, however, strictly according to the technique described, I am convinced that a crisis can be produced in a few hours and the patient cured in the majority of cases. For this the correct technique is essential and disappointment has, I believe, been caused by failure to adjust the size or spacing of the fills. A four-hourly chart of the respiration-rate will help as a check on the progress of treatment.

The first fill must always be large, 350–550 c.cm., depending on the physique of the patient and the day of disease. The earlier the day, the larger the fill necessary, no attention being paid to the manometric readings. It will be found that in a few hours there will be a marked fall in the respiration curve, and if the fill is adequate the rate should drop to 22–25. The second fill, given 12–24 hours later, will require to be almost as large as the first, although as conditions should by now be more normal the pressure readings of the manometer can here be of some assistance. If the respiration-rate 12 hours after the first fill is under 25 the second fill can be postponed to 24 hours, but not longer. After the second fill the respiration-rate will steady at 20–22, and if this is maintained no further treatment is necessary. A temporary peaking of the curve to 25 can be disregarded, but if the curve again rises above 25 a third fill is advisable, while should it rise above 28 this fill is necessary. It need usually only be a small one, 200–250 c.cm., but it is wise to err on the side of overfilling as the air is absorbed very rapidly.

The technique thus elaborated is based on a definite conception of the pathology of lobar pneumonia and of the mechanism of the natural crisis.

I am, Sir, yours faithfully,

Hull, May 27th. J. J. COGHLAN.

BILATERAL EMPYEMA

To the Editor of THE LANCET

SIR,—The communication of Mr. D'Arcy McCrea in your issue of May 26th (p. 1117) attracted my attention, because I have had myself several cases of bilateral empyema: first as a chief physician of Imperial Sanatoriums in Russia and then during the war, especially in large hospitals in Finland. The first case I had was in 1909, at Irkutsk Hospital in East Siberia, which was demonstrated then by my senior colleague, Dr. N. Bessonoff. The method he applied, and which I followed with outstanding success afterwards and demonstrated to the students and my colleagues, is very simple. First of all it is necessary to replace the aspirated pus by saline solution with addition of a very dilute solution of iodine. This diminishes possibility of collection of pus in the cavity, leaving the pressure practically the same, also diluting and disinfecting the remaining contents. I used as a rule Potain's aspirator with two bottles connected with the same needle; one bottle with negative pressure, the other with positive. By changing taps I could either aspirate or introduce certain liquids. Bottles are graduated, so it was easy to reinstate the original pressure in the cavity. As a rule I introduced just a little less than I aspirated, in order to reduce the pressure somewhat. I never treated both sides simultaneously and always under control of X ray pictures before and after the manipulation. Unfortunately I had no chance to keep exact statistics, but the number of cases was not less than 80 and the mortality was very low.

I am, Sir, yours faithfully,

London, May 28th. B. PEROTT.

PETER DE ALCOBASSE

To the Editor of THE LANCET

SIR,—The quotation from Hutchins, "Hist. of Dorset," cited in the article on Alcobasse, Henry IV.'s physician, appearing in your issue of April 21st, obviously contains a blunder. One wonders what reason Hutchins can have had for making him into an Italian, with a hung, drawn, and quartered name. "Alcobasse" is clearly the Gallicised form of Alcobaça, about 80 miles north of Lisbon. The Cistercian Abbey was founded by Affonso Henriques, the first king of Portugal, and in Henry IV.'s time it was one of the largest and most powerful monasteries in Europe. Nothing would be more natural than that a physician should be selected from the successors to the Arabian culture in the Iberian Peninsula, and, as it is stated that Peter was born in Portugal, there seems no reason to doubt that he was educated, if not born, at Alcobaça. There might even be a connexion between his name and that of King Peter, whose tomb is in the Abbey, and who died in 1367—45 years before Henry IV.'s physician was admitted Dean of Westminster. Certainly this was a period of the closest associations between England and Portugal, cemented by the Treaty of Windsor in 1386, and by the marriage of John of Gaunt's daughter, Phillipa of Lancaster, in the following year to King John of Portugal, who was made a Knight of the Garter by Henry IV. in 1400.

I am, Sir, yours faithfully,

ALAN G. BODMAN.

Lisbon Medical Mission, May 25th.

ORGANISED TREATMENT OF MOTOR ACCIDENTS

To the Editor of THE LANCET

SIR,—In your report (p. 1137) of my paper on this subject at the Royal Institute of Public Health congress there is one slip that might lead to misapprehension. I am quoted as comparing the modern orthopædic hospitals to the military special hospitals "where the services of surgeons skilled in dealing with head and chest injuries would be available."

What I was actually trying to convey was that the network of orthopædic schemes with their central hospitals, which now covers Britain, was suitable for the work corresponding to that of the special femur and orthopædic hospitals provided by the War Office in the period 1914–18, if only the cases could be evacuated to them in a similar manner. Regarding head and chest cases, I remarked that at present the distribution of surgeons specially skilled in their treatment seemed dictated by chance, and I suggested that in future appointments to the surgical staff of local general hospitals areas should combine to secure the services of such men in reasonable numbers.

I am, Sir, yours faithfully,

M. F. FORRESTER-BROWN, M.S., M.D.

Bath, Somerset, May 27th.

LEFT-HANDEDNESS

To the Editor of THE LANCET

SIR,—The paper on left-handedness by Dr. C. J. Macalister in your last issue (p. 1151) will be welcomed by all who, from medical or educational experience have learned the importance of some of the associations of sinistrality. The suggestion offered by Dr. Macalister that stammering of the type to which he referred was due to imperfect transposition of function in the centres of the two sides of the brain was definitely supported in an investigation on left-handedness in relation to speech defects which I carried out with children of school age. Nearly 5000 boys were examined by means of a series of uni-manual and bi-manual tests, tests for the dominant eye, &c. The different types of dextrality and sinistrality were recorded on Rife's scheme (Psychological Review, 1922, xxix., 474). It was found that the tendency to speech disturbance was definitely related to departure from uni-laterality of function in the native organisation of the nervous system. Taking the whole of the subjects I found that in pure types for handedness (that is, RRR and LLL in Rife's scheme), 2·01 per cent. suffered from speech defects, whereas in the mixed types (LLR, LRR, RRL, and RLL), 11·8 per cent. suffered from speech defects.

"Crossing," which is probably the result of "partial or repressed transposition of the cerebral function," I found definitely increased the tendency to speech defect. All cases of pure dextrals with speech defects were submitted to eye tests and 41·4 per cent. were found to be left-eyed. In addition to the tendency, which others have suggested and this investigation supports, for sinistrality to be associated with a higher proportion of speech disturbances, my results proved that crossing, whether sinistrals with dextro-ocularity or dextrals with sinistro-ocularity, apparently increases the tendency to speech disturbance. If mixed types and crossing are related to imperfect transposition of function to which Dr. Macalister refers, then our data supports his contention. It was also found that nervous disability was two and a half times as frequent in the crossed groups as in the non-crossed groups. This tended to support Quinlan's hypothesis (Arch. Neur. and Psychiat., 1922, vii., 352) that such crossed functioning is evidence of a psychopathic constitution.

Reference is made to cases of "left-handed children who only began to stammer when an attempt was made to convert them into right-hand writers." It would appear from evidence that has been accumulated by various workers on the question that forced change of hand, may, or may not, cause speech defect. I suggest that this is fundamentally related to asymmetry of native organisation, and may be explained on the lines of the hypothesis I offered (Forum of Education, June 2nd, 1929) that speech defect is causally related to mixed types of sinistrality. The suggestion that partial or repressed transposition of the cerebral function "had given no trouble until the upsetting of the balance had been brought about by fright or emotional causes" is in close accord with the theory suggested by Dr. W. S. Inman (THE LANCET, 1924, ii., 211) that left-handedness and stammer have a common origin in some form of mental stress. The left-handed person is "often distinguished by being, to a greater degree than his fellows, self-reliant, critical, and obstinate, refusing to be driven but accepting guidance from those he loves." The forcible restraint upon left-handedness may, therefore, involve psychological difficulties of the greatest importance.

I am, Sir, yours faithfully,

DAVID W. OATES.

Newport (Mon.) Secondary School for Boys, May 29th.

HOSPITAL MANAGEMENT

To the Editor of THE LANCET

SIR,—In THE LANCET of March 31st (p. 704) Mr. Duncan Fitzwilliams is reported to have stated :—

> "that medical schools played an important part in the hospital system but did not make up the whole of it. The pride of the profession in the voluntary system had gone hand-in-hand with a neglect to study hospital management. Hospitals were governed by the finance sub-committee, which in turn was governed by the amount of its bank balance, and every finding of this subcommittee was passed by the complaisant board. The King's Fund had done most to improve matters; the statutory committee had produced an excellent survey, the British Hospitals Association had done nothing at all. . . ."

I have written twice to Mr. Fitzwilliams asking him to let me know upon what grounds he has stated publicly that "the British Hospitals Association had done nothing at all." I have not had the courtesy of a reply.—I am, Sir, yours faithfully,

R. H. P. ORDE,

Hon. Sec. British Hospitals Association.

Grosvenor-crescent, S.W., May 24th.

CHILDREN'S HOSPITALS.—The report for 1933 of the Hospital for Sick Children, Great Ormond-street, shows that 6723 in-patients were admitted, the average number of beds occupied daily was 226, the average weekly cost of each in-patient was £4 1*s.* 1*d.*, and the average total cost of each in-patient was £7 1*s.* 10*d.* There were 28,484 new out-patients whose average cost was 8*s.* 9*d.* A fall in the number of both classes of patients may, it is suggested, be attributed to the higher general standard of health. During the year only £11,655 was collected towards the cost of reconstruction, whereas the board had set out to raise £500,000. The rebuilding of the nurses' home is nearly complete, and an extension of the out-patient department, including a new electrotherapeutic department, has been made.

At the annual meeting of the Victoria Hospital for Children, Chelsea, it was pointed out that while the maintenance of the institution and the convalescent home at Broadstairs costs £25,000 a year, the income from investments is less than £3500. The hospital is anxious to enlarge its accommodation, but it "has never embarked on building operations without the money to pay for them."

Last year the Belgrave Hospital for Children, Clapham, received 1717 in-patients and treated 11,366 out-patients, a reduction in the latter category, attributed to the improved health of the locality and the fine weather. Thanks to legacies, income exceeded expenditure by £1280. The report states that the hospital is not large enough for the needs of the neighbourhood, that the out-patients' department is "lamentably overcrowded," and a nurses' home "an urgent necessity." The average weekly cost of each in-patient was £3 4*s.*

OBITUARY

ANDREW FULLERTON, M.D., M.Ch. Belf., F.R.C.S.I., C.B., C.M.G.

EMERITUS PROFESSOR OF SURGERY, QUEEN'S COLLEGE, BELFAST

WE regret to record the death of Prof. Fullerton, the well-known Belfast surgeon, which occurred on May 22nd in the sixty-sixth year of his age.

PROF. FULLERTON

[*Photograph by Lafayette*

Andrew Fullerton was the third son of the late Rev. Alexander Fullerton, of Dalkey, was born in County Cavan, and was educated at Lurgan College, Belfast, proceeding for his medical training to Queen's College. He faced great difficulties in his early life, being an assistant to a Belfast practitioner while he was a student, and working late at night or early in the morning to keep level with his studies. His industry met with success, for, securing prizes and scholarships, he graduated as M.B., B.S. R.U.I. in 1890 with first-class honours. He now maintained himself by teaching anatomy and surgery and engaging in what general practice fell to him. He came to England and acted for a period as house surgeon at the Miller Hospital, Greenwich, and at the West Kent Hospital, Maidstone, but in 1898 he returned to Ireland, being appointed assistant surgeon to the Belfast Hospital for Sick Children. In 1902 he obtained the diploma of F.R.C.S.I., acted as demonstrator of anatomy at Queen's College, and was elected to the staff of the Royal Victoria Hospital, where he already held the Coulter exhibition. This was to be the main field of his surgical activities in the ensuing 41 years.

Gradually his interests, though remaining broad, became focused on genito-urinary surgery, in which he rapidly became proficient, and on this sphere of his work we may quote the following communication received from Prof. R. J. Johnstone, who writes:

"When Andrew Fullerton became an assistant surgeon to the Royal Victoria Hospital urology was still. from the standpoint of to-day, in an embryonic stage. The *electric cystoscope* had been invented and was being used by a few enthusiasts, but it was regarded by most surgeons as merely another surgical toy. Fullerton saw the possibilities of the instrument, he set himself to learn how to use it and long hours of arduous practice made him its master. As one improvement followed another and the range and the scope of cystoscopy widened. he kept himself abreast. and, by the aid of the instrument of *precision* finally evolved. he was able to make those observations and to draw those deductions which have long ago given him an assured place among the leaders of modern urology. His attitude towards his own specialty was typical of the man. Whatever the subject with which he had *to do,* he was quite content to start as a novice and a learner, but he was never satisfied with anything less than mastery—the best of which he was capable, whether it was the performance of an operation, the delivery of a lecture or of a speech, or the achievement of a drive at golf. He had the passion for perfection, and that quality which has been held to be the mark of genius, an infinite capacity for taking pains."

In 1915 Fullerton went to France with the position of consulting surgeon to the B.E.F.; he was appointed to the Boulogne area in succession to the late Mr. F. F. Burghard, and there his special knowledge of urology and general surgical experience was an asset to the younger surgeons and surgical specialists in the area. In three and a half years' service he was awarded the C.B., C.M.G., and was mentioned thrice in dispatches. In France he came in contact with the McGill and Harvard University units, and after the war was invited to Canada and the United States, where he received the Honorary Fellowship of the American College of Surgeons.

In 1923 Andrew Fullerton succeeded Prof. Thomas Sinclair in the chair of surgery at Belfast, an office which he relinquished only last year. In 1926 he was elected President of the Royal College of Surgeons in Ireland and was reappointed the following year. A distinction which he prized most highly fell to him in 1931, when he was made President of the Association of Surgeons of Great Britain and Ireland. As a surgeon he was best known for his genito-urinary work. He was one of those who stressed the value of unilateral diuresis in obscure cases where other methods of examination proved negative. He modified the technique of prostatectomy from time to time and was a firm adherent to the Freyer type of operation with suprapubic enucleation at one stage, and had reduced his mortality to about 5 per cent. In his ward he took great pains with the case-notes and himself kept a record of both hospital and private cases. This extended back to his days as resident in hospital, and at the time of his death he had full records of some 3600 cystoscopies alone. No day was complete until he had written up his case-notes. As a writer he published over 50 papers of surgical interest, the articles on gunshot wounds of the kidney and ureter finding a place in the official medical records of the war.

With such a record it is not to be wondered that the man Andrew Fullerton had an arresting personality, and he possessed also a most likeable disposition. As in the war, so in civil life he was always kindly, considerate, and helpful to the student or young doctor who regarded him as a personal friend and loved him for his enthusiasm and guilelessness. His enthusiasm was infectious, and no one could work for him without sensing it and feeling the better for it. On his retirement his students gave him a remarkable testimony of their goodwill and devotion to a popular teacher. With all his activities Andrew Fullerton found time to enjoy his private life. He was a warm host and had a large circle of friends and was a prominent freemason. Golf was his chief recreation, and for the past two years he was captain of the Royal County Down Club at Newcastle.

Dr. J. C. Rankin writes appositely here:—

"Prof. Fullerton's operative and consulting work, together with his very careful and elaborate case-taking, left him with little time for other pursuits. His mind was always centred on his work, so that at times he may have seemed abrupt in his manner, but in lighter moods he could relax very completely.

At golf, his favourite recreation, he played keenly, never admitting defeat till the last put, and while a modest winner he was a most cheerful loser. At bridge, though his calls were at times optimistic, he brightened up the game and always made the best of his hand. He was an asset to any party, and, as generous host, he entertained many distinguished visitors to our school. In all he did he put his whole heart."

Prof. Fullerton was married twice, and is survived by his widow and the two sons and daughter of the first marriage.

OTTO JACKSON KAUFFMANN, M.D., F.R.C.P.

EMERITUS PROFESSOR OF MEDICINE, UNIVERSITY OF BIRMINGHAM

THE sudden death occurred on May 15th, at his house at Edgbaston, Birmingham, of Otto Kauffmann, emeritus professor of medicine and consulting physician to Queen's Hospital, Birmingham.

Otto Kauffmann when only 15 lost his father and was brought up by his mother, to whom he was devoted, and who lived with him until her death at the age of 89. He received his early education at Owens College, Manchester, and completed his medical curriculum at St. Mary's Hospital, London. Taking the M.R.C.S. in 1885, in the following year he graduated M.B. Lond. and M.B. Manch. Two years later he proceeded to the M.D. degree, London, when he qualified for the gold medal. He proceeded to hold many residential appointments; he was house physician at the Brompton Consumption Hospital, at the Seamen's Hospital, Greenwich, and at the Manchester Royal Infirmary, where he later became resident medical officer. In 1893 he was elected to the staff of Queen's Hospital, Birmingham, and his appointment to the chair of pathology attached to Mason University College followed.

PROF. KAUFFMANN

[*Photograph by A. C. Cooper*

For a long period he was a prominent figure in the medical school of the university, and in 1913 was elected professor of medicine, a post that he occupied with distinction for 13 years, during the closing period being chairman of the clinical board. This period corresponded with the years of the war, and while discharging his hospital and academic duties he did excellent work, with the rank of Lieut.-Colonel, R.A.M.C., at the first Southern General Hospital.

Kauffmann displayed in the Ingleby lectures, which were delivered in 1900 and published in these columns, his particular interest in many phases of neurology. He dealt with the common neuroses of childhood, and although much addition to our knowledge has been gained in the interval, his appreciation of the real nature of many of the conditions formed useful steps in the increasing comprehension of the causation of many of these neuroses. His observations were carried out in a thorough manner, and his main arguments remain sound. He was not a controversalist and relied for his teaching on his experiences in clinical medicine. In 1921 the Association of Physicians of Great Britain met at Birmingham, when election as president proved the opinion of his work formed by the leaders of scientific medicine. He also served the British Medical Association in many capacities, having been, at different annual meetings, vice-president of the section of pathology, while at the meeting in 1911, at Birmingham, he presided over the section of diseases of children.

The following appreciation comes from a colleague of Kauffmann: "It is permitted to comparatively few to have so little illness as clouded the 71 years of Otto Jackson Kauffmann's life. His good health was no doubt the secret of his youthful appearance. It will be a surprise to his friends to learn that he was born in 1863. He died, without suffering, from cerebral thrombosis in the midst of all his activities. He was a most gifted and cultured man with a very philosophical and analytical mind. He was a great reader, but the modern novel was anathema to him. Books on travel, biography, astronomy, and navigation interested him most, he was a great lover of Shakespeare, and well versed in French and German literature, both lay and medical. It is a matter of great regret that one so eminently fitted to write on medical subjects should have made so few contributions to the literature, but, perhaps, in becoming critical of others he had become too self-critical to express definite views. Mathematics and music are said to appeal to the same mentality and this was certainly true of Kauffmann. He was never happier than when engaged in trying to solve some mathematical problem, or when left to the companionship of his violin. He was a very keen violinist and for years had been in the habit of forming one of a quartette that met every week at his house.

"Kauffmann had an amazing command of English and would put this to good use whenever he spoke in public. He was an interesting lecturer but it was in the wards of the Queen's Hospital, Birmingham, that he was in his element. He always attracted a large number of students. To these he gave of his best and, as he was both thorough and methodical, his teaching was of the utmost value. He loved teaching and delighted in unravelling the medical problems that presented themselves in the wards. He visited the hospital on most days; Saturdays, however, never saw him there, for in the winter he hunted every Saturday and, for many years, he was a well-known figure at meets in the Midlands. He made up for his absence in the wards on the sixth day by his presence there on the seventh, and every Sunday morning would find Kauffmann in the wards surrounded by a number of practitioners discussing knotty medical problems. This Sunday meeting, to which he used to refer as his Sunday-school, may be said to have been the origin of post-graduate teaching so far as Birmingham is concerned. It was very popular with the doctors attending, but not so popular with the resident and nursing staffs, as may be readily imagined. His recreations were hunting in winter and yachting in summer. He sailed his yacht without paid hands and knew every mile of the coast of Cornwall, Devon, and the Scilly Isles, and many parts of Scotland and Ireland."

Professor Kauffmann married Rosalind, the granddaughter of Mr. Justice Crumpton, and leaves a widow, a daughter, and two sons, the elder of whom is training for the medical profession.

MEDICAL NEWS

University of Cambridge

On May 26th the following degrees were conferred :—

M.D.—W. S. Maclay, M. D. Nosworthy, R. W. Windle, and J. B. S. Lewis.

M.B. B.Chir.—G. W. Whittall and E. R. Hargreaves.

M.B.—J. G. Jones.

B.Chir.—C. M. Barker.

Dr. G N. Myers has been appointed university demonstrator in pharmacology, and Dr. H. A. Krebs in biochemistry.

The E. G. Fearnsides scholarship for clinical research on the organic diseases of the nervous system is open to men or women who are graduates of the university in medicine or who have passed part II. of the natural sciences tripos after graduation in arts. Applications should be sent to the university registrary before June 27th.

Society of Apothecaries of London

At recent examinations the following candidates were successful :—

Surgery.—P. E. Cresswell, Univ. of Oxf. and Guy's Hosp. ; M. T. Curran, Univ. of Leeds ; R. Fleming, London Hosp. ; S. Kay, Univ. of Toronto ; S. Klein, Univ. of Vienna and St. Mary's Hosp. ; R. Sugerman, Univ. of Basle and Royal Free Hosp. ; C. E. Wetherall, Royal Free Hosp. ; and W. E. Whaite, Univ. of Manch.

Medicine.—P. C. Alexander, Univ. of Oxf. and Guy's Hosp. C. N. Chowdary, Univ. of Durham ; G. W. Hardy, St. Mary's Hosp. ; C. C. Joannides, Univ. of Graz and Westminster Hosp. ; S. Kay, Univ. of Toronto ; A. G. Manley, St. Mary's Hosp. ; J. Mason, Middlesex Hosp. ; S. E. Roberts, Guy's Hosp. ; and E. C. Rowlands, St. George's Hosp.

Forensic Medicine.—P. C. Alexander, Univ. of Oxf. and Guy's Hosp. ; F. M. Chalkley, Charing Cross Hosp. ; M. V. Matthew, Univ. of Manch. ; and M. A. Walsh Conway, Charing Cross Hosp.

Midwifery.—A. E. Ginn, Guy's Hosp. ; L. A. Lewis, King's Coll. Hosp. ; and H. Paroulakis, Univ. of Innsbruck and St. Mary's Hosp.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery : P. C. Alexander, A. E. Ginn, G. W. Hardy, S. E. Roberts, E. C. Rowlands, R. Sugerman, and C. E. Wetherall.

University of London

Applications are invited for the Laura de Saliceto studentship for the advancement of cancer research. Particulars will be found in our advertisement columns.

University of Liverpool

Dr. Henry Cohen, lecturer in medicine in the university and physician to out-patients at the Liverpool Royal Infirmary, has been appointed to the chair of medicine as from Oct. 1st. in succession to Prof. John Hay, who retires at the end of the present session.

Dr. Cohen, who was born in 1900, was educated at Birkenhead Institution and Liverpool University, where he had a distinguished career as a student. [illegible] in 1922 with first-class honours and two [illegible] to the M.D. degree, with special merit. A[illegible]ointments at the Royal Infirmary he be[illegible]nd registrar there. He has held the Samu[illegible] and in 1924 a Beit memorial research fell[illegible] he was admitted to membership of the Royal College of Physicians of London, and this year he was elected a fellow.

International Anthropological Congress

The first session of the International Congress of Anthropological and Ethnological sciences will be held in London from July 30th to Aug. 4th. Meetings will take place at University College, Gower-street, W.C., and at the Wellcome Historical Medical Museum, Euston-road. The chairman of the section of anatomy and physical anthropology will be Prof. G. Elliot Smith, F.R.S, and the chairman of the section of sociology Prof. C. G. Seligman, F.R.S. The other sections will be devoted to psychology, demography and population problems, technology, religions, and language and writing. The president of the congress is Lord Onslow, and the secretaries should be addressed c/o The Royal Anthropological Institute, 52, Upper Bedford-place, W.C.1.

Vacation Course in Paris

A vacation course in medical therapeutics and hydrology will be held from June 18th to 30th at the Hôpital Necker, and a tour to Royat and Saint-Nectaire has been arranged for June 30th to July 1st. Further particulars may be had from the secretary of the faculty of medicine of the university. Prof. Maurice Villaret is acting as director.

Indian Medical Service Annual Dinner

This dinner, as already announced, will be held at the Trocadero Restaurant, London. on Wednesday, June 20th, at 7.15 for 7.30 P.M. Major Sir Leonard Rogers will preside, and officers can arrange to sit near their friends as separate tables to seat eight will be provided. Tickets from the joint hon. secretary, Sir Thomas Carey Evans, Hammersmith Hospital, Ducane-road, W.12.

Coming Sales of London Hospital Sites

Presiding at the annual court of governors of St. George's Hospital last week, Prince George stated that the site must be sold and a new building erected within the next four or five years. "Everything about the hospital except the wards," he added, "is out of date and quite unfit for modern requirements." Sir Crisp English, consulting surgeon to the hospital, urged immediate action on the ground that the institution is rapidly reaching a crisis. He described the site as "the best in London."—The site and buildings and the various annexes of Westminster Hospital are now bring advertised for sale.

National Birth Control Association

A conference on birth control for general nurses, public health workers, and midwives will be held at the College of Nursing, Henrietta-street, London, W., on Friday, June 15th. In the morning, under the chairmanship of Lord Horder, Mr. Claude Mullins will speak on the ethics of birth control, and Mrs. Stocks on birth control and the public health service. In the afternoon Lady Denman will take the chair, and Dr. Helena Wright will give a lecture on the technique of birth control, and Mr. Cedric Lane-Roberts on the contribution of the nursing profession. Tickets can be obtained from the secretary of the Association, 26, Eccleston-street, London, S.W.1.

Royal National Pension Fund for Nurses

At the annual meeting last week Sir Eric Hambro, the chairman, said that for the third year in succession the fund had made a record. Whereas in 1931 the policies issued numbered 1501, last year they reached 2438. The premium income in 1933 was £262,000, an increase largely due to many nurses having paid single premiums for the purchase of immediate or deferred annuities. Last year the single premiums amounted to £147,000. Sir Eric added that during the year the fund increased by £206,000, and on Dec. 31st last amounted to £2,700,000, of which £1,460,000—or more than 54 per cent.—was invested in British Government securities. The fund was now paying annuities at the rate of £144,000, and the number of annuitants was more than 4000. After deducting tax and allowing for refunds the net rate of interest earned for the year on the annuity and life fund was £4 18*s*. 3*d*. per cent.

Liverpool Hospital for Consumption and Diseases of the Chest

The report for 1933 of Dr. E. T. Baker-Bates, the stipendiary medical officer, shows that there were 131 patients under treatment (81 females and 50 males), whose average residence was 91 days. There were 98 "discharges," which included 25 deaths. On admission there were 78 per cent. of advanced, 18 per cent. of moderate, and only 4 per cent. of early cases. Advanced cases after admission "show a certain degree of improvement, hold their own for a time, and then gradually lose ground ; such patients eventually become bedridden and helpless." The radiological examination of contact cases of pulmonary tuberculosis has been found to be of the greatest value.

PARLIAMENT

NOTES ON CURRENT TOPICS

Reassembly after Whitsun

THE House of Commons reassembled after the Whitsuntide recess on Tuesday, April 29th.

Milk for School-children

The Children's Minimum Organising Committee has circulated to Members of Parliament a memorandum criticising the Government's proposals for assisting the milk industry. The committee, which has the support of 32 organisations, emphasises the value of increasing consumption of liquid milk in schools as opposed to the encouragement of further production of milk for manufacture. The present proposals provide for the supply of milk to schools at ½d. for a third of a pint, and "it is estimated that under this scheme cheap milk could be supplied on schooldays to only 2–2½ million out of the 6½ million children attending elementary schools." Moreover, none would be available for children under 5 or for expectant and nursing mothers, or for school-children during the holidays. As an alternative the committee desires that "the Government should use whatever money is available as a direct grant to local education authorities to provide a daily ration of clean milk in elementary schools for all children who can take it." Local authorities should also be obliged to supply milk for children under 5 and for expectant and nursing mothers in households where the family income falls below a sum necessary to maintain full health. If this alternative is not adopted the committee urges that it shall at least be made compulsory on all local education authorities to supply free milk to necessitous children.

Restoration of Salary Cuts

On May 29th the House of Commons considered in Committee the Statutory Salaries (Restoration) Money Resolution.

Mr. CHAMBERLAIN (Chancellor of the Exchequer), in moving the resolution, said that abatements which were made in salaries and allowances in 1931 would be restored by one-half by administrative action where that was possible. Certain salaries, however, were fixed by Statute, which required legislation to restore abatements, and the resolution was moved to enable the legislation to be introduced. The first paragraph of the resolution went further than was necessary to restore half the abatements made in 1931, and would authorise a Bill to restore the other and second portion of the abatements at some future time, if it was thought desirable to do so, without the necessity for further legislation. There was no intention of restoring to the full all the cuts made in 1931 in this particular financial year. They would have to wait their turn until a full restoration could be made everywhere; then they would all come together.

The resolution was agreed to.

HOUSE OF COMMONS

TUESDAY, MAY 29TH

Duties on Scientific Publications

Captain CUNNINGHAM-REID asked the President of the Board of Trade if he would consider excluding from the operation of the Additional Import Duties (No. 6) Order, 1934, the publications of learned and scientific societies.—Mr. HORE-BELISHA (Financial Secretary to the Treasury) replied: The question of excluding the publications of learned and scientific societies from the operation of the Additional Import Duties (No. 6) Order, 1934, is one, in the first instance, for the consideration of the Import Duties Advisory Committee, to whom any representation should be made by the parties concerned.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY, June 6th.

Surgery. At the Mount Vernon Hospital, Northwood. 4.30 P.M. Demonstrations: Dr. Malcolm Donaldson, Mr. S. Cade, Mr. W. D. Harmer, Mr. G. L. Keynes, Mr. D. C. L. Fitzwilliams, Mr. B. W. Williams, Dr. G. C. Fairchild, and Dr. J. C. Mottram.

FRIDAY.

Ophthalmology. 5 P.M. (Cases at 4.30 P.M.) Annual General Meeting. Mr. A. C. Hudson and Sir William Lister: Hypernephroma of Iris. Miss M. A. Pugh: The Significance of False Projection in Squint. Cases will be shown.

Laryngology, Otology. Summer Meeting at Birmingham. 10 A.M.–12.30 P.M., at the Medical Institute: Discussion on the After-treatment of Facial Palsy to be opened by Sir Charles Ballance on Nerve Anastomosis, and Sir Harold Gillies on Treatment by Fascia Lata Slings. 2.30 P.M.–4.15 P.M. Mr. Steven Jones: Normal Phonation and Articulation. Mr. V. E. Negus: Disorders of Phonation. One demonstration: Miss Freda Parsons: Speech Re-education Methods.

SATURDAY.

9.30 A.M.–12.30 P.M., at the Board Room, General Hospital. Cases: Sir Harold Gillies, Mr. W. S. Thacker-Neville, Mr. C. Hamblen Thomas, Mr. Harold Round, and Prof. Lockhart.

RESEARCH DEFENCE SOCIETY.

TUESDAY, June 5th.—3 P.M. (at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C.), Prof. J. Barcroft: Experiments on Man (Stephen Paget Memorial Lecture).

SOUTH-WEST LONDON MEDICAL SOCIETY.

WEDNESDAY, June 6th.—9 P.M. (at the Bolingbroke Hospital, Wandsworth), Mr. Comyns Berkeley: Some Things I Have Learnt (Bolingbroke Lecture).

BIOCHEMICAL SOCIETY.

FRIDAY, June 8th.—2.30 P.M. (Institute of Physiology, Glasgow): Communications.

SATURDAY.—Visit to Hannah Dairy Research Institute, Ayr, in the morning: and to Marine Biological Station, Millport, in the afternoon.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, June 5th, and following THURSDAY.—5 P.M., Prof. O. L. V. S. de Wesselow: On Arterial Hypertension (first two Croonian Lectures).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, June 4th, to SUNDAY, June 10th.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. All-day Course in Gynæcology.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Afternoon Course in Venereal Disease.—CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C. Week-end Course in Obstetrics: all day, Sat. and S [illegible] LONDON, 11, Chandos-stree [illegible] re on Poor Circulation [illegible] r, at 2.30 P.M. on Tues. [illegible] ITAL, Hampstead-road, N.W. Lantern lecture-demonstration on surgical cases by Mr. Hamilton Bailey at 3 P.M. on Sat.—PANEL OF TEACHERS. Individual clinics in various branches of medicine and surgery are available daily. Courses of instruction arranged by the Fellowship of Medicine are open only to Members and Associates.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, June 5th.—3.30 to 5 P.M. (at the General Hospital), Prof. Seymour Barling: Demonstration of Surgical Cases.

FRIDAY.—3.30 to 5 P.M., Dr. Hugh Donovan: Urinary Infections and the Ketogenic Diet.

LEEDS GENERAL INFIRMARY.

TUESDAY, June 5th.—3.30 P.M., Dr. Vining: Children.

DONATIONS AND BEQUESTS.—From Smith's Charity the Royal National Orthopædic Hospital has received a donation of £1000, and King's College Hospital from the same charity a special grant of £500 towards the completion of the nurses' home, and a gift from a citizen of Lambeth of £1000 towards the reduction of the debt of over £60,000.—By the will of the late Dr. J. T. Rogerson, of the Isle of Man, the Victoria University of Manchester will receive ten £100 five per cent. first mortgage debentures of the Trafford Park Estates, Ltd., and benefit by part of the residue of the estate.—The late Mrs. Mary G. Letford, of Ramsgate, left £1000 to the Star and Garter Home for Disabled Soldiers and Sailors, Richmond, to endow "The Louis George Letford Bed," and £500 to the Ramsgate General Hospital and Seaman's Infirmary to endow "The Louisa Worthington Cot."

Appointments

Kirby, M., M.B., Ch.B. N.U.I., has been appointed Asst. County M.O.H., Dublin.

Mill, W. A., M.S. Lond., F.R.C.S. Eng., Laryngologist to the Cancer Hospital (Free).

Moncrieff, Alan A., M.D., F.R.C.P. Lond., Physician to Out-patients, at the Hospital for Sick Children, Great Ormond-street, London, W.C.

Risk, R. S., M.B., B.S. Lond., Resident Medical Officer at the Queen's Hospital for Children, Hackney-road, E.

Simpson-Smith, A., M.Chir. Camb., F.R.C.S. Eng., Surgeon to the Hospital for Sick Children, Great Ormond-street, London, W.C.

West London Hospital: Gordon, H., B.Chir. Camb., Dermatologist; and Hasler, J. K., M.B., B.S. Lond., Assistant Anæsthetist.

Certifying Surgeons under the Factory and Workshop Acts: Ashton, J. C., M.B., Ch.B. Edin. (Corris, Montgomeryshire); and How, G. R., M.B., Ch.B., St. And. (Kilbirnie, Ayrshire).

Vacancies

For further information refer to the advertisement columns

Bagdad, Royal College of Medicine.—Chair of Materia Medica.

Bath, Royal United Hospital.—Hon. Med. Reg.

Beckenham, Bethlem Royal Orchard, Monks Orchard.—Sen. Asst. Phys. £700.

Blackburn Royal Infirmary.—Res. Cas. O. £150.

Bristol Royal Infirmary.—Hon. Physician, Hon. Asst. Phy., Hon. Reg. to Orthopædic Dept. Also Hon. Anæsthetist.

Bristol, Winford Orthopædic Hospital.—Hon. Dental Surgeon.

Cambridge University.—E. G. Fearnside's Scholarship for Clinical Research, &c.

Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100. Also Second Asst. Pathologist. £250.

Cardiff Royal Infirmary.—H.S. for Ear, Nose, and Throat Dept. £100.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Assts. for Out-Patient Dept.

Charing Cross Hospital Institute of Pathology, W.C.—Part-time Bacteriologist and Hæmatologist. At rate of £250.

Chesterfield, Walton Sanatorium.—Locum Res. Asst. M.O. At rate of £350.

Connaught Hospital, Walthamstow, E.—H.S. At rate of £100.

Dewsbury and District Infirmary.—H.S. £150.

Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. At rate of £110.

Durham C.C.—District Tuber. M.O. £500.

Evelina Hospital for Sick Children, Southwark, S.E.—H.P. At rate of £120.

Gloucester, Gloucestershire Royal Infirmary, &c.—Res. H.P. and Res. H.S. Each at rate of £150.

Great Yarmouth General Hospital.—H.S. £140.

Guy's Hospital, London, S.E.—Asst. M.O. to Salomon's Infant Welfare Centre. At rate of £78. Also Ophthalmic Surgeon.

Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—H.S. At rate of £100.

Hampstead Metropolitan Borough.—Public Vaccinator.

Hospital for Sick Children, Great Ormond-street, W.C.—Physician to Skin Department.

Hospital for Tropical Diseases, Gordon-street, W.C.—H.P. At rate of £120.

Hull Royal Infirmary.—Third H.S. At rate of £150.

Ilford, King George Hospital.—Cas. O. At rate of £130.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. £120.

Lancashire C.C., School Medical and Child Welfare Dept.—M.O. £800.

Lancaster, Royal Albert Institution for the Feeble-minded.—Jun. Asst. M.O. £430.

L.C.C.—Radiologist. £1500.

London Hospital, E.—Physician.

London Missionary Society.—Medical Woman for Jiaganj, N. India.

London University.—Chair of Obstetrics and Gynæcology. £2000. [illegible] Also Laura de Saliceto Studentship. £150.

[illegible] *Hospital for Women and Children.*— [illegible]

Manchester Royal Children's Hospital.—Asst. Surgeon. £50.

Mansfield, Notts, Harlow Wood Orthopædic Hospital.—Two H.S.'s. Each at rate of £175.

Metropolitan Ear, Nose, and Throat Hospital, 2, Fitzroy-square, W.—Asst. Surgeon.

Middlesbrough, North Riding Infirmary.—H.P. At rate of £125.

Mildmay Mission Hospital, Austin-street, Bethnal Green.—Asst. Cas. O. At rate of £125. Also Jun. Res. M.O. At rate of £100.

Nelson Hospital, Merton, S.W.—Res. H.S. At rate of £100.

Norwich, Norfolk and Norwich Hospital.—H.P., H.S., and H.S. to Spec. Depts. Each £120.

Penshurst, Cassel Hospital for Functional Nervous Disorders, Swaylands.—Medical Director. £1000.

Plymouth, South Devon and East Cornwall Hospital.—H.P. and H.S. Each at rate of £120.

Preston County Borough.—Asst. School M.O. £500.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Two Res. Anæsthetists. Each £100.

Queen's Hospital for Children, Hackney, E.—H.P. and Cas. O. Each at rate of £100. Also Surgeon for Ear, Nose, and Throat Dept.

Royal Dental Hospital of London, Leicester-square, W.C.—Hon. Pathologist.

Royal London Ophthalmic Hospital, City-road, N.—Hon. Asst. Phys.

Royal Northern H[illegible] rate of £70.

Ryde, Royal Isle [illegible] H.S. £180.

St. Peter's Hosp[illegible], *W.C.*—Hon. Clin. Assts. to Out-Patient Dept.

Salford Royal Hospital.—Med. Reg. £250. Also H.P. and H.S. Each at rate of £125.

Salvation Army, Mothers' Hospital, Lower Clapton-road, E.—Jun. Res. M.O. At rate of £80.

Sheffield Children's Hospital.—H.S. At rate of £100.

Sheffield, Jessop Hospital for Women.—Two H.S.'s. Each at rate of £100.

Stockport Infirmary.—H.S. £150.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Hon. Radiologist. Also H.S. At rate of £150.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £100.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Jun. Res. H.S. At rate of £100.

West London H[illegible] H.P., H.S. and Res. Anæ[illegible]

Wigan Royal I[illegible]

Winchester Royal Hampshire County Hospital.—H.S. At rate of £125.

Wolverhampton Royal Hospital.—H.S. for Ear, Throat, and Nose Dept. At rate of £100.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £150.

Wolverhampton, New Cross Hospital.—Asst. Res. M.O. £200.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Oakengates, Salop, and at Filey, Yorks.

Births, Marriages, and Deaths

BIRTHS

Baynes.—On May 21st, at Reed House, Old-avenue, West Byfleet, the wife of Dr. H. Godwin Baynes, of a son.

Darley.—On May 23rd, at Trory Cottage, Claygate, Surrey, the wife of Rupert D. Darley, M.B., B.S. Lond, of a daughter.

Gibson.—On May 26th, at Muntham, Torquay, the wife of P. C. Gibson, M.D., of a daughter.

Langmaid.—On May 25th, at Southsea, the wife of Dr. F. Rodney Langmaid, of a son.

McLaggan.—On May 30th, 1934, at 27, Welbeck-street, to Elsa, wife of J. Douglas McLaggan, F.R.C.S.—a son.

Morland.—On May 27th, at Cook's Hill, Mundesley, the wife of Andrew Morland, M.D., of a son.

Owen.—On May 24th, the wife of Charles Langley Owen, F.R.C.S. Eng., of Tregony, Cornwall Gardens, Cliftonville, of a daughter.

Polson.—On May 24th, at the Imperial Nursing Home, Harrogate, the wife of Dr. Cyril Polson, of a daughter.

Ratcliffe.—On May 22nd, the wife of James Rudd Ratcliffe, F.R.C.S. Eng., of Derby, of a son.

MARRIAGES

Graham—Batson.—On May 24th, in London, C. I. Graham, F.R.C.S., to Evelyn Marjorie Batson, of Rodwell, Weymouth second daughter of the late Dr. and Mrs. W. L. Batson, of Dorking.

DEATHS

Cooke.—On May 23rd, at Alverthorpe, Ripley-road, Worthing, Dr. John Benson-Cooke, aged 82.

Fullerton.—On May 22nd, Andrew Fullerton, C.B., C.M.G., F.R.C.S.I., of University-square, Belfast.

Hurlbutt.—On May 25th, at Collingham-road, S.W., Spencer Hurlbutt, M.R.C.S., L.R.C.P.

Kauffmann.—On May 15th, after a very short illness, at his residence, Hermitage-road, Edgbaston, Birmingham, Otto Jackson Kauffmann, M.D., F.R.C.P., Emeritus Professor of Medicine, University of Birmingham, aged 71 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Kent and Canterbury Hospital.—It has been decided to rebuild this hospital with about 150 beds on a site at South Canterbury at a cost roughly estimated at £100,000, of which it is expected that £84,000 will be available by the end of this year. The scheme includes beds for paying patients and a nurses' home to accommodate the entire nursing staff; the nurses are at present "billeted all over the city." Dr. Harold Wacher describes the present out-patient department as "chaos" and the dental, bacteriological, and orthopædic departments as housed in "miserable buildings showing ominous signs of decay."

NOTES, COMMENTS, AND ABSTRACTS

A SURGICAL PILGRIMAGE TO ROME

By H. S. Souttar, C.B.E., F.R.C.S.
SURGEON TO THE LONDON HOSPITAL

It is always difficult to assess the value of an experience or to define precisely what it has taught us, and in nothing is this more striking than in a visit to a foreign clinic. We see a number of hospitals quite different from our own, and doctors working under conditions as foreign to us as are their countries, and one perhaps watches a series of operations and admires the dexterity and success with which they are performed. Perhaps one picks up a few ideas on organisation, or hints for an improved technique, but one comes away with a feeling that one has gained something of greater importance than such details as these, something indefinable and incommunicable which has made the journey well worth while.

This was undoubtedly true of a small party of Pilgrim Surgeons who left London one morning last February on a visit to Rome. Early on Monday morning, after 32 hours' travelling, we met Prof. R. Bastianelli at his private clinic in the Viale Regina Margherita. We were taken to his library surrounded by surgical journals in every language, and we were shown a series of perfect case records extending back over many years. We were introduced to the secretary-artist who keeps the records and makes coloured drawings of all the more important cases. The drawings were all of exceptional perfection and formed a fitting record of a splendid surgical technique. The clinic is the private property of Prof. Bastianelli, it contains 50 beds and is fitted with the most modern equipment in every direction. It is staffed by three assistants and a large nursing establishment.

Prof. Bastianelli performed an operation upon an old case of suppurative cholecystitis with perforation of the duodenum and colon. The case was one of great difficulty and the gall-bladder was removed with remarkable skill under perfect local anæsthesia. This was followed by a gastrectomy for duodenal ulcer. An interesting point in technique was the stripping of the vessels from the greater curvature and the separate ligature of the anterior and posterior groups. A great point was made of the actual removal of the ulcer, accomplished with some difficulty, since it had involved the pancreas. The duodenal stump was closed and a retrocolic Polya anastomosis performed. This operation also was under local anæsthesia.

Tuesday morning we spent at the Policlinico Umberto I with Prof. R. Alessandri. This enormous hospital with over 2000 beds was opened 35 years ago, and the writer actually saw it before it was opened. It was then intended to take 4000 patients, and it was rightly regarded as one of the medical wonders of the world, built on the pavilion system on a single corridor 900 metres in length. It was then thought that it would never be filled and the number of beds was curtailed, but so rapidly has Rome advanced that it is now considered quite inadequate to its needs and has been supplemented by several other large hospitals. We saw three operations performed by Prof. Alessandri under local or regional anæsthesia. The first was an exploration of the parathyroids in a case of spondylitis ossificans, on which disease Prof. Alessandri has done some interesting work. This was followed by a cholecystectomy under local anæsthesia, and a nephrectomy for a tuberculous kidney under extradural anæsthesia produced by the injection of 1 in 1000 solution of percaine in the upper lumbar region outside the dura.

After the operations we were taken to a fine lecture theatre where we were shown a series of cinematograph films illustrating points in operative technique. We were told that the university possesses a large stock of these films and that they are extensively used in teaching students.

On Wednesday morning we visited the Istituto Regina Helena, called the "House of Tumours," and devoted to the study of the causation and treatment of tumours of every kind. It is really a complete hospital with 250 beds arranged in small wards and private rooms. There is an X ray department complete in itself for early diagnosis and treatment, and both the hospital and its X ray department are equipped in a most lavish and up-to-date manner. Attached to this is a research institution with facilities for experimental research of every kind. The roof is devoted to animal houses, and one large room is specially equipped for culture of living tissues. Although the laboratories are already complete, the only appointment so far made is that of Prof. Bastianelli to the directorship. In the hospital itself we were specially impressed by the X ray department equipped with double diagnostic sets of the latest type, and with double treatment sets operating at 250 k.v.

From here we went on to the Ospedale di Littore where we met Prof. A. Chiasserini. We saw him perform an extraperitonal resection of the left lumbar sympathetic in which he obtained an admirable exposure through an oblique lateral incision, and a laparotomy for a duodenal ulcer. He afterwards showed us a large number of specimens of gastrectomy, an operation which he invariably performs for all duodenal as well as gastric ulcers. We saw several of his cases of recent date and were much impressed by the results.

In the evening we had the pleasure of entertaining at dinner a few of the leading medical men of Rome, when Prof. G. E. Gask, who was the leader of our party, gave a message of greeting from the President of the Royal College of Surgeons of England to Profs. Bastianelli and Alessandri, honorary Fellows of the College. Prof. Bastianelli replied in a charming speech, in which he congratulated the Pilgrims on having at last found in Rome a true object for their pilgrimage.

The Pilgrims returned full of enthusiasm for all that they had seen and for the kindness with which they had been received on every hand.

Looking back over 35 years to a former visit, I found Rome itself to show many changes. The beggars and the slums have gone and everywhere one sees evidences of a new life and of a new spirit. No city in the world can point to the memory of such a glorious past; may the future hold for her an equal prosperity.

A MUNICIPAL CHILDREN'S HOSPITAL

Ever since the supersession of the boards of guardians the county borough of Middlesbrough has been at work upon a comprehensive scheme of reorganisation of the town's hospital and kindred services. Among its inheritances from the guardians was the Broomlands (Children's) Hospital, then more than 30 years old, which it soon became evident could be made to serve its purpose efficiently only by a serious expenditure. There was, however, another and more promising building in the possession of the town council which it was decided to modernise and adapt as a children's hospital. This has now been done at a cost of £2500, and the new institution was opened last week. The exterior of the building is admittedly rather grim, and it might have been supposed that its first vicissitudes would make its conversion a matter of difficulty. Originally two buildings erected as children's homes, there was a surrounding high wall which did not make for cheerfulness. Presently the wall was demolished, and, going from one end of life to the other, the building became a home for aged women. After the war it was leased by the corporation from the guardians and turned into flats, but eventually the tenants jibbed at the high rents which, in the end, they refused to pay. Then the guardians used it as a hospital for midwifery and female medical cases until that body receded into history.

The adaptation has been skilfully accomplished, and the building now contains four ground-floor wards, two large and two small, which can be converted into open-air wards by opening the French windows, five small wards and a large one on the first floor with an operating theatre and the necessary accompaniments of a complete hospital on a small scale, including a plaster room and an operating theatre. The building looks out upon a lawn, and there is a veranda for camp beds that delicate children may obtain all the available sunlight and fresh air. The wards, which will accommodate 82 beds, are painted in varying pastel shades and have oak floors. An essential part of the hospital is a school with a fully qualified whole-time teacher who holds classes in the wards for cases of long duration. It is claimed that the hospital will substantially reduce the cost of administration, and it certainly appears to be a promising example of what can be done by the coördination of hospital activities.

PREVALENCE OF CONTRACEPTIVE METHODS

THE reports of the International Medical Group for the Investigation of Contraception take stock periodically of the progress of birth-control knowledge throughout the world. In the current issue, the fifth of the series,[1] the contributions treat of developments, both in the *technique* of contraception and in knowledge of the distribution of its practice, that have occurred in Great Britain, the United States, Denmark, and Russia since the publication of the previous report in 1931; and of the rise and overnight collapse of the birth-control movement in Germany within the same period.

Perhaps the most generally interesting, as it certainly is the most illuminating, contribution is the full summary by Dr. C. P. Blacker—who, as secretary to the Birth Control Investigation Committee, is responsible for the report—of three statistical studies which deal with the contraceptive practices of a group of English women (mainly middle-class), and of two groups of women in America, one belonging to the relatively intelligent and educable class that avails itself of the services of birth control clinics, the other a group of women who had been delivered of babies in maternity hospitals and belonged for the most part to the poorest and least literate elements of society. In the English group, a method of which the sheath was an important component was used more frequently than any other; coitus interruptus came next in frequency; the rubber cap next; and then quinine pessaries. The most striking contrast between the two American groups is in the fact that, whereas over 90 per cent. of the clinic group had previously used one or more contraceptive methods, only 30 per cent. of the poorer, less educated group had done so.

In the clinic group the most favoured previous method was coitus interruptus, and next in order of frequency were douching with a diversity of medicated solutions, the sheath, soluble pessaries, and sponges. The chief contraceptive devices of the maternity hospitals group were, in order of frequency, the sheath, douching with medicated solutions, coitus interruptus, and douching with plain water. Considering the economic level of this group, it is surprising that coitus interruptus (which costs nothing) did not come first in order of frequency, its prevalence—i.e., in 17·4 per cent. of the cases—being in fact lower than in any other English or American group that has formed the subject of a similar inquiry. Soluble pessaries were low and rubber pessaries even lower in the list, perhaps owing to the inflated retail prices of the former and the skill required for the correct application of the latter: but it is not improbable that women who adopted methods involving the use of these devices would be less likely than others of their social class to appear in the records of maternity hospitals. This latter explanation is certainly borne out by Dr. Hannah Stone's study of the contraceptive successes and failures of 2000 patients of the Maternal Health Centre, Newark, New Jersey, which tends to the conclusion that "if a woman scrupulously fulfils the instructions attaching to the use of the Dutch pessary combination, there will be about one chance in 100 of its failure in the course of a year, or approximately one chance in 5000 of its failing at each act of coitus." Similar results are recorded by the leading English clinics, wherein the proportion of failures is about 5 per cent.

One, at first sight, surprising fact brought out by Dr. Stone's statistical analysis is that douches of plain water have a higher record of successes than douches containing spermicidal substances. It seems probable that the effectiveness of post-coital douching as a contraceptive measure depends to some extent on a time-factor—varying inversely with the interval that is allowed to elapse between coitus and taking the douche. The greater success of plain water is thus explained by its being available at once, whereas the preparation of medicated solutions may result in the loss of valuable time.

PUBLIC SCHOOLS YEAR BOOK FOR 1934

THE forty-fifth issue of this year book—it was first issued in 1889, and became connected with the Headmasters' Conference in 1910—is something of a landmark, for it presents for the first time details of the leading preparatory schools; there is thus available under one cover official information regarding a large and important section of the national system of education. To avoid misunderstanding, however, the editors of the year book desire to make it clear that it does not purport to give information about all the public schools in the country but only those which are eligible for representation on the Headmasters' Conference. Besides this directory there is a large section dealing with careers in which parents, schoolmasters, and boys can find first-hand and trustworthy information about the navy, army, civil service, colonial services, and the various professions. Communications about the year book should be addressed to the Managing Editor, P.S.Y.B., 31, Museum-street, London, W.C. 1. The price is 10*s.* 6*d.*

BILHARZIAL APPENDICITIS

IT is now realised that in tropical medicine a great variety of affections of the vermiform appendix may be distinguished. There is undoubtedly a form of amœbic ulceration which may lead to perforation and this has been recognised in Egypt as well as in India and Malaya. Then again in malaria, and especially in the subtertian form, the appendix may be the seat of the pain due to blockage of the venules with sporulating parasites. The appendix, too, forms a resting-place for many intestinal worms; the roundworm may invade the lumen, as in the case recorded in our issue of Jan. 6th (p. 51) by Dr. H. E. S. Stiven, and the threadworm, oxyuris, is frequently found there also.

In bilharziasis the eggs of the parasite are very often deposited in the appendix and may give rise to a tumour of considerable size, exciting the symptoms of appendicitis, as has happened in many of the reported cases of infection with *Bilharzia japonica*. Interesting pathological specimens collected by the late A. R. Ferguson are to be seen in Cairo, and it appears that both species of bilharzia (*B. hæmatobia* and *B. mansoni*) can cause these tumours. Dr. Moh. Abdel Monem El Diwany (Jour. Egypt. Med. Assoc., March, 1934, p. 285) in describing the symptoms of this affection, shows that these do not differ much from the signs of chronic appendicitis. The tenderness over McBurney's point is not of much assistance except in the acute attack. Usually the appendix can be easily palpated and there is slight leucocytosis (10,000) with a definite increase of eosinophil cells. After operation treatment should be continued by means of intravenous injections of tartar emetic.

A MIXED BAG

Sir William Hodgson is to be congratulated not only on his eightieth birthday but also on the birthday present which he has received from his fellow-practitioners in Cheshire. "Fasciculus Cestriensis" is a collection of short articles mainly therapeutic and largely, but not entirely, written by general practitioners. A rough-and-ready technique for tracheotomy, the use of turnip-juice in whooping-cough, the cleansing of a coated tongue with fresh pineapple, the improvisation of a catheter, the treatment of lupus vulgaris with permanganate of potash and of alopecia areata with methylated chloroform and oil of cade, are only a few of the practical points dealt with in this fascinating book.

The general practitioner's therapeutic armamentarium is culled from divers sources. If he is humble and sensible he will learn from all with whom his work brings him in contact, from the consultant on the one hand to the "wise woman" on the other. Doubtless some of his knowledge is mere superstition and much of it unscientific. Being so often unable to carry out control experiments, he is a frequent victim to the fallacy of post-hoc propter-hoc. Nevertheless, it sometimes happens, especially in cases of chronic disease, that neither the text-book nor the consultant can help him and, being thrown on his own resources, he remembers John Hunter's dictum, "Don't think—try." In the course of a professional lifetime he must discover something of value to medicine, especially to therapeutics, and the "Fasciculus Cestriensis" proves it. Sir William Hodgson has inspired the Cheshire panel committee, ably backed up by the Cheshire doctors, to make an attempt to pool their collective wisdom.

It is an example which might well be followed by other counties.

RADIOTHERAPY IN TUBERCULOUS MENINGITIS

Two years ago Prof. Z. von Bókay, of Debreczen, in Hungary, reported the treatment of 17 cases of tuberculous meningitis with deep X rays (see The Lancet, 1932, i., 894). The diagnosis had been made by finding tubercle bacilli in the cerebro-spinal fluid or in an inoculated guinea-pig, and five recoveries were claimed—in children between 3 and 12 years of age. As the condition is almost always fatal under ordinary circumstances these findings aroused much interest and several attempts have been made to repeat the observations. M. Faberi and C. Fumi, from the institute of clinical pædiatrics of the University of Rome, review (Policlin., April 23rd, 1934, p. 608) the results obtained and add particulars of nine cases treated by themselves according to Bókay's technique. In all they give particulars of 29 cases (including several in which there was evidence of miliary dissemination) in which the diagnosis had been established and deep X ray therapy was employed. It is unfortunately only too easy to summarise the results obtained, since in every case the patient died, and in several of them it was thought that the course of the disease had if anything been accelerated by the remedy.

CONTROL OF EPIDEMICS IN CHINA

The reports for the year 1932 of the National Quarantine Service of China are to hand in a volume of some 330 pages, with many illustrations. While much of the detail concerns port sanitary workers only, the account of the cholera epidemic of 1932 in which some 94,000 cases occurred with 31,000 deaths is of considerable general interest. Among the facts disclosed is that in Shanghai the death-rate among Chinese (4221 cases) was 7·06 per cent., and among foreigners (75 cases), 26·6 per cent.—a difference attributed by the authors to early hospitalisation of the Chinese. In neighbouring war-stricken towns where no hospital facilities were available a fatality-rate of 44 per cent. is recorded (212 cases). Chapters are also included on an epidemic of small-pox in Amoy; on a new survey of plague in wild rodents; on a rat-flea survey of Shanghai; and on the present status of the leprosy question in China. The year was a very difficult one since the work was disorganised in Shanghai and the quarantine station was destroyed in the Japanese attack on the city. The Plague Prevention Service in Manchuria was driven south of the Great Wall when the Japanese occupied that province. Nevertheless, much valuable work seems to have been accomplished and it is admirably reported. The records are edited by Dr. Wu Lien-Teh (Tuck), director of the Service, and Dr. Wu Chang-Yao.

NEW PREPARATIONS

Minadex.—From the Glaxo Laboratories (Osnaburgh-street, London, W.) we have received a syrup having the following formula for each fluid ounce:—

	Grains.		Grains.
Ferr. et am. cit. (vir.)	14	Sod. glycerophos...	1/10th
Calc. glycerophos. ..	2	Mang. glycerophos.	1/25th
Pot. glycerophos. ..	1/5th	Cupr. sulph. ..	1/25th

The *content of vitamins A and D for each fluid ounce* are claimed to be higher than that in the same quantity of medicinal cod-liver oil. The well-known therapeutic action of iron and the other salts and the vitamin content lead the proprietors to allude to the preparation as a threefold tonic. The tonic properties are obvious, while the suggested dosage ranges from half a teaspoonful for little children up to two teaspoonfuls, according to age, for adults, but the wise direction is printed on the bottle that Minadex is to be given only as a physician directs.

Sagradol.—The Angier Chemical Co., Ltd. (86, Clerkenwell-road, London, E.C.), have put on the market a new remedy for constipation, a combination of mineral oil and cascara sagrada, and they believe that the blend, which has been difficult to obtain in perfect balance, is a stable product. The peristaltic action of cascara synchronising with the moistening and softening results of the oil ingested, lead to an easy purgation and there should be considerable demand for the preparation. Clinical evidence concerning patients suffering severely from constipation indicates that a soft and normal stool may be produced in stubborn conditions of the bowel where harsher cathartics have been ineffective. For this reason the preparation has been used successfully in the constipation of pregnancy.

CHILD MARRIAGE

Few will be able to read unmoved the graphic account of the evils of child marriage given by Miss Rathbone in a little book recently issued.[1] Some may disagree with the attribution of blame, and some may see little hope in the proposed remedies; but that the social customs of India inflict unnecessary suffering upon little girls is hardly to be doubted.

Miss Rathbone explains and describes the Joshi Report on Child Marriage and discusses the Sarda Act, the disastrous delay in putting it into operation, and its non-observance at the present time. She examines the Census Report, with the population and vital statistics of the men and women of India, and then suggests remedies.

One hundred out of every thousand girl wives are likely to die in childbirth in first or later pregnancies; and out of every 100,000 children born alive, 45,000 die before the age of five. The expectation of life in India for men is 38·96 years, and for women only 36·75. Facts like these, culled from the Census Report, the Joshi Report, and from a dozen other medical and official sources tell their own depressing story.

The author's object is to arouse concern and responsibility among British readers, and the presentation is so vivid that she is not likely to fail to achieve this aim.

ADDRESSES AND ORIGINAL ARTICLES

EXPERIMENTS ON MAN [*]

By J. Barcroft, C.B.E., M.A., F.R.S.
PROFESSOR OF PHYSIOLOGY, CAMBRIDGE UNIVERSITY

When I was honoured with an invitation to give the Stephen Paget memorial lecture, that invitation was coupled with a request that I should take as a subject "Experiments on Man," but, perhaps unfortunately, it was left to me to interpret that phrase. Two possible interpretations I have put on one side, the first is sociological; it would be possible under the title of experiments on man to treat of one of the most interesting and important types of experiment, that which subjects groups of persons to certain altered sociological conditions. Having regard, however, to the memory of Stephen Paget and to the particular cause to which he devoted his life, I conceive that in the present connexion some more individual type of experiment was in the minds of those who asked me to lecture. On the other hand, I could treat of experiments, such as the classical one of Fick and Wislicenus, which while extremely informing were quite unattended by any particular risk to the subjects, and indeed may have formed an entirely pleasurable excursion. I have in the main set such aside also, and for the same reason—namely, that Stephen Paget's devoted labours had to do with experiments which, though not necessarily painful, were conducted under an Act of Parliament designed to secure the conscience of the nation against the suggestion that it tolerates wanton cruelty within its borders. The researches of which I shall treat to-day are on men, but are such that they would have to be conducted under the Act 39 & 40 Vict. of 1876 were man regarded as being a "vertebrate" in the sense of that Act. And in particular I wish to treat of a certain aspect of this subject—namely, the answer to the following very legitimate and indeed necessary question, "Can the results of experiments carried out on animals be regarded as applicable to man?" Let me say that I am not concerned here with the ethical aspect of my subject.

Can the results of experiments performed on animals be regarded as applicable to man? If we are to adhere to precise language, we are under no suspicion of "beating about the bush" if we refuse to answer our question either with a direct "yes" or "no"—many most important questions are insusceptible of monosyllabic answers. The results of such experiments as can be performed on animals can, as a rule, be transferred to man, though not without reservations, and these vary with the nature of the experiments. It is our object to discuss these reservations.

I wish to preface my remarks by a word or two about the meaning of the word "certain." Little in this life is "certain" in the absolute sense. Your secretary asks me in March whether I will lecture to you on June 5th. I say, "I shall feel honoured." He says, "Are you 'certain' that day will suit?" I look in my book and I say "yes." He at a later date issues a notice stating that: "The Eighth Stephen Paget memorial lecture will be delivered by Prof. J. Barcroft on June 5th, 1934, in the School of Hygiene and Tropical Medicine. The chair will be taken by the President, the Rt. Hon. Lord Lamington," &c. Now none of these things are "certain" in the absolute sense. I may die; the chairman may be sent abroad on urgent public business. An earthquake may wreck the building; nevertheless the secretary is not guilty of inaccuracy; to qualify his statement would be but pedantry. We understand by "certain," in this connexion, something which is so certain that we may reasonably take action upon it. This question, like most other questions, is largely one of probabilities, and as such even a single experiment on an animal has a value. You take a draught by mistake from some bottle the contents of which had, so far as you knew, never previously passed human lips; your apprehension would be great in any case, but it would be much greater if you knew that a comparable dose of the contents of that bottle had killed a rabbit than if you knew that the material had been administered to the animal without any perceptible effect. The event might not justify you, nevertheless that confidence so far as it goes would be wholly reasonable. In expecting that the drug would not kill you because it did not kill the rabbit you would be using an uncertain weapon, but even so you would run no mean chance of hitting the target. The small amount of experimental knowledge yielded by a single experiment on an animal would have a value. To attain a higher degree of certainty the problem becomes one of narrowing the issue, of bringing the target ever nearer to the marksman until in the end the chance of a direct hit amounts as nearly as possible to a certainty. How far can this be done?

Objective Experiments

I will first take the case of relatively simple substances, for it was in the use of such that I, personally, found myself face to face with this problem in a form which admitted of no evasion. That approach had to do with the administration of simple chemical substances which in one way or other act on the relatively uncomplicated processes of living protoplasm. The most obvious way of narrowing the issue is to broaden the basis of experiment. You can learn something as I have said by experimenting on a single form of life, but the more various the species on which you experiment the less uncertain will be the extrapolation from animals to man. That would follow a mere consideration of the probabilities of the situation. But you can narrow the issue still further. If you find differences between different forms of life, and if you can ascertain the causes of these differences, and if you can place man, relatively to these causes, you have narrowed the issue considerably. For instance, in the category of simple chemical substances may be put such a protoplasmic poison as hydrocyanic acid. The mode of action of this drug, largely through the researches of Evans, of Keilin, and of Warburg, is now known; it prevents the oxidation processes of the body by destroying the action of the enzymes concerned; in the case of the higher vertebrates the essential failure is that of the activity of the respiratory centre. There is no reason to suppose that these essential processes of life in man differ materially from those of other mammals, and therefore it might be supposed that weight for weight the lethal dose of prussic acid would be of the same order throughout the warm-blooded animals. Fig. 1 shows a number of curves. They refer to the strength of prussic acid vapour in the air (ordinate) which proves fatal to various mammals in the times given in the abscissa.

---

[*] The eighth Stephen Paget memorial lecture, delivered on Tuesday, May 5th, 1934, at the annual general meeting of the Research Defence Society.

Similar curves have been drawn out for other mammalian species, great and small; they all fall within the limits of the area A B C D E F G. With so much information therefore it would seem extremely likely that somewhere within the area, or not far outside, the curve for man would fall. To take an example, if we are driven by circumstances to take action, and wish to know how long a man can survive a concentration of 0·6 milligramme hydrocyanic acid gas per litre, the answer is that he would be exceedingly unlikely to die if exposed for less than one minute and extremely unlikely to live if exposed for much more than 15 minutes. This answer we know to be correct so far as the inferior limit is concerned, for the matter was on one occasion put to the test by an experiment on man. The subject was in the gas for upwards of two minutes, at the end of which time he was still in possession of his faculties.

The limits of course are wide, and if we knew the reason why the dog and the mouse are so susceptible, while the monkey and the guinea-pig are so resistant—the monkey at one end of the scale and the guinea-pig at the other—we could probably place the toxicity of the gas for man within much more precise limits. Concerning the great susceptibility of the mouse there is nothing surprising. It would seem to follow a general law familiar to all physiologists, the mouse being very small passes a great deal of air through its lungs in a given time for the size of its little body. It therefore per gramme of mouse inhales a great deal of the gas. Now the mouse can only live if it destroys the prussic acid as fast as the gas is inhaled. There is no special reason to suppose that the power of a gramme of mouse to destroy prussic acid is greater than that of a gramme of a larger animal, the mouse therefore is killed in low concentrations of the gas.

The dog forms a more interesting study, it is more akin to man in size and quite of the same order as the monkey or the goat. Why is the dog so susceptible? The first point to emphasise is the special way in which the drug is administered—namely, by inhalation. The lethal dose is much the same for most mammals, including those mentioned when injected into the blood, but a given concentration when breathed produces widely different results, it is natural to ask this question. When the drug is injected intravenously he is not particularly susceptible. The question therefore arises—do the dog and the goat really inhale the same quantity of air weight for weight? We may reasonably suspect that they do not. When the animal is exposed to hydrocyanic acid the initial effect of that gas on the respiratory centre is one of stimulation. The dog is capable of a much greater and more sustained degree of activity than most other animals. He can run down almost anything and pre-eminently he can run down man, from which it may be inferred that the maximal total ventilation of which the dog is capable is for its size greater than in man. The reason why dog yields so quickly to an atmosphere of prussic acid is probably due to the power of his respiration; he takes a much larger quantity of the fatal gas; in short, he takes a bigger dose. Knowing these things the issue is much narrowed, and it might confidently be predicted not only that man would fall inside the limits which I have indicated, but that the gas would be much less powerful in its effect on man than on the dog, and that, again, is so because on the occasion of which I told you there was a dog in the lethal chamber with the man; at the termination of the experiment the dog was moribund.

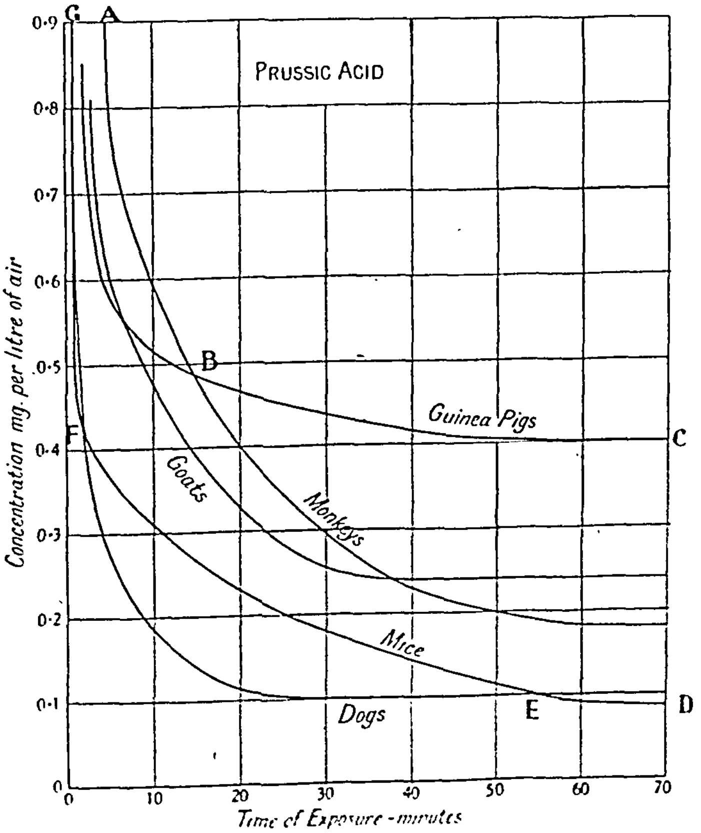

FIG. 1.—Concentration curves showing time of exposure to HCN, which produce 50 per cent. deaths.

I need not emphasise the practical importance of the problems. Prussic acid itself has come into use on a large scale for the decontamination of ships, and questions are constantly arising whether exposure to the gas can have been the cause of subsequent disability. Not only so but in the ever-increasing complication of industrial processes new dangers arise from the exposure of employees to unsuspected gases in the atmosphere, and in case of some unexplained death or illness questions arise at once—What fumes were in the air to which the victim had been exposed? Were they toxic? Can he have been exposed to them in sufficient concentration to account for his illness?

But not all gases met with in commerce offer so simple a problem as prussic acid—e.g., gases which irritate the lungs such as chlorine or phosgene offer a more complicated type of problem. They are both met with in commerce and about both the question arises, what concentrations can man tolerate? Is it possible without doing experiments on man to obtain information on the toxicity of irritant gases, and if so how reliable is that information?

Fig. 2 shows the concentrations of gas which ultimately prove fatal if the animals are exposed for the times stated. Here again, unless the man has some special property which animals have not, he is likely to fall within the general area occupied by the curves. The area is a very wide one.

Can we by considering the physiology of the animals narrow it? The apparent resistance of the rabbit and the goat can be explained; they have remarkable powers of holding their breath—faced with an irritant gas they can and do refuse to breathe it. As man has not this power the rabbit and the goat may be wiped off the picture. The remaining animals, and there are many more than those shown, form mostly a compact area. They are so diverse and the area so compact that the compactness can scarcely be due to chance and therefore unless man has some peculiarity he may be supposed to fall in this compact area. There is, however, one peculiarity of man which may affect the situation; irritant gases produce coughing in man. There are many quite harmless ways of producing a fit of coughing in which case the effect of coughing on the total ventilation may be measured.

Can we without doing an experiment on man give any information about the concentration of chlorine or phosgene in the air of a works which we would confidently describe as not being injurious to man? Such a question might arise in case an employee developed some lung trouble after exposure to an atmosphere which caused suspicion. Clearly we can answer it with a high degree of probability. The curves in Fig. 2 apply to deaths, but a similar series might be made out in which the time of exposure was plotted against the just perceptible lesion. There is no reason to suppose that a greater or less concentration of chlorine or phosgene would be required to produce a lesion in man than in animals generally and so, allowing a margin of safety, it would be possible to say, unless a man were exposed to such and such a concentration for such and such a time, he would be unlikely to be injured. This, of course, is not intended to weaken the practice of so designing plant as to have the air quite pure.

Experiments on Sensation

It seems clear that for experiments of simple type, the results of which are purely objective, a great deal of information may be obtained upon animals which can be transferred with considerable confidence to man. How far can experiments on animals yield correct information with regard to human sensation? The difficulties here are much greater and for two reasons. The first is that the various sensations are developed in very different degrees throughout the mammals including man; the second is the obvious difficulty of getting the animal to tell you what he feels. I take these difficulties one by one.

1. Concerning the unequal development of sensation, it is a commonplace that some sensations are ill-developed in man whilst others are highly developed. The sense of smell for instance is obviously very poorly developed in man as compared with very many animals. Yet, keeping still to the study of the respiratory passages, things in the air which are intensely irritating to man appear to have no effect or scarcely any effect upon animals. In such cases, of course, it is not possible to decide how much of such a substance must be in the air in order to produce irritation of a given degree of gravity. The recognised procedure is simple; the test must be made upon a human subject, but the subject is exposed first to a concentration of the gas in the air so dilute that he cannot feel it and gradually and in successive tests the concentration is increased until the required information is obtained. Of those who have exposed themselves to such tests I should doubt if there is now alive in this country anyone who has done so more freely than Prof. Raper of Manchester, who, during the war and in collaboration with the late Colonel Harrison and Major Ball, was responsible for that marvel of efficiency, the British Army respirator. I mention the matter, simple as it is, for the sake of establishing the general principle, which can be applied to more delicate and more complex problems—viz., that of working up from something which is harmless, to solve a problem about something which is the reverse.

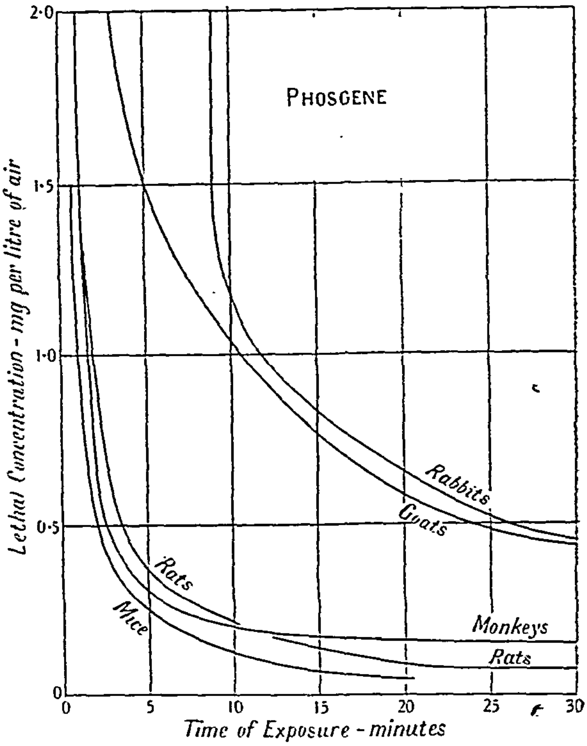

FIG. 2.—Concentration curves showing time of exposure to phosgene, which produce 50 per cent. of deaths within three days.

2. I said that there were obvious difficulties in getting an animal to tell you what he feels; note that I say *what* he feels not *whether* he feels. If an animal is in pain I am sure that a person versed in his language would know it. I doubt, for instance, the possibility of an animal in the Zoological Gardens experiencing real suffering without the fact being obvious to one of the trained attendants in that institution. To define exactly what is being felt is, however, a matter so difficult that even the most experienced experts do not always find it easy. The instance of such an experiment which first comes to my mind is the classical one in which Head and Rivers explored the sensations contingent on the cutting, and regeneration, of the nerve going to an area of skin on the forearm. It may be doubted whether a greater superstructure of theory was ever built upon a single experiment. The phenomena of sensation as they appeared to and were described by Head, the partner whose nerve was cut, shaped themselves into the theory of crude and delicate sensibility, as being quite distinct forms of sensation, a theory so intriguing that it soon became expanded, especially by Rivers; so that before his death it embraced not merely the phenomena of regenerating nerve and mental aberration, but a whole system of philosophy. Yet the tragedy of all this is that no

subsequent observer has found it possible in portraying his sensations to reproduce Head and Rivers' picture of epicritic and protopathic sensation. Three very serious researches have been carried out on this subject from different angles. The surgeons have done it in the persons of Trotter and Davies, the psychologist in the person of Boring, and the physiologist in that of Sharpey-Schafer. There is unanimity as between these observers on two points: first, that a single experiment of this type would not suffice even to teach them correctly to describe their sensations; secondly, that the description in no case supports the theory that crude and delicate sensations differ not only in degree but in kind. Not that Head and Rivers did not make a great advance. Of all who appreciate the step forward which they made I imagine those who appreciate it most are those whom it inspired to tread this same path. The theory of protopathic (crude) as different from epicritic (delicate) sensation awaits confirmation; meanwhile there remains the heroism and example of its founders, and if they did not reach finality it may at least be said of them in a preeminent degree "they have laboured and others have entered into their labour."

Experiments on the Higher Faculties

When the issue is that of testing the effect of this or that procedure on the higher faculties, it goes without saying that the subject tested must be man himself. You cannot test the minimum atmospheric pressure at which differential equations can be solved on mice. As an example of the sort of experiment I have in mind I recall one in which the problem was set by authorities who were interested in certain special problems of ventilation. I was asked how many persons could in an extreme case work in an unventilated room of a certain size. The first issue was this, if a certain number of people are in a closed room what is the essential factor which will reduce the quality of their work? In a small way it is the same problem as that of what killed the people in the Black Hole of Calcutta. History has always assumed that they died of asphyxia. Modern views of ventilation all point in a different direction—namely, that they died of heat stroke. If there is no through current and the amount of heat produced by persons in a room is greater than the walls of the room can carry away, the temperature of the inhabitants must rise, and in the extreme case fatally.

In the experiment in question a well-built basement room was chosen—the weather was hot and sultry with no movement in the air. Eighteen persons, of whom 13 did expert typewriting, spent from 8 A.M. till 4 P.M. in the room. All the chinks round the windows were made tight with paste and paper, the door and chimney were closed up, and there was as nearly as possible no ventilation. Fans were going and everything was blowing about. The circulating air evaporated the perspiration from our skins, which in turn condensed on the walls. For my part I made analyses of the room air from time to time while others carried out their prescribed tasks, mostly typewriting. All went well. On the next occasion with the same room, the same people, and approximately the same weather, the procedure was changed. The fans were abolished, but all unknown to the subjects I removed some of the window panes, so that although there was no perceptible movement in the air of the chamber, it was perfectly pure from the chemical point of view. The remarkable fact emerged that not only were the subjects more comfortable on the first day, but they did their work better, made fewer typographical errors, and so forth. It goes without saying that such experiments cannot be carried out on animals. We are in fact getting near limits which define the area in which experiments can be carried out at all. Somewhere near that limit is the whole territory of psychological tests—a subject on which I do not feel myself qualified to speak. I will only say this: that more than a dozen years ago I assayed to discover whether the mental abilities of a party of researchers who came with me to Peru were of their usually high standard when living at an altitude of 14,000–15,000 feet in the Andes; for this purpose I gave them what seemed to be suitable mental tests; the results when tabulated showed little or no falling off as compared with those yielded by the same persons doing the same tests at sea level. Yet the results of the tests were in a sense quite illusory, and obviously so—the work was as well done in the Andes as on the sea, but the effort of doing it and the concentration required were enormously greater. I expressed my disappointment at my failure to show up the mental deteriorations of my party, to Dr. Miles than whom I suppose there was no higher authority at that time on the value of mental tests, and I attributed my failure to my own inexperience. He very kindly said, "Barcroft, you are only where we all are." Since then much water has run underneath the bridge and psychological technique has made great strides, but speaking on this subject quite as a layman I suppose the difficulty of expressing in units which can be tabulated the amount which a given performance "takes out of the performer" is still a very real one.

Referring once more to Cerro de Pasco, I was told on high authority that an official of the Cerro de Pasco Copper Corporation would write a difficult report as cleverly at Cerro as in New York; but in New York he would do it in his stride, at Cerro it meant a subsequent trip down to the coast.

Disease

Disease in its simplest form—or at all events its simplest form from our point of view—may be no more than an upset of the balance of normal conditions in the body. A case in point would be the effects of hæmorrhage. The scheme of the hydrostatic arrangements in the human body is of the same character as in the higher animals; indeed, on broad lines there is singularly little difference throughout the mammals. The effects of deprivation of the blood can therefore be studied quite well on animals, and all the relevant information can be obtained. True it was an experiment on man which gave me a very broad hint that the volume of circulating blood could be adjusted within limits by contraction of the spleen. But the proof came entirely from animals, and more especially the very striking demonstration that quite a large volume of blood may be lost without prejudice to the actual amount of fluid in circulation. The amount being made good from the spleen and other depots. We may go further, and say that not only the effects of diminished blood volume can be ascertained by animal experiment but a great deal of information about the possible causes. The production of histamine in wounded tissue, its effects upon the permeability of the vessel walls, and so forth, all these have been discovered and demonstrated on animals. Man has no monopoly of histamine, nor does it act differently on human and feline tissues. It therefore happened that armed with a working knowledge of the effects of this material upon animals, Dale and Richards were at once able to recognise these same effects when they saw them in cases of wound shock. And if the last word has not been said on this subject, as Blalock would have us believe, it is not because man differs from other mammals in his reactions to loss of fluid from the vascular system.

But there are other and more complicated problems connected with the causation of disease. Let us turn to one or two presented by communicable disease. In general there are two problems: (1) what is the organism, or virus, which is the essential cause of the disease; and (2) what is the intermediate host, if any, by which it is communicated? If the disease is one to which a great many forms of life are susceptible the ground may be cleared by experiments upon them—such a case is plague. The typical symptoms of this devastating complaint are shown by mice, rats, and guinea-pigs. Rabbits[1] when inoculated, while rats, mice, monkeys when fed on cultures of plague bacilli acquire the disease and generally die with characteristic symptoms and lesions. Among these animals the rat is pre-eminent. Experiments with these have shown how the epidemic is transferred from rat to rat—namely, by the appropriate flea. Moreover, infected fleas when they bite other animals communicate disease. It is no wild exterpolation therefore to assume that the rat flea, if he is infected and bites a human being, will give the disease to him. If the human experiment had never been performed, there would have been a sufficient degree of certainty to warrant the declaration of a war against rats and their fleas, as the most promising campaign for the purpose of eliminating of plague among human beings.

Trench Fever.—But the disease may, unlike plague, be one which is not known to reproduce its symptoms in any form of animal life. Then the human experiment is imperative. The history of trench fever, which I quote from Major Byam,[2] is a case in point.

> "The question was, How did the germ leave the sick man and enter the healthy? Our recent work carried out for the War Office Trench Fever Research Committee has done a good deal to clear this mystery up. Several very gallant men came forward to help us in our task, and it is not too much to say that without such help we would have found out nothing, since experimental animals, which are all apparently resistant to trench fever infection, could not be used. These men volunteered to let us try to give them trench fever in any way we thought the disease might spread naturally in the field. The first two men to come forward were W. H. Cole and H. H. Edgeler, and to them great credit is due, as the work for which they offered themselves might, for all they knew, be productive of the most unpleasant consequences. Attempts were made to convey trench fever to these two men by allowing lice taken from the trench fever patients to feed on them. Nothing happened though the experiments were continued many weeks, but as we anxiously watched the men from day to day we were struck with the fact that they never scratched their skin where the lice had bitten. Was scratching an essential to infection? To test this possibility the skin of a new volunteer named D. Sullivan was on Feb. 5th, 1918, scratched by means of a needle, and the droppings of the lice feeding on Cole and Edgeler rubbed into it. A week later Sullivan developed trench fever, and as a result the usual method of transmitting the disease had been demonstrated, for we have repeated this and similar experiments many times with unfailing success. We have ourselves kept the droppings of lice for four months and then produced trench fever by introducing them into the skin of a healthy man which shows how truly infectious they are."

Yellow Fever.—Trench fever is not likely to kill the subject. But how does the case stand if, like yellow fever, the disease is one which apparently is almost certainly fatal? It has been claimed that 94 per cent. of the cases of yellow fever in the great epidemic in Rio in 1898 died. So we pass to yellow fever. When the subject became ripe for experimental work there was believed to be no experimental animal which could be used, for the simple reason that no animal was known to be capable of taking yellow fever. It was possible, however, to take advantage of the principle of working up from the harmless to the harmful, because there are numerous strains of yellow fever. If I may quote from the account given by Prof. Boyce of the work of the American Commission:

> "Finlay found that in 18 per cent. of his inoculation experiments there resulted a very benign form of yellow fever." Of these Case V. was one.
>
> "Case VI.—C. W., American, non-immune, aged 27, with his full consent was at 9.30 A.M., Jan. 31st, bitten by two of the three mosquitos that had been applied to . . . Case V. The interval that elapsed since their contamination was therefore 51 days." The subject obviously showed characteristic symptoms of yellow fever in three or four days. Convalescence was rapid.

Roughly then let me sum up: purely objective experiments do not as a rule demand the use of man; in a great many cases the relevant information can be obtained on animals. Experiments on sensation and on mental performance must usually be carried out on man himself. As regards the communication of disease, if animals show symptoms of the malady they can be used at all events to clear the ground. If they do not, resort must be had to the human experiment.

Conclusion

The considerations with which I opened this discussion brought back to me some recollections of the Great War. But a greater war is constantly being waged. It becomes dramatic when nations clash or when capitals are wiped out as was Rio by yellow fever. The dramatic element is due to the concentration of the fatalities in a small area, but disease is waging war to-day against mankind; less dramatically because its victims are diffuse in space, but no less certainly.

The proof that plague could be communicated to men was according to the text-book statement first supplied by Whyte, who injected himself with blood taken from a plague patient. I leave it to the judgment and conscience of my hearers to decide whether if to-day the matter could be settled with a high degree of certainty on rats, marmots, monkeys, and the like, such an act in any case one heroism would not verge on unjustifiable suicide?

The second instance quoted was injection of the disease into a condemned criminal. Having regard to the great number of experiments which usually are essential to the proof of anything, having regard to the paucity of condemned criminals, and having regard to the obvious abuses to which such a course is open, I again leave it to your judgment whether, if the relevant information can be acquired from animal experimentation, we should have recourse to the use of criminals. Personally I am against the use of criminals.

The third instance quoted was a deplorable accident in Vienna in which workers in some unaccountable way became infected from the germs of a culture.

A Pledge

I do not leave it to your judgment whether in the face of death around us we are to fold our hands and wait for accident to enlighten us. We of the

[2] Quoted from "Lice and their Menace to War," London, 1929. Chapter XI. written by Major Byam, R.A.M.C., p. 126.

Research Defence Society are pledged to the combat; we believe we have open minds; we believe that research is a most potent weapon, therefore we are pledged to research; we are pledged to certain methods of research—namely, animal experimentation—because we think that many problems can be solved most rapidly and most humanely by that method; but we welcome no less any other method which will be of use, any other weapon with which the war may be waged. We welcome criticism, but we judge it according to its constructive value. With the policy of waiting for the illuminating accident, with the policy of folding of the hands, with the policy of wrapping the talent in a napkin, we have nothing to do, but all legitimate methods, all useful criticism we welcome "so that by all means we may save some."

THE RÔLE OF THE LIVER IN THE METABOLISM OF CARBOHYDRATE AND FAT *

By C. H. Best, M.D., D.Sc. Lond.,
F.R.C.P. Canada
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF TORONTO

II.—THE LIVER AND CARBOHYDRATE METABOLISM

It was Claude Bernard who first appreciated the significant fact that the liver may provide sugar for the body. He regarded liver glycogen not only as a store of carbohydrate, but also considered the possibility that the liver might secrete this material in much the same way as we now believe other organs do their internal secretions. Because of the relative ease with which changes in liver glycogen may be studied, a great deal of attention has been given to this substance and perhaps not enough to the conditions which govern the rate of discharge of sugar from the liver. There is no room for doubt that the amount of glycogen and the output of sugar may sometimes be closely related, but these factors are not as interdependent as is often assumed. To a reviewer who entertains the idea that evidence will be forthcoming that sugar is made from fatty acids in the liver under certain circumstances, the discussion of gluconeogenesis at the present time is particularly unsatisfactory. Furthermore, nitrogen excretion as an index of sugar formation from protein leaves much to be desired. The difference between the sugar content of the blood of the hepatic vein and that of the hepatic artery and portal vein, which is not accounted for by change in liver glycogen, dextrose, or lactic acid, is the only reliable index of the rate of gluconeogenesis taking place in this organ.

Insulin and Gluconeogenesis

The evidence that there is an excessive sugar production by the liver after the removal of the pancreas is quite satisfactory, and since insulin completely corrects this abnormal condition there are good grounds for the belief that it inhibits gluconeogenesis in the diabetic. The end-results of insulin in the diabetic organism could be adequately explained on the hypothesis that insulin restored the ability of tissues to utilise dextrose, but, as I mentioned in the previous lecture, this property does not disappear after pancreatectomy.

Laufberger suggested inhibition of gluconeogenesis as a complete explanation of the action of insulin in the normal animal. The well-established effect on muscle glycogen proves that this is not the case. The probability that inhibition of gluconeogenesis plays a part in the action of an excess of insulin was stressed by Lesser and his colleagues and by Best, Dale, Hoet, and Marks.[1] As Cori [2] has pointed out, there are several series of experiments the results of which can best be interpreted on this ground (Issekutz; Macleod, Noble and O'Brien; Sahyun and Luck; Cori, Cori, and Buchwald). The finding that in unanæsthetised animals the hepatic vein blood contains less sugar when an excess of insulin is provided, and the less satisfactory evidence that this fall precedes the decrease in systemic blood-sugar, is very significant. This work has been conducted on adult rabbits and dogs in which an excess of insulin produces a fall of liver glycogen and free sugar. The lactate content may be approximately constant (Cori, Cori, and Goltz; Kotschneff [3]; Molitor and Pollak). These points are so important that repeated confirmation with certain extensions and possibly improvements in the experimental technique is desirable, but we may regard the evidence, at present available, for inhibition of gluconeogenesis in the normal animal by an excess of insulin as reasonably satisfactory.

Liver Glycogen

Our attention is much more frequently focused on glycogen. A convenient way of discussing liver glycogen in brief space may be to consider the formation and breakdown of this substance in diabetic and in normal animals.

LIVER GLYCOGEN IN DIABETIC ANIMALS WITHOUT INSULIN

Minkowski could detect no glycogen formation in the liver of a depancreatised dog when dextrose was provided, but reported positive results with fructose. Cruikshank in 1912 did not confirm this finding with fructose, but the livers he used were obtained from animals from which heart-lung preparations had been made. Paulesco found just under 3 per cent. of glycogen in the liver of a depancreatised dog after the oral administration of sucrose or glucose plus fructose. Banting, Best, Collip, Macleod, and Noble found 1·3 per cent. in the liver of one dog to which very large amounts of sucrose had been given. Bollman and Mann [4] have recently reported a transient retention of ingested fructose in diabetic dogs. This may be due to glycogen formation, which Cori has shown to be particularly rapid in the normal animal when this sugar is provided. There is no convincing evidence that the diabetic is able to burn fructose better than dextrose. Bodo, Tui, and Farber, and Major and Mann, have demonstrated a definite accumulation of glycogen in depancreatised dogs after the intravenous administration of dextrose. The previous work was open to several objections, which are successfully met in the recently reported studies. Major and Mann used dogs which had been treated with insulin immediately after the removal of the pancreas. Insulin injections were discontinued for a period of five days before the experiment. On the fifth day glucose was infused for from 10 to 12 hours. In a convincing number of the animals used, the deposition of glycogen was approximately 1 per cent. greater than that of control dogs. It is thus established that the depancreatised animal is able to store glycogen in the liver in the apparent absence

---

* Three lectures delivered for the University of London at University College on Jan. 11th, 15th, and 18th. Lecture III. will appear in a forthcoming issue.

of insulin, and under these circumstances we must look upon this process as proceeding at a slow rate (possibly by reversal of the action of glycogenase). The blood-sugar must have been very high in these experiments. There is no evidence that even a trace of insulin is present under these conditions, but the possibility that cells cling tenaciously to the last few molecules cannot be completely ignored. In the presence of insulin the rate of glycogen formation is, of course, greatly accelerated in both liver and muscle. Under the usual conditions in depancreatised dogs not receiving insulin, liver glycogen is at a very low level. In the decapitated cat some 20 hours after removal of the pancreas no recovery of liver glycogen is demonstrable. When the pancreas is present this process proceeds with considerable speed (Evans, Murphy, and Young).[5]

LIVER GLYCOGEN IN DEPANCREATISED DOGS WITH INSULIN

In 1923 Banting, Best, Collip, Macleod, and Noble found a very large deposition of glycogen in fed depancreatised dogs which received insulin. These results, which have been amply confirmed, established only that the accumulation of glycogen was an end-result which was observed some 48 hours after the insulin administration had been commenced. Quite recently Bodo and Neuwirth have shown that the increase of liver glycogen following the administration of glucose and insulin begins practically immediately, and the accumulation is apparently continuous. Hédon and Cori independently demonstrated a rise in liver glycogen in the fasting depancreatised dog after the administration of insulin. Cori found similar results in cats.

BREAKDOWN IN LIVER GLYCOGEN IN DEPANCREATISED ANIMALS

The rapid decrease in liver glycogen after removal of the pancreas requires no new comment. Adrenaline accelerates this process. The breakdown of hepatic glycogen in depancreatised animals receiving a constant amount of insulin has not been extensively studied. It is probable that the process proceeds very much as in the normal animal. There is an opportunity for further work in this field, however, because it would be interesting to determine to what extent, if any, the action of adrenaline on the liver glycogen of normal animals is due to changes in the rate and amount of insulin liberated from the pancreas. Small laboratory animals in which complete pancreatectomy can be readily performed are not easily available, but C. N. H. Long informs me that kittens have provided useful preparations.

The inter-relationship of the adrenal medulla and the pancreas is so well established that it may now be regarded as the duty of the experimenter who uses insulin to study, at the very least, suprarenalectomised animals before attributing the effect produced to a direct action of the antidiabetic substance and to study depancreatised animals as a part of an investigation of adrenaline action on carbohydrate metabolism. When we follow this idea to a logical conclusion the necessity of eliminating other glands of internal secretion and the need for studies of perfused organs under physiological conditions becomes increasingly apparent.

LIVER GLYCOGEN IN NORMAL ANIMALS

In normal animals very convincing evidence has been obtained by Cori and others that many different sugars give rise to glycogen in the liver—glucose, fructose, galactose, mannose, and arabinose. Xylose and the methyl pentose rhamnose do not increase liver glycogen when fed in a manner similar to the other sugars. Some of the amino-acids may provide a source of liver glycogen, but results obtained on diabetics cannot be transferred without modification to normal animals (Hodgson).[6] Glycerol is effective. One of the most interesting of the three carbon compounds is, of course, lactic acid. The dextrorotary lactic acid particularly has been found to form glycogen with great rapidity. Lactic acid formed in muscular exercise (Himwich; Long and Grant) may result in an increased liver glycogen. This aspect of the subject has been frequently reviewed. Drury and Salter [7] have recently shown that many derivatives of glucose which form glucose or glycogen readily in the intact animal fail to benefit the dehepatised rabbit. These results and those previously obtained by Mann and Magath emphasise the importance of the liver in the conversion of even very simple glucose derivatives into a form in which they are utilisable.

Since we may believe that none of these substances mentioned deposit liver glycogen in more than small quantities in depancreatised animals without insulin, *we must attribute this formation in normal animals in large part to the effect of insulin.*

Yet in 1923 McCormick and Macleod, using rabbits, and Dudley and Marrian, using mice, found a definite decrease in liver glycogen in fed or fasted animals when insulin was administered. In 1929 Cori and Cori found that when the blood-sugar levels in two groups of rats was maintained approximately the same by supplying more sugar to those who received insulin, deposition of the liver glycogen was of the same order in each group. Bodo and Neuwirth, working on normal dogs under morphine-chloralose anæsthesia, found that the glycogen storage in the liver which occurred with sugar alone was decreased when small amounts of insulin were given. Larger amounts of insulin produced a decrease in liver glycogen. This breakdown in liver glycogen was not due to hypoglycæmia, which has been shown in a convincing manner to be accompanied by liberation of adrenaline (Cannon; Houssay).

Before we assign to insulin two antagonistic rôles in the normal animal with regard to liver glycogen, let us examine other experimental results.

The experiments to which we have referred suggest that insulin and glucose given to a normal animal never result in a greater deposition of liver glycogen than would be produced by the sugar alone, that is, that the sugar liberates an optimal amount of insulin from the animal's own pancreas. There are, however, exceptions to these results. Deposition of liver glycogen was reported from Lesser's laboratory to be somewhat increased in the livers of mice when insulin as well as sugar was provided. Collazo, Händel, and Rubino fasted normal guinea-pigs for 18 hours and then administered glucose by stomach-tube. The animals which received insulin *after* the sugar had a greater content of liver glycogen than those which received the sugar alone. In 1929 Goldblatt [8] was able to show that exogenous insulin resulted in an increase of liver glycogen in the fasting young rabbit. This result has been confirmed by Sahyun and Luck, Corkill, and Bischoff and Long, and is the most notable and consistently recorded instance of increase in liver glycogen in the normal animal after insulin administration.

In view of the fact that the usual effect of an excess of insulin in most species is a decrease in liver glycogen, the question arises whether or not this action of insulin in young rabbits is a direct one. All of these workers, including Goldblatt, have shown that adrenaline injections may cause an increase in liver glycogen in these young animals, and it may be asked whether or not the insulin effect is due to a participation of the adrenal or one of the other glands, the secretion from which affects carbohydrate metabolism.

When the pituitary gland has been removed from these young rabbits insulin fails to produce deposition of liver glycogen (Corkill, Marks and White),[9] and I believe that preliminary experiments from the same laboratory conducted by Corkill and Cope indicate that the effect is not seen in suprarenalectomised young rabbits. Adrenaline seems a much more likely intermediary in this action of insulin than a pituitary hormone. In any case it appears unlikely that it will be necessary to consider this effect on young rabbits as a direct action of insulin.

The possibility must also be considered that the depletion of liver glycogen after injection of insulin observed in most species which have been studied is attributable to liberation of adrenaline which, as we will see later, may cause either an increase or a decrease in liver glycogen. There are difficulties in the way of accepting this conclusion. In 1927, Cori and Cori, and in the same year Artundo, found a decrease in liver glycogen in adrenalectomised rats which had received insulin. We cannot, therefore, under certain circumstances, hold the adrenal responsible for the decrease in liver glycogen so commonly observed after insulin. (It must not be forgotten, however, that the adrenal medulla may normally participate in this process.) This action of insulin may, however, be exerted only in part directly on the liver. We should not lose sight of the fact that under physiological conditions the action of insulin seems to be the storage of glycogen in the liver, and I still find it difficult to believe that experiments in which the amount of insulin present is increased only very slightly over that available from the pancreas will not reveal an increase in liver glycogen in species other than young rabbits or kittens. This plan has as yet yielded no success using rats, but samples should perhaps be taken earlier. The presence of large amounts of glycogen in the normal liver is, after all, due in large part to the presence of the pancreas. No one has ever noted a hyperglycæmia to which physiological significance can be attached after the administration of insulin. The decrease of liver glycogen may be secondary to the demand for sugar to form muscle glycogen, or for oxidation, and the failure of deposition of liver glycogen may be accentuated by the *decreased ability of the liver to produce dextrose under these conditions.* Deposition of muscle glycogen is so greatly accelerated (Best, Hoet, and Marks) by the presence of an excess of insulin that this process may take preference over a similar one which under normal conditions is also being encouraged in the liver. There may be some mechanism by which this preference is secured which does not involve hypoglycæmia or liberation of adrenaline. This conception may be expressed in other words; there is no evidence that insulin causes, by direct action on the liver, breakdown of glycogen. When the supply of dextrose is adequate liver glycogen is deposited; when insulin is present in excess, less of the sugar may be available for deposition as liver glycogen than when the concentration of the anti-diabetic hormone is lower. The evidence also suggests that the excess of insulin decreases the supply of dextrose by inhibiting its manufacture within the liver. This may result in a lowered glucose "tension" in the cells where liver glycogen is made. If no sugar is being manufactured in the liver and sugar is not administered, one might expect the glucose "tension" to be lower than that required for glycogen synthesis. Liver glycogen may be formed from lactic acid, so it is not established that the "tension" of dextrose is always an index of the amount of material available for synthesis.

ADRENALINE AND LIVER GLYCOGEN

In this discussion we have assumed that adrenaline can cause either breakdown or storage of liver glycogen. There is no doubt that the action of adrenaline is to accelerate the breakdown, but this is not the only effect of this substance.

In 1909 Pollak demonstrated a fall in muscle glycogen and an increase in liver glycogen in starved adult rabbits which were given rather large doses of adrenaline. More recently Cori has provided a more convincing demonstration of this phenomenon, and it appears likely that this is one of the usual physiological rôles of adrenaline. Whether a fall or a rise in liver glycogen is noted, depends on the time of sampling after the adrenaline injection (Luck and Sahyun). A fall is first observed, but the position is later reversed when lactic acid from muscle is built up into glycogen in the liver. Dextrose formed from the lactic acid may be responsible in part for the observed hyperglycæmia. It is only in the animal with intact pancreas that lactate from muscle has been shown to be formed into liver glycogen. This process, which may or may not proceed via dextrose, may be found to take place slowly in the apparent absence of insulin. It is interesting in this connexion to note that after adrenalectomy the recovery of liver glycogen in decapitated cats is accelerated (Evans, Tsai, and Young).

In discussing the hyperglycæmia produced by adrenaline one must consider breakdown of liver glycogen, the supply of lactate from muscle, and the still very debatable question of inhibition of carbohydrate oxidation. If adrenaline were secreted at an increased rate for a short time, one might expect first a decrease in liver glycogen and a hyperglycæmia, a fall in muscle glycogen, and an increase in blood lactate. Some of the lactate may be converted into dextrose, and insulin already available or liberated in response to the hyperglycæmia will facilitate the formation of liver glycogen. Under these circumstances there is presumably no excess of insulin.

INFLUENCE OF OTHER HORMONES

Thyroid.—In 1913 Kramer and Krause, 1924 Kusiyama, and in the same year Burn and Marks showed that liver glycogen could be reduced by repeated administration of thyroid extract. This effect on liver glycogen may be due to an increased activity of the thoracic autonomic nerve-fibres, with possibly liberation of "sympathin" in the liver, or may be in part due to the greater demand of apparently a variety of tissues for oxidisable material. There is, of course, evidence that the adrenals are made more active by thyroxine administration. The interesting work of Burn and Marks on the change in the response of animals to insulin and adrenaline as thyroid feeding is continued, and the correlation of these effects with the state of the liver glycogen, have been reviewed frequently. Interest in the effects of thyroxine on liver glycogen has been increased by the results of the recent work on the thyroid-stimulating hormone of the anterior pituitary. Eitel and Loeser[10] reported that injection of anterior pituitary extracts caused lowering of liver glycogen in normal but not in thyroidectomised guinea-pigs. The time relationships of the action of these extracts in the normal animals was similar to that which holds for thyroxine. It would, however, be unwise to conclude at the present time that the anterior pituitary may affect liver glycogen only through its thyrotropic hormone. As we will see later the diabetogenic fraction may exert an effect directly on the liver.

Pituitary extract.—It is perhaps unnecessary at the present time to consider the rôle of pituitary extract (vasopressin or oxytocin ?), since the balance of conflicting evidence suggests that this substance acts through liberation of adrenaline.

Adrenal cortex.—Numerous reports have been published recently on the rôle of the adrenal cortical hormone in carbohydrate metabolism. After double adrenalectomy in cats the carbohydrate reserves of the liver and muscles are depleted and there may be definite hypoglycæmia (Britton and Silvette).[11] This situation is corrected by providing the cortical hormone and glucose, but the effect is apparently not secured when glucose alone is given. This derangement of carbohydrate metabolism is not observed in some other species after suprarenalectomy, but Britton's recent work has added very necessary support to his contention that, in certain species, a disturbance of carbohydrate metabolism is one of the fundamental effects of cortical deficiency. Hypoglycæmia is, of course, observed in some cases of Addison's disease. It is certain that the next few years will bring us a great deal of new information concerning the effects of the hormone of the adrenal cortex on carbohydrate metabolism. There are many interesting experiments to be performed in adrenalectomised animals maintained by the cortical extract.

The Anterior Pituitary and Carbohydrate Metabolism in the Liver

In view of the signal importance of the work on the relationship of the anterior pituitary gland to carbohydrate metabolism which has been accumulating during the past seven or eight years, a short review will be given here.

The abnormalities in carbohydrate metabolism associated with acromegaly of long standing or with various pituitary tumours need not be discussed. The interesting new physiological work on carbohydrate metabolism might be dated from any one of many starting points. In 1908 Borchardt found that the extract of the posterior lobe of the pituitary raises blood-sugar. In 1911 Cushing observed that pituitary deficiency was accompanied by an increased carbohydrate tolerance. After insulin became available Burn demonstrated an antagonism between "pituitrin" and insulin, and several groups of workers showed that animals were more sensitive to insulin after removal of the pituitary body (Olmsted; Geiling). Attention was focused on the posterior pituitary. The interesting work on the relationship of the pituitary to carbohydrate metabolism conducted in Houssay's department during the last eight years began with the idea that the secretion from the posterior lobe counteracted some of the effects of insulin. Houssay and Magenta[12] presented very convincing evidence, in confirmation of the work quoted above, that hypophysectomised dogs are much more susceptible to insulin than normal animals. Houssay and Potick[13] removed the anterior lobes of the pituitary from toads with the production of hypoglycæmia and increased susceptibility to insulin, and subsequently Houssay and Biasotti[14] found no marked diabetes after complete pancreatectomy in these hypophysectomised animals. A graft of the glandular (anterior lobe) protects them against insulin, while a transplanted posterior lobe does not have this effect. Biasotti and Houssay report that hypophysectomised dogs may exhibit severe hypoglycæmia spontaneously, that they always do after a prolonged fast or injections of phloridzin, and that in some cases very low blood-sugar may be observed even after complete removal of the pancreas. This very striking finding that diabetes is absent or very mild in completely depancreatised dogs from which the pituitary gland has been removed has been confirmed by Regan and Barnes, by Soskin (personal communication), and D'Armour and Keller.[15] The longest survival period reported is six months, but many of these animals may have lived much longer by this time. Sugar and acetone bodies excretion (Rietti) in depancreatised or phloridzinised dogs which have lost their pituitary glands is much less than in otherwise comparable animals with the pituitary intact. Biasotti and Houssay seem to provide good evidence for the suggestion that it is a function of the anterior pituitary to regulate sugar formation from protein and possibly from fat or, in other words, that gluconeogenesis is greatly decreased in the absence of the anterior pituitary. In partially hypophysectomised animals the basal metabolic rate is low (Daggs and Eaton), but according to these workers and to Houssay there is no perceptible change in specific dynamic action of protein. The blood-sugar may be approximately normal and the usual type of carbohydrate tolerance curve may in some animals give normal figures.

Corkill, Marks, and White[8] using rabbits as test animals have recently confirmed many of Houssay's findings in toads and dogs and have extended them in some directions. Hypophysectomised rabbits are very susceptible to insulin and the hypoglycæmia is not easily relieved by adrenaline or vasopressin. Adrenaline is usually less effective in raising blood-sugar in these preparations and the suggestion is made that the glycogen reserves are not readily mobilisable after removal of the pituitary.

ANTERIOR LOBE EXTRACTS

The effects of extracts of the anterior pituitary may now be considered.

In 1926 Johns, O'Mulvenny, Potts and Laughton reported the production of hyperglycæmia in normal dogs which received "protein free" extracts of this gland. Houssay and Pottick found definite diabetogenic effects in toads. Evans, Meyer, Simpson, and Reichert produced diabetes of moderate severity in some, but not all, of their dogs which received daily injections of an alkaline aqueous extract prepared from beef anterior pituitary glands. This work was confirmed and extended by Houssay, Biasotti, and Rietti[16] who, using an alkaline extract of the anterior lobes, were able to produce hyperglycæmia, glycosuria, and acetonuria in normal dogs and rats, in partially depancreatised dogs, and in hypophysectomised, depancreatised dogs. Evans, in 1933, using normal dogs found lipæmia and hyperglycæmia. It is important to note that although pancreatic diabetes is somewhat modified by thyroidectomy in many species, the course of the condition in dogs after this operation is rapid (Yriart). It appears very unlikely on this ground that the anterior pituitary exerts its effect on gluconeogenesis through its thyrotropic principle. Furthermore, Houssay and Biasotti[17] have recently reported that hypophysectomy inhibits pancreatic diabetes in toads after removal of the suprarenals or thyroid. Transplantation of the glandular lobe exerts its diabetogenic effect in the absence of the adrenals or thyroid. While in these experiments both adrenals and thyroid were not removed in the same animal there seems little doubt that the diabetogenic effect was exerted directly on the liver. Campos, Curutchet, and Lanari[18] could not demonstrate the diabetogenic action of anterior lobe extracts in dehepatised toads.

While it is well established that removal of the adrenal medulla or interruption of thoracic autonomic nerve impulses increases the susceptibility of the animal to insulin, the evidence at present suggests that the substance in the anterior pituitary which affects the adrenal causes hypertrophy or prevents the atrophy of only the cortical tissue (Smith).

Anterior Pituitary and Fat Metabolism in the Liver

In 1930 Burn and Ling found that alkaline extracts of the anterior pituitary increased the acetone body excretion in rats, and in 1931 Anselmino and Hoffmann reported an increase in the acetone bodies of rats' blood after the injection of an extract of the anterior pituitary. These workers suggest that a rise in acetone bodies may be produced with these extracts without causing a hyperglycæmia. This work of Anselmino and Hoffmann has been confirmed in large part by Magistris[19] and the rise in acetone bodies has been noted in my laboratory by Mr. J. Campbell. Magistris has studied the increase in the acetone body

When the pituitary gland has been removed from these young rabbits insulin fails to produce deposition of liver glycogen (Corkill, Marks and White),[9] and I believe that preliminary experiments from the same laboratory conducted by Corkill and Cope indicate that the effect is not seen in suprarenalectomised young rabbits. Adrenaline seems a much more likely intermediary in this action of insulin than a pituitary hormone. In any case it appears unlikely that it will be necessary to consider this effect on young rabbits as a direct action of insulin.

The possibility must also be considered that the depletion of liver glycogen after injection of insulin observed in most species which have been studied is attributable to liberation of adrenaline which, as we will see later, may cause either an increase or a decrease in liver glycogen. There are difficulties in the way of accepting this conclusion. In 1927, Cori and Cori, and in the same year Artundo, found a decrease in liver glycogen in adrenalectomised rats which had received insulin. We cannot, therefore, under certain circumstances, hold the adrenal responsible for the decrease in liver glycogen so commonly observed after insulin. (It must not be forgotten, however, that the adrenal medulla may normally participate in this process.) This action of insulin may, however, be exerted only in part directly on the liver. We should not lose sight of the fact that under physiological conditions the action of insulin seems to be the storage of glycogen in the liver, and I still find it difficult to believe that experiments in which the amount of insulin present is increased only very slightly over that available from the pancreas will not reveal an increase in liver glycogen in species other than young rabbits or kittens. This plan has as yet yielded no success using rats, but samples should perhaps be taken earlier. The presence of large amounts of glycogen in the normal liver is, after all, due in large part to the presence of the pancreas. No one has ever noted a hyperglycæmia to which physiological significance can be attached after the administration of insulin. The decrease of liver glycogen may be secondary to the demand for sugar to form muscle glycogen, or for oxidation, and the failure of deposition of liver glycogen may be accentuated by the *decreased ability of the liver to produce dextrose under these conditions.* Deposition of muscle glycogen is so greatly accelerated (Best, Hoet, and Marks) by the presence of an excess of insulin that this process may take preference over a similar one which under normal conditions is also being encouraged in the liver. There may be some mechanism by which this preference is secured which does not involve hypoglycæmia or liberation of adrenaline. This conception may be expressed in other words; there is no evidence that insulin causes, by direct action on the liver, breakdown of glycogen. When the supply of dextrose is adequate liver glycogen is deposited; when insulin is present in excess, less of the sugar may be available for deposition as liver glycogen than when the concentration of the anti-diabetic hormone is lower. The evidence also suggests that the excess of insulin decreases the supply of dextrose by inhibiting its manufacture within the liver. This may result in a lowered glucose "tension" in the cells where liver glycogen is made. If no sugar is being manufactured in the liver and sugar is not administered, one might expect the glucose "tension" to be lower than that required for glycogen synthesis. Liver glycogen may be formed from lactic acid, so it is not established that the "tension" of dextrose is always an index of the amount of material available for synthesis.

ADRENALINE AND LIVER GLYCOGEN

In this discussion we have assumed that adrenaline can cause either breakdown or storage of liver glycogen. There is no doubt that the action of adrenaline is to accelerate the breakdown, but this is not the only effect of this substance.

In 1909 Pollak demonstrated a fall in muscle glycogen and an increase in liver glycogen in starved adult rabbits which were given rather large doses of adrenaline. More recently Cori has provided a more convincing demonstration of this phenomenon, and it appears likely that this is one of the usual physiological rôles of adrenaline. Whether a fall or a rise in liver glycogen is noted, depends on the time of sampling after the adrenaline injection (Luck and Sahyun). A fall is first observed, but the position is later reversed when lactic acid from muscle is built up into glycogen in the liver. Dextrose formed from the lactic acid may be responsible in part for the observed hyperglycæmia. It is only in the animal with intact pancreas that lactate from muscle has been shown to be formed into liver glycogen. This process, which may or may not proceed via dextrose, may be found to take place slowly in the apparent absence of insulin. It is interesting in this connexion to note that after adrenalectomy the recovery of liver glycogen in decapitated cats is accelerated (Evans, Tsai, and Young).

In discussing the hyperglycæmia produced by adrenaline one must consider breakdown of liver glycogen, the supply of lactate from muscle, and the still very debatable question of inhibition of carbohydrate oxidation. If adrenaline were secreted at an increased rate for a short time, one might expect first a decrease in liver glycogen and a hyperglycæmia, a fall in muscle glycogen, and an increase in blood lactate. Some of the lactate may be converted into dextrose, and insulin already available or liberated in response to the hyperglycæmia will facilitate the formation of liver glycogen. Under these circumstances there is presumably no excess of insulin.

INFLUENCE OF OTHER HORMONES

Thyroid.—In 1913 Kramer and Krause, 1924 Kusiyama, and in the same year Burn and Marks showed that liver glycogen could be reduced by repeated administration of thyroid extract. This effect on liver glycogen may be due to an increased activity of the thoracic autonomic nerve-fibres, with possibly liberation of "sympathin" in the liver, or may be in part due to the greater demand of apparently a variety of tissues for oxidisable material. There is, of course, evidence that the adrenals are made more active by thyroxine administration. The interesting work of Burn and Marks on the change in the response of animals to insulin and adrenaline as thyroid feeding is continued, and the correlation of these effects with the state of the liver glycogen, have been reviewed frequently. Interest in the effects of thyroxine on liver glycogen has been increased by the results of the recent work on the thyroid-stimulating hormone of the anterior pituitary. Eitel and Loeser[10] reported that injection of anterior pituitary extracts caused lowering of liver glycogen in normal but not in thyroidectomised guinea-pigs. The time relationships of the action of these extracts in the normal animals was similar to that which holds for thyroxine. It would, however, be unwise to conclude at the present time that the anterior pituitary may affect liver glycogen only through its thyrotropic hormone. As we will see later the diabetogenic fraction may exert an effect directly on the liver.

Pituitary extract.—It is perhaps unnecessary at the present time to consider the rôle of pituitary extract (vasopressin or oxytocin ?), since the balance of conflicting evidence suggests that this substance acts through liberation of adrenaline.

Adrenal cortex.—Numerous reports have been published recently on the rôle of the adrenal cortical hormone in carbohydrate metabolism. After double adrenalectomy in cats the carbohydrate reserves of the liver and muscles are depleted and there may be definite hypoglycæmia (Britton and Silvette).[11] This situation is corrected by providing the cortical hormone and glucose, but the effect is apparently not secured when glucose alone is given. This derangement of carbohydrate metabolism is not observed in some other species after suprarenalectomy, but Britton's recent work has added very necessary support to his contention that, in certain species, a disturbance of carbohydrate metabolism is one of the fundamental effects of cortical deficiency. Hypoglycæmia is, of course, observed in some cases of Addison's disease. It is certain that the next few years will bring us a great deal of new information concerning the effects of the hormone of the adrenal cortex on carbohydrate metabolism. There are many interesting experiments to be performed in adrenalectomised animals maintained by the cortical extract.

The Anterior Pituitary and Carbohydrate Metabolism in the Liver

In view of the signal importance of the work on the relationship of the anterior pituitary gland to carbohydrate metabolism which has been accumulating during the past seven or eight years, a short review will be given here.

The abnormalities in carbohydrate metabolism associated with acromegaly of long standing or with various pituitary tumours need not be discussed. The interesting new physiological work on carbohydrate metabolism might be dated from any one of many starting points. In 1908 Borchardt found that the extract of the posterior lobe of the pituitary raises blood-sugar. In 1911 Cushing observed that pituitary deficiency was accompanied by an increased carbohydrate tolerance. After insulin became available Burn demonstrated an antagonism between "pituitrin" and insulin, and several groups of workers showed that animals were more sensitive to insulin after removal of the pituitary body (Olmsted; Geiling). Attention was focused on the posterior pituitary. The interesting work on the relationship of the pituitary to carbohydrate metabolism conducted in Houssay's department during the last eight years began with the idea that the secretion from the posterior lobe counteracted some of the effects of insulin. Houssay and Magenta[12] presented very convincing evidence, in confirmation of the work quoted above, that hypophysectomised dogs are much more susceptible to insulin than normal animals. Houssay and Potick[13] removed the anterior lobes of the pituitary from toads with the production of hypoglycæmia and increased susceptibility to insulin, and subsequently Houssay and Biasotti[14] found no marked diabetes after complete pancreatectomy in these hypophysectomised animals. A graft of the glandular (anterior lobe) protects them against insulin, while a transplanted posterior lobe does not have this effect. Biasotti and Houssay report that hypophysectomised dogs may exhibit severe hypoglycæmia spontaneously, that they always do after a prolonged fast or injections of phloridzin, and that in some cases very low blood-sugar may be observed even after complete removal of the pancreas. This very striking finding that diabetes is absent or very mild in completely depancreatised dogs from which the pituitary gland has been removed has been confirmed by Regan and Barnes, by Soskin (personal communication), and D'Armour and Keller.[15] The longest survival period reported is six months, but many of these animals may have lived much longer by this time. Sugar and acetone bodies excretion (Rietti) in depancreatised or phloridzinised dogs which have lost their pituitary glands is much less than in otherwise comparable animals with the pituitary intact. Biasotti and Houssay seem to provide good evidence for the suggestion that it is a function of the anterior pituitary to regulate sugar formation from protein and possibly from fat or, in other words, that gluconeogenesis is greatly decreased in the absence of the anterior pituitary. In partially hypophysectomised animals the basal metabolic rate is low (Daggs and Eaton), but according to these workers and to Houssay there is no perceptible change in specific dynamic action of protein. The blood-sugar may be approximately normal and the usual type of carbohydrate tolerance curve may in some animals give normal figures.

Corkill, Marks, and White[8] using rabbits as test animals have recently confirmed many of Houssay's findings in toads and dogs and have extended them in some directions. Hypophysectomised rabbits are very susceptible to insulin and the hypoglycæmia is not easily relieved by adrenaline or vasopressin. Adrenaline is usually less effective in raising blood-sugar in these preparations and the suggestion is made that the glycogen reserves are not readily mobilisable after removal of the pituitary.

ANTERIOR LOBE EXTRACTS

The effects of extracts of the anterior pituitary may now be considered.

In 1926 Johns, O'Mulvenny, Potts and Laughton reported the production of hyperglycæmia in normal dogs which received "protein free" extracts of this gland. Houssay and Pottick found definite diabetogenic effects in toads. Evans, Meyer, Simpson, and Reichert produced diabetes of moderate severity in some, but not all, of their dogs which received daily injections of an alkaline aqueous extract prepared from beef anterior pituitary glands. This work was confirmed and extended by Houssay, Biasotti, and Rietti[16] who, using an alkaline extract of the anterior lobes, were able to produce hyperglycæmia, glycosuria, and acetonuria in normal dogs and rats, in partially depancreatised dogs, and in hypophysectomised, depancreatised dogs. Evans, in 1933, using normal dog, found lipæmia and hyperglycæmia. It is important to note that although pancreatic diabetes is somewhat modified by thyroidectomy in many species, the course of the condition in dogs after this operation is rapid (Yriart). It appears very unlikely on this ground that the anterior pituitary exerts its effect on gluconeogenesis through its thyrotropic principle. Furthermore, Houssay and Biasotti[17] have recently reported that hypophysectomy inhibits pancreatic diabetes in toads after removal of the suprarenals or thyroid. Transplantation of the glandular lobe exerts its diabetogenic effect in the absence of the adrenals or thyroid. While in these experiments both adrenals and thyroid were not removed in the same animal there seems little doubt that the diabetogenic effect was exerted directly on the liver. Campos, Curutchet, and Lanari[18] could not demonstrate the diabetogenic action of anterior lobe extracts in dehepatised toads.

While it is well established that removal of the adrenal medulla or interruption of thoracic autonomic nerve impulses increases the susceptibility of the animal to insulin, the evidence at present suggests that the substance in the anterior pituitary which affects the adrenal causes hypertrophy or prevents the atrophy of only the cortical tissue (Smith).

Anterior Pituitary and Fat Metabolism in the Liver

In 1930 Burn and Ling found that alkaline extracts of the anterior pituitary increased the acetone body excretion in rats, and in 1931 Anselmino and Hoffmann reported an increase in the acetone bodies of rats' blood after the injection of an extract of the anterior pituitary. These workers suggest that a rise in acetone bodies may be produced with these extracts without causing a hyperglycæmia. This work of Anselmino and Hoffmann has been confirmed in large part by Magistris[19] and the rise in acetone bodies has been noted in my laboratory by Mr. J. Campbell. Magistris has studied the increase in the acetone body content of rabbits' blood, using a modification of Engfeld's method. He believes that the active substance which caused an increase in acetone bodies is not identical with the sex hormone or hormones, with the growth-promoting substance, or the thyrotropic factor. Some of these points require confirmation. We have not as yet been able to obtain any evidence from the literature whether or not it is possible to separate this substance from the diabetogenic material described by Houssay and his collaborators.

It will be readily appreciated that these facts which I have outlined very briefly may necessitate considerable change in our conception of carbohydrate metabolism. It will be appreciated that some of the cases of diabetes which are observed at autopsy—and reliable investigators have stated that these may represent more than one-quarter of the total—have no obvious pancreatic lesion. While it is possible that serial sections of these glands might reveal some abnormalities *it is in the minds of many students* of the subject that diabetes may be caused in these cases, by over-activity of the anterior pituitary. It is perhaps easy to imagine a case of diabetes dying in coma as a result of a sudden increase in the rate of production of acetone bodies from fat in the liver without the production of a pancreatic lesion, but if the diabetes were long-continued, the results of Allen, Copp and Barclay, and Bowie, would lead us to expect that the hyperglycæmia would produce definite changes in the islands of Langerhans. On the other hand, the absence of widespread hydropic degeneration the islet cells in many cases of diabetes in which rglycæmia had been present for prolonged periods gests that in the human organism these cells may resistant to the stimulating effect of high blood-ugar.

These findings appear to give support to those of us who believe that "over-production" of dextrose is the major disturbance in the diabetic condition. It appears quite likely that the utilisation of dextrose by the exercising diabetic dog in the absence of insulin may be abnormal (Yater, Markowitz, and Cahoon)[20] and there may be complicating factors in the human diabetic but I can, as yet, find no escape from the conclusion that the resting depancreatised animal is able to utilise large amounts of sugar. The only hope for those who support the unadulterated "under-utilisation hypothesis" is to find a substance in the anterior pituitary which directly or indirectly inhibits oxidation of carbohydrate. The report of Campos, Curutchet, and Lanari, that the fall in blood-sugar produced by removal of the liver in toads is checked by implantation of the anterior lobe, is worth investigating in this connexion. In the normal state we may consider that the gluconeogenetic process in the liver is accelerated by the anterior pituitary (also thyroid and adrenals) and inhibited by insulin. In the absence of both of these hormones gluconeogenesis is usually sufficient to maintain a normal blood-sugar, but the process does not proceed at an excessive rate. If the thyroid or adrenals or both were also removed from the depancreatised hypophysectomised animal the liver might fail to produce sufficient sugar and fatal hypoglycæmia might occur much as it does in dehepatised preparations.

This field should not perhaps be left without brief mention of some reports of Anselmino and Hoffmann, who state that they have obtained a substance from the anterior pituitary which causes hypertrophy of the islands of Langerhans and the appearance of new islet cells. It would be unwise to make any comment on these results which are not supported by very convincing chemical data until further reports have appeared.

The Liberation of Insulin

Since insulin is one of the most important factors affecting the metabolism of carbohydrate in the liver, the control of insulin liberation is a pertinent question. I do not believe, however, that it is worth while to discuss again in detail at this time the chemical and nervous control of insulin secretion. The evidence seems overwhelming that a rise in sugar content of the blood increases the rate of output of insulin. There are many results which provide circumstantial and several supplying direct evidence for this view. The point which has been debated is whether the sugar acts directly on the pancreatic cells or through an effect on the parasympathetic centres in the hypothalmic region of the brain. The only objection which has been raised to the experiments of Gayet and Guillaumie [21] who added dextrose to the arterial blood supplying a pancreas grafted into the neck of a dog, was that the solution was hypertonic and that the tonicity rather than the sugar content caused the liberation of insulin and the hypoglycæmia. Recently Kosaka has injected 5 per cent. dextrose in saline into the pancreatic artery in chloralosed cats. The accelerated fall in blood-sugar under these conditions as compared to that which follows sugar injections into the portal vein or femoral artery, presumably indicates an increased rate of liberation of insulin. This result does not mean that the rate of insulin liberation is not increased by impulses along the parasympathetic system or that a *not yet* accurately located centre in the brain may not be stimulated to send impulses down the parasympathetic by increasing the concentration of sugar in the blood which bathes it. La Barre's work, of course, provides considerable evidence that this is the case, but Gayet and Guillaumie, who are also familiar with the somewhat exacting technique of cross circulation experiments, have not as yet been able to confirm these results. La Barre's interpretation of his findings may be correct and it has been rather widely accepted, but in view of Gayet's findings judgment must be reserved. There are many experiments which indicate that the vagus is not essential for the secretion of insulin. Other reviewers have recently covered this field.

A subject which holds considerable interest and which may be considered in conjunction with the liberation of insulin is the insulin content of the pancreas.

An investigation of the factors which influence the insulin content of the pancreas (age, diet, infection, &c.) has been slowly but steadily progressing in my department during the past few years. A method which apparently gives maximal yields has been used and considerable information on the insulin content of dogs' pancreas has been obtained. Severe infections may lower the insulin extractable by this procedure (Waters and Murray). We are not entitled to conclude that the rate of insulin liberation is also decreased, but this may well be the case. Our interest in the effects of duct ligation on the insulin content of pancreas was renewed by the reports of Mansfeld [22] that a ligation of the body of the pancreas in dogs which was followed by degeneration of the tail of the gland resulted in an increase in carbohydrate tolerance. Mansfeld believed that the increased tolerance persisted for several years, and that this depended upon the presence in the body of the degenerated tail of the pancreas. Mansfeld's results have been challenged on several grounds: (1) Nather, Priesel, and Wagner find that the increase in tolerance is only temporary; and (2) de Takats and Cuthbert [23] do not believe that the presence of the degenerated tail is responsible. They did not note any decrease in tolerance after removal of the degenerated part and therefore attribute the enhanced tolerance, which they also observe, to a greater activity or an increase in the number of islets in the part of the pancreas where the duct system is intact.

This is quite a different situation to that produced by ligation of the pancreatic ducts, which in the dog is followed by an extensive invasion of the whole gland by fibrous tissue. Generalisation on the effects of duct ligation on islet tissue is not permissible since the findings in different species vary, but the islets survive much better than the acini. In dogs, however, many of the islets eventually share the fate of the acini, and four or five months after duct ligation the number may be obviously less than in the normal gland.

In 1905 Diamare reported that oil injections into the pancreatic ducts of dogs eventually produce disappearance of both islets and acini. Allen and Jorns found similar results after ligation of the ducts. It is well established that some of the islet cells hypertrophy in the first few months after duct ligation, but I find no evidence in the literature that the number in dogs increases at any stage. It is probable that the hypertrophy of those remaining is related to the decrease in number. Wogelmuth has stated that the carbohydrate tolerance in these animals eventually reaches a low level, but, on the other hand, there are numerous but less convincing reports of normal dextrose tolerance curves. In the experience of Waters and myself these dogs may become mildly diabetic three or four months after duct ligation.

The most important point is the effect of duct ligation on the rate and extent of the liberation of insulin, and the evidence suggests that these may be decreased. Our own experiments forced us drastically to revise our previous conception that the insulin content of blood could be studied by the methods at present available. However, a method was developed (Best, Jephcott, and Scott) which appears to give optimal yields and which permits the recovery of added crude insulin from pancreatic tissue. Jephcott and Waters in my laboratory have noted that highly purified insulin is not recoverable by this process. The yield may be as large as 5000 units per kg. of dogs' pancreas, and while the product is not easily purified it may be satisfactorily assayed in a relatively crude form. Waters and I find that the insulin concentration remains at a surprisingly high level after duct ligation. The total amount of insulin in the gland diminishes greatly, however, and pancreas from duct-tied dogs is probably not a good source of insulin for the animal. There is certainly no evidence that the insulin content of the pancreas increases under these conditions. It is, of course, not justifiable to conclude from these results that the amount of insulin liberated, or that the rate of liberation, decreases after ligation of the duct. However, when these findings are considered in conjunction with the results of exacting carbohydrate tolerance tests, the eventual onset of diabetes, and the eventual degeneration of the islets, it appears highly unlikely that ligation of the duct of a part of the pancreas will favour insulin liberation from the affected part. It may be possible to obtain direct evidence whether or not the insulin content of the unaffected part of the pancreas is changed by interference with the duct system of the remainder. The increase in tolerance claimed by Mansfeld and by de Takats is not great. de Takats and his colleagues have been commendably cautious in applying the results of their interesting experiments on animals to clinical diabetes, and their experiences will probably not encourage others to try operative procedures.

MULTIGLANDULAR DISEASE *

BY OTTO LEYTON, M.D. Camb., D.Sc., F.R.C.P. Lond.
PHYSICIAN TO THE LONDON HOSPITAL

MUCH as I dislike adding another word to the medical vocabulary, I must do so now, because the hybrid word "polyglandular" can have no place in a lecture to the memory of so sound a classical scholar as the late Dr. Schorstein.

Multiglandular disease means many glands diseased and therefore is not a synonym for pluriglandular disease, which should mean more glands diseased. However, the actual meaning of a name in medicine is not of immense importance, because there is a convention in the way names are used. It is doubtful whether any complaint should be termed uniglandular: Graves's disease, which appears to be primarily a disease of the thyroid gland, frequently has associated with it enlargement of the thymus gland and probably also over-activity of the suprarenal glands. The proof of this overactivity seems to lie in the temporary improvement which follows severance of the nerves. At present the term multiglandular disease is reserved for those conditions in which several internal secreting glands are involved, whilst it is not possible to assert with confidence which gland is affected primarily.

The difficulty in determining which cells are responsible for a disease can be more readily understood when it is realised that a gland may make an excess of its normal product without any increase in its size. Most physicians with experience have seen cases of Graves's disease with great emaciation, tachycardia, protuberant eyes, fine tremors, sweating, and glycosuria without any recognisable enlargement of the cervical lobes of the thyroid gland, and in which X ray examination of the thorax has proved that neither a substernal nor intrathoracic lobe is responsible for the condition. It is true that in these cases histological examination leaves no doubt that there is an excessive activity of cells, but this does not apply to some other conditions which appear to be due to excessive production of an internal secretion.

---

* An abstract of the Schorstein lecture delivered at the London Hospital in October, 1933.

Observations upon spontaneous hypoglycæmia provide a good instance. In this rare disease, in which the concentration of sugar in the blood falls so low as to cause symptoms (symptoms which may be so insignificant as a sensation of apprehension or so serious as homicidal *mania*), adenomata consisting of beta cells of the islands of Langerhans have been found and the removal of the adenoma has led to recovery. This finding, however, is far from invariable; in some cases simple hypertrophy of the islands of Langerhans has been demonstrated, whilst in others the most careful examination has failed to discover any tumour or hypertrophy, and removal of a part of the pancreas has not benefited the patient.

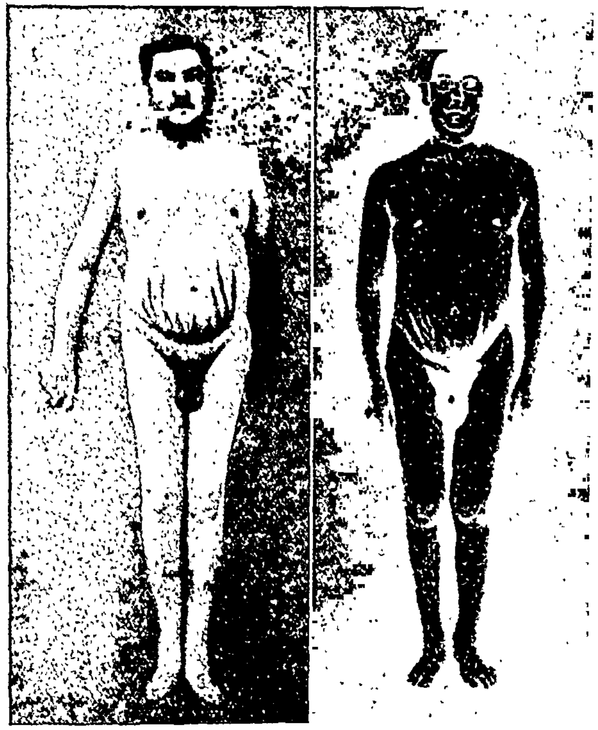

FIG. 1.—On the left: Raab and Krause's case. On the right: Leyton, Turnbull, and Bratton's case.

It might be argued that in all cases of spontaneous hypoglycæmia an excess of beta cells of the islands of Langerhans would be found if the search were complete, but this can be refuted by the evidence we possess.

The pancreas of the normal individual has the capacity of making sufficient insulin to cause death from hypoglycæmia. This has been shown repeatedly when experiments have been conducted with the object of determining the maximum rate at which the healthy individual is able to store sugar when dextrose is injected into a vein. A short time after ceasing the injection profound hypoglycæmia may develop, requiring the administration of sugar over a considerable period; occasionally hypoglycæmic coma has necessitated the injection of carbohydrate into the rectum. Further evidence exists in those patients suffering from diabetes mellitus, who after having been on fixed diets and doses of insulin for months or even years, suddenly develop intense hypoglycæmia causing coma from which they would never emerge if they were not supplied with liberal quantities of sugar. It may be necessary to continue to give carbohydrate in large amounts at short intervals for days or even weeks after the administration of insulin has been stopped. This seems to show that cells which have been underactive for long periods may awaken to dangerous overactivity. It is therefore established beyond doubt that hyperinsulism does not necessitate the presence of an excessive number of the beta cells of the islands of Langerhans.

It may help us to understand multiglandular disease if we accept the principle that a gland producing an excess of its normal secretion or even an abnormal secretion need not necessarily show any morbid change recognisable by present-day methods.

MULTIGLANDULAR DISEASE AND PITUITARY BASOPHILISM

The functions of the pituitary gland are so numerous that as its mystery was gradually unfolded it appeared that the explanation of multiglandular disease would be elicited and the name replaced by "basophilism." Indeed at one time Harvey Cushing[1 2] tended towards that view, because he had collected many cases of the syndrome which had been associated with an excess of basophil cells in the anterior part of the pituitary gland. This view he has modified since cases have been recorded with similar syndrome but lesions in tissues other than the pituitary gland. I yield to no man a greater admiration for the work of Prof. Cushing, and later shall refer to some of the benefits his investigations have bestowed upon patients suffering from multiglandular diseases. It is in no antagonistic spirit that to-day I refer to cases of multiglandular disease due to lesions outside the pituitary and compare them with cases in which either basophil adenoma of the pituitary has been demonstrated, or which have signs which place the diagnosis almost beyond doubt.

I

The first pair (Fig. 1) consists of two men, one described by Raab[3] with autopsy by Krause,[4] and the other a case which was in one of my wards with an autopsy by Turnbull and Bratton.[5]

They both developed their diseases in their thirty-second year; both showed septic foci shortly before the end; both were of more than the average height and the legs of both were long compared with the trunks. The external *genitalia* were normal but both became impotent. The faces and abdomens were obese and the legs slender. Broad purple lineæ atrophicæ radiated from the pubes over the abdomens, probably due to their rapid gain in weight. The main differences which might have been noted during life were that Raab's patient had backache probably caused by kyphosis resulting from osteoporosis. There was no evidence of osteoporosis in my case. In Raab's case the sella showed that the space was becoming larger; in the London Hospital patient the sella appeared to be normal, but he developed hyperglycæmic glycosuria whilst under observation. At the end of November, 1927, his sugar tolerance appeared to be normal, but by the following January the sugar content of his blood after a fast was 0·20 per cent. The blood contained 5,100,000 red cells and 88 per cent. hæmoglobin, proving an absence of polycythæmia which is not an uncommon feature of pituitary basophil adenoma; on the other hand, his blood pressure was 170 mm. Hg. Hypertension is found in the majority of cases of basophilism.

The lesions found at the autopsies were strikingly different. The only common finding was enlargement of the thyroid gland. Krause found an adenoma of the pituitary gland consisting chiefly of basophil cells; there was definite *osteoporosis*; the suprarenal glands had undergone autolysis. In the London Hospital case Turnbull and Bratton found a tumour of the thymus gland which upon histological examination was shown to consist of oat cells and secondary growths in the lungs. The suprarenal glands were greatly enlarged, the cortex more than the medulla. Serial sections of the pituitary gland stained with special methods failed to show any excess of basophil cells.

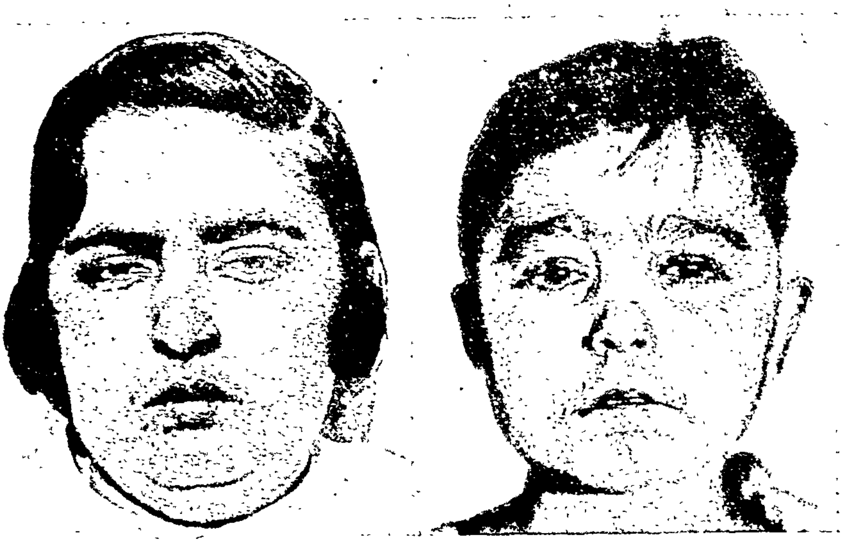

FIG. 2.—On the left: Cushing's suspected case of basophilism. On the right: Case of primary cancer of thymus.

II

The second pair of patients were a girl who was comparatively recently under the care of Prof. Cushing and a boy who was in one of my wards in the latter part of 1927.

The most striking similarities in these cases are the excessive growth of hair upon the face and the protuberance of the abdomen. Both faces became rather bloated through abnormal deposition of fat (Fig. 2). The photographs show excessive hair in both cases—an excess on the upper lip, the chin, and at the sides of the forehead. I shall quote Prof. Cushing's words in the description of the girl.

> "There was precocious adolescence, at 10 years of age, associated with normal menses which continued for three years and then abruptly ceased. . . . She acquired a peculiar plethoric appearance with an abnormal growth of hair on the brows, lip, and chin. . . . She became increasingly abdominous with progressive increase of the purplish striæ atrophicæ" (Fig. 3).
>
> "She had persistent backache and became round shouldered with the loss of 4 cm. in measured stature due undoubtedly to the roentgenologically evident decalcification of the vertebræ and abnormally high calcium elimination. . . . A spontaneous fracture of the pelvic bone, evidently in a tumour, has healed with callus formation. . . . She had a subnormal basal metabolic rate, a lowered tolerance for carbohydrates, and a high blood pressure, presumably indicating secondary involvement or imbalance of other glands—parathyroid, thyroid, pancreatic islets, and adrenal—to almost any of which the syndrome might have been ascribed. . . . Her urine tested by two observers on both rabbits and immature mice proved to contain follicular-stimulating substance indistinguishable in its effect from prolan."

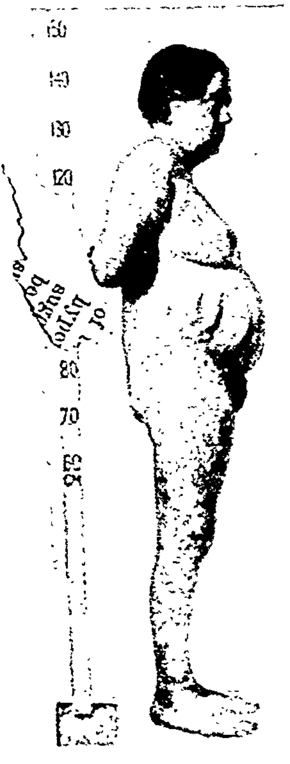

FIG. 3.—Cushing's case (October, 1932) showing abdominal protuberance.

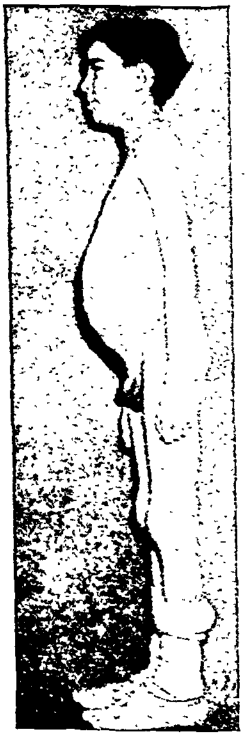

FIG. 4.—Case of cancer of thymus, showing abdominal protrusion.

This patient did not die and therefore the morbid conditions associated with the syndrome have not been placed beyond doubt, but the probable cause may be deduced from the subsequent history which I postpone relating until I have described the parallel case.

The boy, aged 11, had had his appendix removed quite recently in a surgical ward of the London Hospital by Mr. E. C. Lindsay and had made an uninterrupted recovery. Whilst he was at the convalescent home, sugar was found in his urine and his abdomen became protuberant. His facial expression altered so greatly in three weeks that he was not recognised by the sister of the ward in which he had been for the operation. His face was fat and the skin over his cheeks was stretched. He had developed a moustache, with some hair on his chin which formed a meagre imperial, his eyebrows were thick and plentiful, and there was an excess of hair on the sides of his forehead. His legs were long when compared with his trunk, the abdomen protuberant, and the limbs thin (Fig. 4). The genitalia were normal for the age, there was no hair in the axillæ nor on the pubis. He did not develop polycythæmia, nor was his blood pressure above the average normal—conditions comparatively common in basophilism.

Hyperglycæmic glycosuria appeared quite early in this case. Skiagrams of the skull did not show any abnormality of the sella turcica nor any areas of decalcification of the calvarium. It was thought that the diagnosis lay between disease of the pituitary gland and hypertrophy of the suprarenal cortex. Since the patient had hyperglycæmia and skiagrams did not show any displacement of the kidneys I decided that an exploratory operation was not justifiable. The treatment consisted in controlling hyperglycæmia by diet and insulin. When fully controlled he was allowed to leave hospital, but he returned fourteen days later because he had developed severe headache and polyuria. Early in the morning of the day he was admitted he had had a fit. One of the subsequent fits was described by my house physician, Dr. O. Thomas, in the following words :—

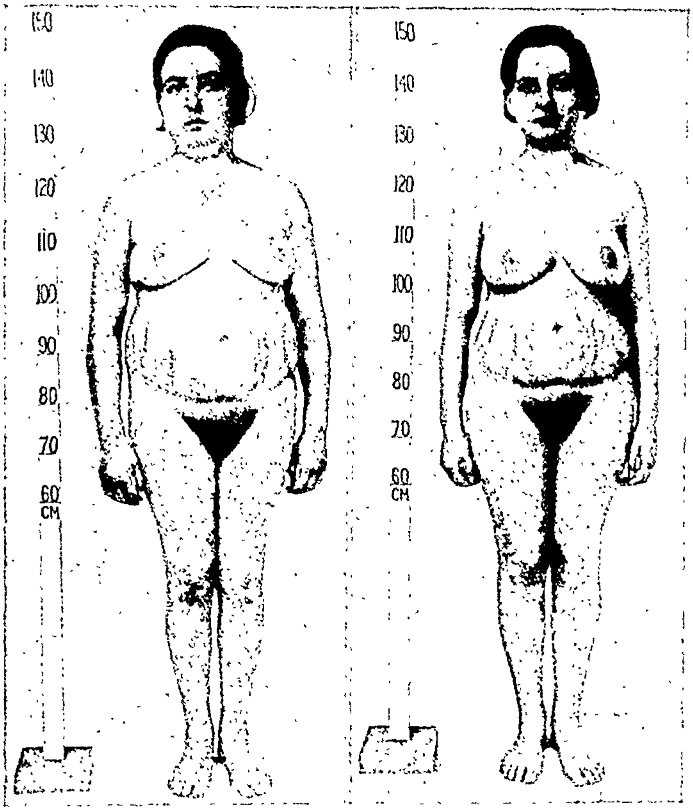

FIG. 5.—Cushing's case. On left: Condition on August 12th, 1932. On right: Condition on March 11th, 1933, after irradiation of pituitary gland.

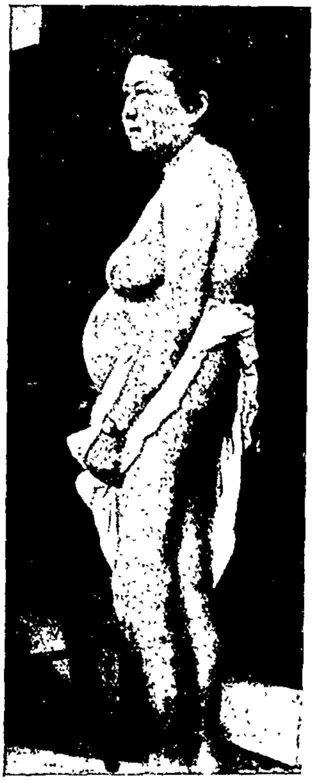

FIG. 6.—Turney's case.

> *Fits started* by slow tonic movements of the left arm and a slow flexion of the left elbow followed by extension. Then the right arm held very rigidly in flexion was drawn up in the front of the chest. The eyes followed by the whole head turned slowly to the left. The left side of the face drawn up. The whole body passed into tonic contraction for about 15 seconds. The pupils were dilated and fixed. The patient became cyanosed. Clonic spasm of all four limbs followed for about one minute, the arms being held in flexion, the right leg was flexed, and the left extended. The position of the legs differed somewhat in different fits.
>
> The pulse was rapid, 120 during the fits. On cessation of the spasm the patient lay quietly and breathed stertorously. The plantar reflex was extensor on the right side and normal on the left side. The urine contained sugar and a trace of albumin. The sugar content of the blood during a fit was 0·25 per cent. and the urea content 0·051 per cent.

These observations make it unlikely that the fits were due to either hypoglycæmia or uræmia, unless one takes the view that so-called hypoglycæmic fits are not due to the lack of sugar in the blood but to a toxic decomposition product of glucose which is usually dependent upon the sugar in the blood falling extremely low. Examination of the cerebro-spinal fluid failed to show any abnormal content.

As already stated, the similarity in these two cases was the excess of hair upon the face, the increase in the size of the abdomen, and the diminished tolerance for carbohydrates. That the girl suffered from basophil adenoma of the pituitary gland seems probable because she improved immensely after irradiation of the pituitary (Fig. 5), and because the gonadotropic substance present in the urine disappeared under such treatment. The autopsy of the boy was performed by Dr. Bratton and the tissues were examined by Prof. Turnbull. The pituitary gland was examined in serial sections with a special staining which proved that it did not contain an excess of basophil cells. On the other hand, as in the case described above, an oat-celled cancer was found in the thymus, with secondary growths in the lungs. In this boy, too, the thyroid was hyperplastic and the suprarenal glands hypertrophied, the size of the capsules being relatively greater than that of the medullæ. The cause of death was not demonstrable at the autopsy, and it was suggested therefore that it might have been due to hypoglycæmia. Arguments against that view have been stated above.

III

A third pair which may be compared consist of the case described by Turney [6] in 1913 and one under the care of Kepler [7] at the Mayo Clinic comparatively recently. Turney described his case very graphically, and all interested in the syndrome should read his description.

> The patient, an unmarried woman aged 25, enjoyed good health until suddenly menstruation ceased and

she began to put on weight rapidly. She had noticed that for two years her legs bruised with undue readiness. Her great trouble was pain in the back due apparently to a kyphotic curve in the upper thoracic region. Although she had a subnormal temperature she preferred cold weather to hot. Her mental condition was normal. Her height diminished from 5 ft. 2 in. to 4 ft. 11½ in., the result no doubt of increasing kyphosis.

The face was florid and fat, the hair dry and scanty. The expression was bright and the manner alert. The skin was dry but not harsh. Axillary and pubic hair was scanty, but there was an excess of hair all over the back. The mammæ were pendulous and the abdomen had the contour of a full-time pregnancy (Fig. 6). Numerous broad lineæ atrophicæ were visible over the abdomen and thorax. The legs were very thin, especially the thighs. Skiagrams of the skull suggested enlargement of the sella turcica. The blood pressure was 200 mm. Hg. Examination of the eyes suggested that there had been small retinal hæmorrhages. The red cells rose at one time to over 8,000,000 per c.mm.

The patient later came under the care of Dr. Parkes Weber [8] and he reported that she had several spontaneous fractures. Abscesses led to death seven years after the beginning of the disease. The autopsy revealed chronic nephritis, fatty infiltration of the liver, and an enlarged left suprarenal gland with a bulky cortex. Nothing abnormal was noted in the pituitary or thyroid glands.

The autopsy was in 1914, long before the small basophil adenomata had been described, but it seems probable that this case was one of basophilism. Kepler's case, on the other hand, although in many respects the signs were similar, proved to be one of cancer of the thymus.

Her last illness began in January, 1932, when she was 46 years old. Before that she had had two operations upon the thyroid, appendicectomy, and drainage followed by removal of the gall-bladder. She stated that she had always had a slight growth of hair on her face, but that it had been insignificant until January, 1932, when it grew rapidly and made shaving daily necessary. At the same time her face became fat and florid. In June, 1932, she developed intense hyperglycæmic glycosuria and hyperthyroidism. Her menstrual periods had ceased at the beginning of the illness. Her legs became thin and weak. The blood pressure averaged 170 mm. Hg systolic and 80 diastolic. A small hæmorrhage occurred in the left retina. The sella turcica was normal upon roentgenographic examination. There were metabolic disturbances leading to alkalosis and also to a fall in the chloride ions in the blood with a fall in the calcium content. The skull was irradiated with apparent temporary improvement.

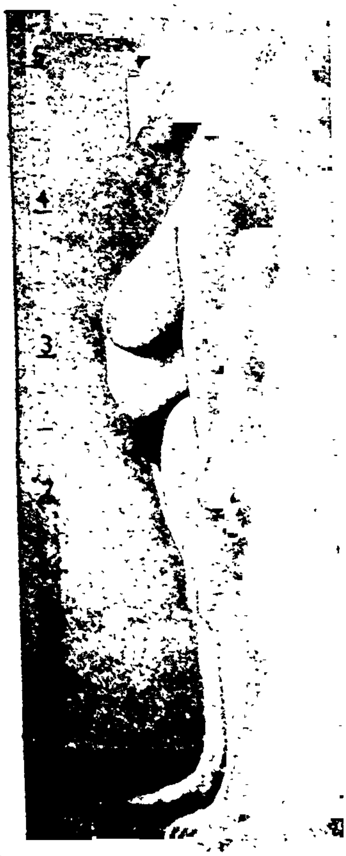

FIG. 7.—Case in the London Hospital.

At the end of June, 1932, she died. Autopsy disclosed a normal pituitary gland both grossly and on microscopic examination of serial sections with special stain. A thymic tumour about 5 cm. in diameter was present. Both suprarenal glands were hyperplastic with a combined weight of 49 g. There was a small abscess in the pancreas. The thyroid showed multiple degenerating colloid and fœtal adenomata in a colloid thyroid with intra-adenomatous parenchymatous hypertrophy.

IV

A fourth pair for comparison are of less value because the diagnosis in one of the cases has not been established by the morbid pathologist. One of the cases was recorded by Dr. Hurst Brown [9] some six years ago, and the other is still under my care. Dr. Hurst Brown described his case as follows.

A woman, aged 45, complained of thirst, disinclination for food, weakness and numbness of the legs, blurring of vision, and sinking sensation in the pit of the stomach. The onset of the disease was menorrhagia, for which she had hysterectomy. When admitted to hospital her face was florid and pigmented, the breasts and chest were also pigmented. Her weight was 12 st. 8 lb.; in other words, she was obese. The urine contained sugar and the reaction to insulin was irregular. X ray examination failed to show any alteration in the pituitary fossa. She became bald but grew hair on the chin and upper lip. She did not develop striæ atrophicæ.

The autopsy revealed a typical oat-celled cancer of about 1 cm. diameter in the lungs. There was hyperplasia of the thyroid gland. The suprarenal cortices were enlarged. The pituitary gland was enlarged and much colloid was found in the large vesicles in the intermediate lobe.

This case may have been one of basophilism with cancer of the lung; but it simulated closely the cases of primary cancer of the thymus and the microscopic appearance of the cells was very similar too.

The other case is a woman presenting many of the characteristics of basophilism. Fig. 7 shows the protuberance of the abdomen, the hypertrophy of the breasts, the absence of fat over the gluteal region, the slender legs, and moderate kyphosis. The patient has hyperglycæmic glycosuria controlled by insulin. She has had her pituitary region irradiated, but the hyperglycæmia has persisted although she reports that she is feeling better.

CONCLUSION

Four cases of multiglandular disease have been outlined which have apparently been due to new growths in tissues other than the pituitary gland; in three of these the primary growth was in the thymus, whilst in one a growth of similar cells was found in the lungs.

At least 14 cases of multiglandular disease associated with basophil adenoma of the pituitary gland have been recorded. The various internal secreting glands involved were—

	Basophilism.	Neoplasm elsewhere.
Thyroid	3	4
Suprarenal cortex	8	4
Parathyroids	2	—
Osteomalacia	5	1
Thymus	0	3

I fear that the data are quite insufficient to draw any conclusion as to the cause of multiglandular disease. Too often the theorist in his study suggests explanation of disease which is proved incorrect by the investigator in his laboratory. It is therefore with all due humility that I suggest further investigation of the suprarenal cortex with new stains which may perhaps show that it consists of cells of slightly different morphological character secreting different substances. Hyperplasia of the suprarenal glands often causes virilism or precocious development of the reproductive organs. In three cases there was great hypertrichosis without virilism. Overactivity of the suprarenal cortex seems to account for the symptoms most satisfactorily. Since Collip[10] has been able to isolate an adrenotropic substance from the pituitary gland it seems within the bounds of possibility that the excess of basophil cells produces an excess of this hormone. Whether other tissues can produce an adrenotropic substance or whether the neoplasms of the cases referred to above stimulate the basophil cells in the pituitary to excessive secretion without causing hyperplasia remains a problem which no doubt will be solved in the near future.

THE USE AND ACTION OF HISTAMINE IN RHEUMATISM

BY BARNETT SHANSON, M.R.C.S. Eng.
LATE RESIDENT MEDICAL OFFICER, HARROGATE ROYAL BATH HOSPITAL; AND

CYRIL G. EASTWOOD, B.Sc., M.B. Manch.
LECTURER IN PHYSIOLOGY AND HYGIENE IN THE UNIVERSITY OF LEEDS

IN recent years histamine has been used in the treatment of rheumatism and good results have been recorded, chiefly by continental workers. In 1931 Deutsch[1] demonstrated the use of this substance before the Berlin Medical Society and reports of its use have since been published by Kaufmann,[2] Bettmann,[3] Schenck,[4] and recently by Govaerts.[5] Each of these workers administered histamine by ionisation. Ravina,[6] reviewing the use of histamine, states that Jacchia[7] has given it by subcutaneous injection. Although the subject has received considerable attention, no full account of the use and action of this drug in rheumatism has yet appeared. There is also marked difference of opinion as to the type of case which is suitable for this treatment.[2,3,8]

METHOD AND RESULTS

We have studied the effects of histamine and thio-histamine * in the treatment of a series of 70 adult cases of chronic rheumatism and allied disorders. The series included examples of rheumatoid arthritis, fibrositis, osteo-arthritis, subacute rheumatism, and gout. It was not possible to withhold other treatment (physiotherapy) from these patients; nevertheless the results due to histamine could be easily recognised by the time relation which they bore to the injection.

Histamine was given by subcutaneous injection. The solution was prepared in the strength of 1 mg. of histamine acid phosphate to 1 c.cm. of saline and 0·5 per cent. phenol was added as a preservative. The initial dose was 0·1 mg. (i.e., 0·1 c.cm.), and this was increased daily by 0·05 mg. until definite improvement was observed. A satisfactory dose was usually found to lie between 0·1 and 0·5 mg. This dose was repeated two or three times a week and
further increased if the response diminished.

to avoid chill if a transient rise in temperature
as described below. Histamine in the doses me
did not affect menstruation. As an extra pr
adrenaline, the physiological antidote to histamine
hand. We may add, however, that we never had
to use it. Observations were made upon the bo
perature, pulse- and respiration-rates, blood press
surface temperature (by the thermo-couple and g
meter method).

The following account of the effects of hista
rheumatic patients applies equally to thio-hi
given in appropriate doses. The response to hi
varied from patient to patient, and even in t
patient at different times. The following is
all the effects which were observed : flushin
of pain, increased range of joint movement,
vasomotor symptoms, sweating, headache, di
drowsiness, increased appetite, a sense of wel
changes in blood pressure and temperatur
paræsthesiæ.

Flushing.—Although relief of symptoms is t
important of these phenomena therapeutically
ing appeared first, was the most constant a
often striking. It generally occurred within
minutes of injection, and lasted from fifteen t
minutes. With the smaller doses the flushi
confined to the face and neck. With the large
flushing was accompanied by erythema and a
of warmth over the whole body, but the
generally an interval between the facial flush
occurrence of general bodily warmth. Someti
flush had a patchy or mottled distribution o
face and neck. In a number of cases flushing r
later in the day, either without obvious ca
evoked by some stimulus such as a hot drink.

Relief of pain and increased movement.—Pa
relieved and movement of joints increased, oft
surprising degree. This occurred in a few m
Occasionally, a few hours, and more rarely a fe

---

* The British Drug Houses Ltd.

elapsed before improvement appeared. The response was frequently dramatic. For example, a patient unable to close his hand owing to limitation of finger flexion would close the fist completely within a few minutes of the injection. Again, a knee-joint would be fully extended after having been partially flexed for years. In some cases definite relaxation of muscular spasm occurred, and this was most strikingly demonstrated in the case of the sternomastoids. It is necessary to point out that dramatic increase in movement did not as a rule last longer than a few days. The benefit, however, did not entirely disappear, a small but definite improvement persisting, to be added to by the effect of subsequent injections.

Relief of vasomotor symptoms.—Vasomotor disturbances were common and consisted of sensations of coldness in the extremities or all over the body, and pale or cyanotic hands, with or without trophic changes. Histamine relieved these symptoms in almost every case. A sensation of body heat was frequent. This occurred soon after the flushing of the face and even when erythema was not visible. After a few hours it would subside, a lesser degree of warmth often persisting for several days. We have frequently seen both cyanotic and deathly pale hands rapidly take on a healthy pink colour and perspire freely, the patients declaring that they feel "alive" and warm again.

The remaining effects which may follow an injection of histamine, although less important therapeutically, are of considerable interest from the physiological point of view.

Headache and dizziness.—A slight degree of fullness in the head or headache with or without dizziness was not uncommon, and lasted from a few minutes up to half an hour. Occasionally it would begin with violent throbbing and persist as a dull ache for several hours. It was not directly proportional either to the size of the dose or to the amount of flushing: a marked flush was sometimes followed by no headache at all, and a slight flush by a marked headache. It was not usually sufficient to cause undue inconvenience, but when necessary was easily relieved by aspirin. The headache and dizziness, when they occurred, were generally felt within a few minutes, but in a number of cases there was a latent period of many hours. They could generally be mitigated if the patient lay down for half an hour after the injection.

Sweating.—Sweating occurred less commonly than the effects already described. It usually appeared within a few minutes of injection and frequently was localised to the palms of the hands. More rarely the onset of sweating was delayed for some hours, occurring perhaps during the night, sometimes profusely.

Drowsiness.—Patients often experienced a feeling of drowsiness within several hours. As a rule this was slight and of short duration. In a few cases the drowsiness led to a strangely deep sleep, from which the patient awoke after a few hours very refreshed.

Appetite and well-being.—A sense of well-being was frequently noted. When the injection preceded a meal there was occasionally a marked increase in appetite. These effects rarely lasted longer than one or two days.

Blood pressure.—With histamine a fall in blood pressure commonly occurred to the extent of 20–40 mm. Hg, but this never lasted longer than five minutes. In cases complicated by high blood pressure the fall was greater. With the smaller doses of thio-histamine the blood pressure was only rarely affected.

Temperature.—A rise in mouth temperature up to 1·5° F. was often recorded. In a few cases, however, the temperature fell. A typical chart shows that the maximum change occurs within half an hour and the temperature returns to normal fifteen to thirty minutes later. These findings were quite inconstant. We found that not infrequently the mouth temperature varied as much as 0·5° F. between successive readings taken at five-minute intervals, apart altogether from the administration of histamine. This led us to observe the temperature at intervals of a few minutes before as well as after the injection. Our remarks apply only to those observations which were thus controlled. The skin temperature of the cheek rose considerably and in one case approximated mouth temperature.

Pulse and respiration.—The pulse-rate was as a rule either unchanged or slightly increased. The respiration-rate was never affected.

Paræsthesia.—Some kind of paræsthesia was occasionally met with. This took the form of tingling or burning in various parts of the body. It was always transient and caused no discomfort.

Apart from the needle prick the injections were painless, and untoward symptoms never arose.

CASES ILLUSTRATING THE EFFECTS OF A SINGLE INJECTION

Woman aged 41; rheumatoid arthritis 18 months' duration. Walked with two sticks on account of flexion of the knees. Sixth injection, 10 A.M., 5 mg. thio-histamine intramuscularly. Within a few minutes, slight flushing of the face and warmth of body occurred. In twenty minutes the patient felt looser behind the knees, which showed increase in movement. Walking was markedly improved. No headache, but slight drowsiness all day. The following morning the improvement had largely disappeared. A small but definite benefit, however, persisted. In this case the mouth temperature rose 1° F. within fifteen minutes and returned to normal fifteen minutes later. No acceleration of pulse or respiration.

Man aged 59; fibrositis and arthritis of many years' standing. Swelling of small joints of fingers and pale clammy hands; unable to close fists completely; always feels cold and says "nothing ever warms me." Second injection, 11 A.M., 0·15 mg. histamine subcutaneously. Face flushed and body felt warm. The hands also became warm, the colour changing from white to pink, and he was able to close his fist completely for the first time in many months. These effects occurred within a few minutes of the injection and had not disappeared four days later, when the next injection was given. He also experienced general well-being and a temporary increase in appetite.

IONISATION

The administration of histamine by ionisation was first introduced by Deutsch in 1931,[1] and has recently been described in detail.[9] The positive pad is soaked in a 1 in 5000 solution of histamine. A treatment usually lasted twenty minutes, and at the end of this time the skin under the positive pad was red, hot, and usually blistered. We found that therapeutic effects were purely local and were apparently the result of local galvanism, heat, and counter-irritation. Pain and swelling were relieved in all types of cases. The most striking results were obtained in cases of chronic arthritis of knee and ankle joints which had recently flared up with increase of swelling. With regard to general effects, flushing of the face and headache often occurred but general therapeutic effects were absent.

We wish to express our thanks to the honorary physicians of the Harrogate Royal Bath Hospital for their interest and encouragement throughout this work. Also to Prof. B. A. McSwiney, of the University of Leeds, for helpful advice and criticism. One of us (C. G. E.) is in present tenure of the Worswick fellowship of the University of

Manchester. Some preliminary work was done in the clinical research department of that University, and thanks are due to the director, Dr. J. F. Wilkinson, for continued interest.

THE CLINICAL APPLICATION OF HISTAMINE IN RHEUMATISM

BY F. SEVERNE MACKENNA, M.B. Dub.
PHYSICIAN, ROYAL BRINE BATHS CLINIC, DROITWICH SPA

HAVING been one of the first to employ histamine as a routine treatment for various rheumatic conditions, it may be of interest to explain its clinical application. In a recent note by Bisset and Woodmansey[1] the theory and the results of various investigations were set forth, but there is perhaps need for a fuller description of the practical findings.

It is essential that a suitable type of case be selected for treatment, such being osteo-arthritis, rheumatoid arthritis (not in the acute stage), chronic villous arthritis, fibrositis, and neuritis. An opportunity of observing the reaction of the gouts has not occurred, but other writers[1] have reported good results. Similarly, its use has been proved in intermittent claudication,[2] and in muscular atrophy due to trauma and disuse.[3] It has no place in the treatment of infective arthritis or acute rheumatoid arthritis, or where there is marked failure of compensation in the heart.[4]

The course of the disease in most cases appears to be uninfluenced[5] by histamine, but there is no doubt that its use accelerates recovery from those conditions which can definitely be cured, such as fibrositis and neuritis. In a long series there have been extremely few failures, a result which can in the main be ascribed to two causes—namely, careful selection and personal application of the treatment. The method is one requiring such unremitting attention to every phase, on account of the daily variations in the reaction of the same patient, that it does not seem practicable to delegate the administration, in the form of a prescription, to a second person. But if these two requirements are satisfied, and if the use of histamine is combined with suitable bath treatment, the results unquestionably surpass those obtained with previous methods.

The histamine which has been used is that prepared by Hoffmann-La Roche in the form of tablets and electrolytic ointment. The tablets, which are used for making a stock solution of the required strength, were early discarded in favour of the ointment, which seemed to give better results and was much more convenient to use. At the present time it is employed in two ways: ionisation and massage.

IONISATION

The affected part is smeared with ointment without any preliminary cleansing. The use of benzene has been advocated by Spicker,[2] but after an extensive trial there seemed to be no advantage in removing the surface grease, and this has been discontinued. A lint pad, wrung out of saline, is placed in the usual way over the part and connected to the anode of the apparatus. A similar pad, connected to the cathode, is applied to the body either in an indifferent place or with the idea of getting a definite "through and through" effect, although the advantage of this has not been proved. The amount of current used vastly exceeds that advocated by other workers, who rarely go beyond 15 milliampères, whereas I always give each patient the maximum which can be tolerated, and this frequently amounts to 100 and 150 ma. The current is raised to the maximum as rapidly as may be compatible with comfort, and is maintained at the greatest height the patient will allow during the remainder of the sitting, being at the end of that time cut off without hesitation.

The amount of current which a patient will tolerate varies enormously from day to day, and unless the maximum current is given for each sitting the greatest benefit is not being received. The amount of current passed does not seem to bear any relationship to the size of the pads, except where a very small area is being treated, when there is naturally a concentration. The patient immediately announces a tingling and intense itching at the site of the anodal pad, and this may gradually increase, may remain stationary, or may rapidly lessen. It is frequently noticed that these symptoms pass off as the current is increased. There is an accompanying feeling of local warmth, and the patient must be told how to distinguish between this and the burning caused by the concentration of the current in one spot. He is told also to complain at once if the limb begins to throb, if the face flushes, or if there is pain in the head. The flushing of the face must, however, be looked for by the operator from the passing of the first milliampère, frequently becoming apparent a few moments before the patient realises its presence, and those few moments may mean the avoidance of a bad headache, as it is on the first suspicion of a flush that the current is cut off. This may take place after three minutes or not until 20 or 25 minutes have passed.

When the patient complains of throbbing or excessive heat the current is reduced the necessary amount to stop these phenomena. When the current is cut off a well-marked urticaria is found under the anodal pad, corresponding to it in size or irregular in shape; it may be discrete or may have coalesced to form a raised plateau. There is violent itching, which is allayed by dusting with talcum powder and usually passes off in a few minutes to half an hour. The rash itself often fades rapidly and has not been found to remain longer than 130 minutes. It is advisable where possible completely to surround the part with the anodal pad, and an arm or foot bath can be used as the positive electrode for treating an extremity which has been well smeared with the ointment or can be used to replace the cathodal pad.

With the treatment the patient experiences an immediate relief from pain, either complete or partial, and can demonstrate a greater range of movement where previously there was restriction. This lessening of pain is always present and may last a few hours, a few days, or permanently. In addition, there is a feeling of local warmth and general well-being. The undesirable results which must be carefully watched for include headache or a feeling of fullness in the head, tachycardia, a feeling of constriction in the chest with consequent breathlessness, burning, and faintness, any one of which is an indication for the immediate cessation of the sitting. Treatment may be given daily.

MASSAGE

The ointment has given excellent results when used as a basis for massage in fibrositis and chronic villous arthritis, but in these cases it is necessary to make allowance for the natural benefit resulting from the massage alone. There is, however, no doubt that the addition of histamine produces markedly superior results.[6] In a few minutes patches of urticaria appear, but they rarely exceed the size of a split pea and are not usually numerous. Symptoms of toxicity likewise are seldom seen. On the whole results are less satisfactory than when ionisation is used, but where massage is desired histamine can advantageously be employed, and it may safely be used in cases of failing compensation which cannot have ionisation. It has not been observed with Spicker[2] that "the greatest rash appears in the painful areas while those not affected hardly react." Neither the practice of scarifying the skin before inunction as advocated by Vas,[7] nor the method of injecting histamine peri- or intra-articularly by the technique of Vezér,[4] Faber,[8] and Jacchia[3] have been attempted, mainly because the results by other methods have been eminently satisfactory. A preliminary exposure to infra-red rays appears to be beneficial.

ILLUSTRATIVE CASES

CASE 1.—Fibrositis, mainly in back and knees. Duration 15 years. Patient had always received benefit from spa treatment, but returned each year in the same condition. In 1932 there was considerable improvement with various baths, douches, and massage, but on returning in 1933 was found to have relapsed. Again had baths, massage, and infra-red radiation, but was making no progress. Was given ionisation with histamine to the lumbar region for 10 minutes, current up to 45 ma., and at the conclusion of the application was found to be free from all pain in the back, and similarly at the next two sittings the knees were also painless. Treatment was repeated on five further occasions. Now, six months later, the patient reports that there is still freedom from pain and that she has not felt so fit for many years.

CASE 2.—Neuritis of traumatic origin, duration two months, caused by playing badminton. When seen there was slight loss of extension of the right elbow, with considerable neuritic pain, aggravated by attempts to extend the joint. Ionisation with histamine was given on seven occasions, each time with a further reduction of pain and an increasing range of movement. Where the intervals between the treatments were unusually long (four to five days) there was some tendency to retrogression, but the ultimate result was a complete and so far permanent restoration. Two other similar cases have given equally good results, one of them requiring only three sittings.

CASE 3.—Fibrositis and chronic villous arthritis. Long history with periods of remission following spa treatment, but gradually getting worse. Complete freedom from pain in knees with one treatment, the first time they had been painless for years. One knee has now remained free from pain for six months, but the other has relapsed owing to a fall and now is having daily either ionisation or massage with histamine. There is a very gradual improvement. In the same case a very severe fibrositis of the entire back is likewise yielding to similar treatment, but this is a case in which repeated applications appear to be required, something like 200 treatments having been given to the back and knee. After each sitting there is definitely a decrease in the pain, but there has not been the dramatic result which is got in the majority of cases.

CASE 4.—Osteo-arthritis of the left hip. Long history with much treatment at various places, but never freedom from pain. Completely free from all pain after the first application by ionisation, and could demonstrate the improvement by climbing stairs properly for *the first time* in many years. Was given seven further treatments and now, after four months, reports a continuance of the benefit.

CONCLUSIONS

(1) Histamine has a definite place in the treatment of fibrositis and neuritis, and in all chronic rheumatic affections associated with pain and limitation of movement. (2) With histamine it is possible completely to cure fibrositis and neuritis, and almost invariably to decrease or remove joint pains in other suitable cases. (3) The process of ionisation with histamine requires unremitting attention during the whole of the sitting and, even more important, the tolerance of a given patient both as to time and milliampèrage varies greatly from day to day.

Clinical and Laboratory Notes

RETROPERITONEAL CYST

By H. L. GREGORY, M.B. Camb.
SURGEON TO HORNSEY CENTRAL HOSPITAL; AND

L. M. MAYERS, M.R.C.S. Eng.
PHYSICIAN TO THE HOSPITAL

A MARRIED woman of 31, nullipara, after 21 months' amenorrhœa, consulted one of us (L. M. M.) on account of abdominal pain of a flatulent griping character, which was aggravated since she had taken aperients.

She was found to have an abdominal tumour as large as a six and a half months' pregnancy. It was median in position, pyriform in shape, elastic in consistence, with no evidence of fœtal parts to be detected, and arose from the pelvis. Vaginal examination disclosed the fact that the uterus was in front of the tumour, which extended into Douglas's pouch and felt definitely cystic. There had been none of the subjective signs of early pregnancy, and the cervix uteri was not softened; the question of extra-uterine pregnancy was dismissed from consideration and a diagnosis of ovarian cyst was confidently made.

She was admitted to Hornsey Central Hospital, and after the usual preparation the abdomen was opened by paramedian incision. Attempts to deliver the cyst on to the surface were completely frustrated by the colon, which was tightly stretched and closely adherent over the front of it from the right iliac fossa to the splenic region. In the belief that it was the transverse colon separation was begun from below, dividing what appeared to be peritoneal adhesions and swabbing the bowel upwards, but there was so much bleeding from the vascular subperitoneal tissues that this could not be continued. The cyst was therefore tapped and emptied. The content was about 3 pints of dark chocolate-coloured slimy fluid, suggesting that recent hæmorrhage into it had caused the rather sudden onset of symptoms.

The cyst was unilocular, and after emptying, its wall became obvious and it easily shelled out of its surroundings, having no connexion with either ovary. When it was gone, we found that instead of transverse colon we had been dealing with the sigmoid loop, whose vascular supply passed upwards on the left face of the cyst, and that now there was about a foot with no mesenteric attachment. Resection and end-to-end anastomosis were done, and as the patient's condition was becoming bad, done very hastily. During the suturing pulse and respiration were imperceptible and the abdomen was quickly closed, after running an œsophageal tube per rectum to 6 in. above the anastomosis. By this time the assiduous efforts of the anæsthetist were rewarded, and she went back to the ward with a pulse of 160.

Subsequent progress was anxious, but steady. Saline solution was given by drip through the inserted tube for 48 hours. She was then able to sip ʒii–℥ss. For eight days she had nothing more by mouth than fruit juice, glucose, Russian tea, and paraffin, and during the first

12 days she passed fæcal fluid by the tube, which was then extruded. She has had no symptoms of obstruction nor any other trouble since.

No ovarian tissue was found in the cyst wall, which was uniformly thin. The lining epithelium was not microscoped. The cyst may have arisen from the parovarium and lifted the posterior layer of the broad ligament and pelvic peritoneum as it increased; if not, its origin is obscure.

AN UNUSUAL REACTION TO NIRVANOL

By Charles S. D. Don, M.D. Aberd., M.R.C.P. Lond.
HONORARY PHYSICIAN TO SALFORD ROYAL HOSPITAL AND TO THE ROYAL EYE HOSPITAL, MANCHESTER

The treatment of chorea by phenyl-ethylhydantoin was introduced by Roeder[1] in 1919, and numerous papers dealing with this have appeared in English medical literature.[2–9] This drug, better known as Nirvanol, gives rise in many cases to a morbilliform rash, pyrexia, and a rise in the pulse-rate; sometimes, as mentioned by Poynton and Schlesinger,[3] cervical adenitis, drowsiness, conjunctivitis, pharyngitis, slight œdema of eyelids and face, and headache may also be observed. Ashby[6] has observed incontinence of urine. The temperature may even rise to 104° F. and remain so for four to five days, and at times, as in the case reported by Sehestedt,[10] a secondary rash may appear when the patient is convalescing from the typical nirvanol rash. Lesigang[11] and Whitaker[9] were able to induce a mild pyrexia and a rash in cases which had had nirvanol previously by giving a single dose to such patients. Murray-Lyon,[2] Lesigang,[11] and others have observed idiosyncrasies to nirvanol, and Keller[12] reported a case with high fever, headache, scarlatiniform rash, swelling of face and mouth, enlargement of spleen and liver, jaundice, and diarrhœa. Jones and Jacobs[7] had one case which became comatose, with bleeding from the nose and gums and a pyrexia lasting 11 days, the temperature rising to 101° F.

In the large majority of cases nirvanol in ordinary doses may be used with confidence and without fear of ill-effects. In the case here reported the patient appears to have had an idiosyncrasy to nirvanol and the temperature rose to an unexpected height and persisted for nearly three weeks.

This patient, a girl of 11 years, who had never had nirvanol previously, was suffering from chorea of moderate severity; she was of average height, slightly under the average weight, and she had a well-marked mitral presystolic murmur. She was given 0·3 g. of nirvanol on Jan. 9th and again on the 10th, and on the 11th a scarlatiniform rash appeared on the chest, the face was flushed, and the temperature rose to 102·4° F., the rise lasting two days. Six days later, as the choreic movements had improved to some extent, she was again given 0·3 g. of nirvanol on three successive days, when it was stopped as a scarlatiniform rash had reappeared; the temperature rose to 103·6° F. The rash lasted four days, but the temperature continued to be elevated, rising every evening, sometimes to 105° F. and rarely below 103° F., dropping frequently to normal in the mornings. This continued for 19 days. The face was flushed and slightly swollen, a little like an erysipelas, and she had headache. The glands in the cervical region, the axilla, and the groin were enlarged, the spleen gradually increased in size, and the lower margin could eventually be felt 2 inches below the ribs; the pulse was always over 100, and the presystolic murmur completely disappeared. The child was drowsy but did not appear to be desperately ill at any time. The temperature remained permanently normal after the nineteenth day of pyrexia, and the enlargement of spleen and glands disappeared in the course of the following week. She was discharged two weeks later much improved. It was difficult to detect the presystolic murmur at the time of her discharge.

A blood examination did not show an increase of eosinophils at any time. Most writers have observed eosinophilia, although Marick[4] did not find it to be often present. Two blood cultures taken at the height of the temperature were sterile. Agglutination tests were negative. X ray of chest showed no lesion such as Jones and Jacobs[7] noted in the unusual case which they reported.

SUBCUTANEOUS EMPHYSEMA IN A CASE OF BRONCHIAL ASTHMA

By F. Churchill Davidson, M.C., M.B. Edin., D.P.H.

The patient, a girl 9 years of age, had an eight years' history of bronchial asthma, each attack usually lasting only 24 hours. On March 5th, 1934, at 2 A.M., during an asthmatic attack, she had a spasm of severe coughing during which she experienced a sudden sharp pain in the front of the left upper chest. The pain lasted only a few seconds and she fell asleep again. She slept until 8 A.M., and on waking found her neck was "stiff and painful." On examination it was found that there was extensive subcutaneous infiltration of air into the upper part of chest and back, both shoulders, both arms as far as dorsum of hands, the angles of jaws to clavicles, and both sides of lower half of face. The appearances of the neck resembled infective parotitis (which diagnosis was actually suggested by the child's parent). There was considerable tenderness over the area of swelling, and the typical crepitations of subcutaneous emphysema were easily palpable. The child stated that she felt "cracklings in the ears" when she swallowed. Physical examination of lungs showed those signs associated with asthma—generalised sibili, &c.; there was no evidence of pneumothorax or other pathological lesion. The child felt ill for 24 hours, with slight cyanosis, shortness of breath, a pulse-rate of 120, and a temperature of 100° F. The asthma was relieved quickly by a few doses of Ephedrine syrup, and recovery was complete in a week, the subcutaneous emphysema disappearing slowly and completely. X ray examination could not be arranged but the child was seen by Dr. R. C. Wingfield, Brompton Sanatorium, who confirmed the diagnosis.

From the history of this case it is evident that the air escaped from a rupture of alveoli of left lung into interstitial lung tissue, and from thence via mediastinum to the neck. There was no evidence of any rupture of intercostal muscles.

Camberley, Surrey.

MEDICAL SOCIETIES

FELLOWSHIP OF MEDICINE

DEBATE ON THE TREATMENT OF PEPTIC ULCER

At a special meeting of the Fellowship, held at Manson House, London, on May 30th, with Lord Moynihan in the chair, a discussion took place on the motion "that, in the absence of complications, surgical interference in cases of gastric and duodenal ulcer is unnecessary."

Dr. A. F. Hurst, in proposing, said that ten years ago the chairman contended that an ulcer of the stomach large enough to produce a crater demonstrable by X rays could not be cured except by operation. About that time the speaker saw the largest gastric ulcer in his experience, and as a challenge to the prevailing view, he decided to treat it by medical means, warning the patient that the treatment would take a long time. In three months the symptoms had disappeared, and for years afterwards they did not return. To be effective, however, medical treatment must be thorough and prolonged. Duodenal ulcer presented a more difficult problem than gastric ulcer, largely because the duodenum was narrower than the stomach, and slight swelling or spasm sufficed to cause obstruction. Nevertheless he found it very rare for a patient who had had an established ulcer for less than ten years not to get well under medical treatment. An exception to this rule was the familial type of case, in which hæmorrhage began early in life, and the only effective measure seemed to be a large gastrectomy. Some advocated operation in order to prevent hæmorrhage or perforation; but he had never seen perforation in a case in which the patient had had proper medical treatment over a sufficiently long time. It was also said that a poor patient could not afford the time spent on the medical régime. But unfortunately there was no rule which confined major surgery to skilled surgeons, and while in the hands of the latter the operative mortality averaged about 1 per cent., for the whole country it was about 5 per cent.—a very real risk to face.

Mr. A. E. Mortimer Woolf said that while he supported the motion as it stood, he did not think the converse was true—namely, that all peptic ulcers, in the absence of complications, should necessarily be treated by the usual medical means. It had not been his experience that perforation did not occur while the patient was having adequate medical treatment. The question of hæmorrhage was very difficult; on the whole, he thought, hæmatemesis in gastric ulcer was rare, and in the presence of such bleeding it was advisable to look for some other condition. Where there was evidence that an ulcer had involved a vessel, the hæmorrhage must be treated in the same way as bleeding anywhere else. The cases which he considered should be operated upon were: those with an anatomical deformity, such as pyloric stenosis, hour-glass stomach, or adhesions; those in which there was a suspicion, or at least a possibility, of carcinoma; and recurring ulcers. In a straightforward case of ulcer without complications he would not advise operation without first trying other methods. He had seen surprisingly good results in cases he had treated by duodenal intubation.

Dr. Robert Hutchison said that many years ago he had crossed swords with Lord Moynihan and said that many unnecessary operations were performed for duodenal ulcer. His change of view had come about from observing the admirable operative results obtained by Mr. James Sherren at the London Hospital—results not approached by any medical series. He was astounded that Dr. Hurst should say that every case of uncomplicated gastric ulcer which was properly treated medically would heal, and with proper care remain healed. In *Guy's Hospital Reports* in 1928 Dr. L. J. Barford described the end-results in 160 cases of gastric and duodenal ulcer treated at the New Lodge Clinic. For gastric ulcer the results were said to be satisfactory after five years or more in 39 per cent., and fairly satisfactory in 13 per cent., and one-third of these had recurrences. The duodenal ulcer cases were regarded as entirely satisfactory in only 41 per cent., and fairly satisfactory in 28 per cent.; there were 24 per cent. of recurrences, and more than half the latter had had to come to operation. At St. Thomas's Hospital there had been nine cases of dangerous alkalosis in patients undergoing intensive alkaline treatment, and one of them was fatal. Dr. Hutchison contended that patients who had been operated upon could live a freer life than those who had medical treatment, which, with its rigorous restrictions and regulations, meant a condition of invalidism, not health.

Mr. Herbert Paterson said he did not approve of duodenal intubation; it was based on unsound principles, and it accomplished nothing which could not be secured by ordinary dieting. He agreed with Dr. Hurst that medical treatment must be adequate, much of the so-called treatment of ulcer at the present day being merely haphazard. Ulcer required months, not merely weeks, to heal. In his own view very great care was needed by patients for at least a year after gastric operations; most of the failures were due to neglect of this precaution. Gastric ulcers could be healed under medical treatment, but he doubted whether the same was true of well-established duodenal ulcers. In three cases he had seen perforation in hospital while the patient was undergoing medical treatment, and some years ago he had followed up 180 cases which had had proper medical treatment, 107 of which (60 per cent.) had relapsed. He was convinced that the risk of operation was less than the risk of hæmorrhage and perforation, and he thought that at least 90 per cent. of cases of duodenal ulcer could be cured by a properly performed gastrojejunostomy, provided patients were properly advised about their subsequent diet. In the last 20 years he had had 11 medical men patients who preferred medical to surgical treatment, and 3 of them had had perforations, one with a fatal issue. The motion before the meeting was untenable for four reasons: (1) it was contrary to experience that a large ulcer would heal if treated medically; (2) duodenal ulcer seldom or never healed; (3) septic foci, in the appendix for example, must be removed surgically; (4) cases of achlorhydria needed gastrectomy.

Dr. Mather Cordiner maintained that every gastric ulcer would respond to medical treatment provided there was no question of malignancy. Often malignancy could be detected radiologically and in such cases medical treatment should not of course be attempted.

Dr. Ernest Young spoke of some cases with very large ulcers which he had treated by duodenal intubation. The longest time required for healing was six weeks.

Sir William Wheeler said that the good physician would not delay matters by treating medically a case in which medical treatment was likely to prove futile. The general public were largely to blame if they went to an indifferent surgeon or physician.

Dr. WALTER CARR believed that sooner or later all, or almost all, cases of gastric, and certainly all cases of duodenal, ulcer relapsed. A second relapse should always mean surgical interference. The only alternative was for the patient to submit to very severe restrictions for the rest of his life; and his own advice was that it was better to face the comparatively small risks of operation.

Mr. L. N. PYRAH said that in Leeds since 1926 there had been an increase in the medical treatment of ulcer, a decrease in the number of cases of chronic ulcer operated upon, and an increase in the number of perforated ulcers. The number of cases of hæmorrhage admitted to the wards seemed also to have increased considerably.

Dr. J. R. BELL (Melbourne) felt that there had never been enough amicable coöperation between physician and surgeon to secure the best possible results for the patient. He did not agree with those who said gastric ulcer responded better to medical treatment than duodenal ulcer; his experience had been otherwise. He had seen many patients suffering from unpleasant after-effects of gastro-enterostomy.

Mr. W. E. TANNER emphasised the importance of searching for a cause of these conditions, and expressed his belief that ulcers of stomach and duodenum had a microbial origin.

Dr. JACQUES SPIRA said he had shown these ulcers to be due to the action of a direct local irritant on the mucous membrane, and acting on these lines had secured uniformly good results.

The openers having briefly replied,

The CHAIRMAN said the point which needed real insistence was the inefficiency of medical treatment as generally carried out in this country. He was himself strongly in favour of medical measures. His figures showed that of five patients consulting him for surgical treatment, three were referred back to the physicians; though not infrequently some of them came back after medical treatment. Ulcers took a long time to heal; it was essential that patients should rest in bed, with restricted diet, and that the treatment should extend over a considerable time, and he thought that following Prof. H. Maclean's paper surgical aid had been less called for, perforations had increased, and deaths also. As for Dr. Hurst's statement that he had never seen a death from hæmorrhage or perforation while a patient was undergoing medical treatment, he could only reply that he had seen so many that he had lost count of them. Medical treatment was in fact more dangerous than surgical treatment. At the same time he rarely liked to operate until he was satisfied that non-operative treatment had been carried out as thoroughly as possible.

The voting showed the following result: for the motion, 70; against it, 73.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES

A MEETING of this society was held in London on May 30th with Dr. DAVID NABARRO, the president, in the chair, when a paper on

Venereal Disease in Literature

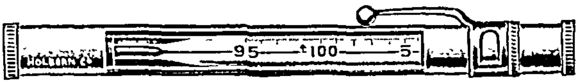
was read by Dr. J. D. ROLLESTON. He pointed out that the value of the allusions made by lay writers in various ages to venereal disease is indicated by the attention given them by numerous medical historians. In spite of statements to the contrary, there is no definite evidence in non-medical literature that syphilis existed in biblical times, classical antiquity, or the Middle Ages. In the sixteenth century the best known lay writers who refer to syphilis are Guicciardini, the historian, Erasmus, and Rabelais. In the Elizabethan age numerous references to syphilis are to be found in Shakespeare and other dramatists of the time. In the eighteenth century the prevalence and severity of syphilis are illustrated in the works of Voltaire, Casanova, Defoe, Fielding, Smollett, Steele, Swift, Gay, and Chesterfield. The belletristic literature of the nineteenth century contains for the first time descriptions of tabes and general paralysis (Heine, Alphonse Daudet, the De Goncourts, Guy de Maupassant, Ibsen, Conan Doyle, and Kipling). The antisyphilitic campaign in the French drama and novel at the beginning of the twentieth century was inspired by Alfred Fournier. Gonorrhœa, of which the first description is in Leviticus, dates from remote antiquity. Owing to its identification with syphilis for about two hundred and fifty years, the terms "clap" and "pox" in non-medical literature are used indiscriminately, the former being sometimes applied to tertiary syphilis and the latter to acute gonorrhœa. Chancroid is probably as old as gonorrhœa and was well known in classical antiquity and the Middle Ages.

A discussion followed in which the PRESIDENT, Sir D'ARCY POWER, Dr. H. J. NORMAN, Dr. PARKES WEBER, and others took part.

NEW INVENTIONS

AN IMPROVED CLINICAL THERMOMETER CASE

I HAVE designed a thermometer case which protects the instrument during the vulnerable periods of its career. Until clinical thermometers can be made so as to be absolutely indestructible, we must put up with breakage due to accidental dropping, though quite a number are broken in the thin case usually provided as a container. Moreover, these cases do not sterilise the thermometer. The container here illustrated is a strong metal tube longitudinally fenestrated, and lined with a Pyrex glass tube (the strongest glass known), the ends of this lining being ground to a watertight fit against washers at each end. The lower end of this tube has a light compression spring-loaded ferrule in which the bulb of the thermometer is held. The screw-cap at the other end presses the thermometer down into the tube and keeps it comfortably housed—in spirit or other antiseptic; a clip, of the fountain-pen type, keeps the case snug in one's pocket. Thus the thermometer is kept safe, sterile, and ready to hand. Owing to atmospheric pressure, when the thermometer has been extracted and the case laid on its side, the fluid does not run out.



The Holborn Surgical Instrument Co., Ltd., of 26, Thavies-inn, London, E.C.1, are the makers.

REVIEWS AND NOTICES OF BOOKS

Diabetes Mellitus

By I. M. Rabinowitch, D.Sc., M.D., C.M., F.R.C.P.(C.), Assistant Professor of Medicine and Lecturer in Biochemistry, McGill University; Director, the Department of Metabolism, the Montreal General Hospital. London: Macmillan and Co., Ltd. 1933. Pp. 246. 16*s.*

Dr. Rabinowitch has written this handbook to explain a simplified method of treating diabetes mellitus, and also to describe the high carbohydrate-low fat caloric diet which he has done much to popularise. The first few chapters give a good account of the different types of diabetes and the methods of diagnosis. The description of the action of insulin and of the various manifestations of hypoglycæmia is exceptionally clear. The advantages of the high carbohydrate-low fat caloric diet are then explained. As the amount of carbohydrate is very large, 250 to 300 g., it is unnecessary to weigh the different carbohydrate foods accurately. Dr. Rabinowitch therefore supplies his patients with wooden and paper models. A piece of wood 3½" by 3½" by ½" represents 1 oz. of bread, and one of 1" by 1" by ½" represents ⅓ oz. of butter. Similar models represent the various kinds of protein and fruits consumed. Dr. Rabinowitch always attempts to render the urine free from sugar by diet alone. He uses a ladder diet, starting with one day of starvation. The carbohydrate of the diet is rapidly increased, but the fat ration is very small, being only 50 g. Most of the patients in Montreal do not need insulin, but if sugar does not disappear it is always administered. The dose of insulin is assessed where possible by testing for sugar samples of the urine collected every four or five hours. Estimations of the blood-sugar are made in all cases of difficulty. The diet aimed at is C. 275 g., P. 80 g., and F. 45 g.—calories 1800. The patient is warned repeatedly against the danger of excessive quantities of fat; if, however, they are not content with the small amount of fat allowed, the carbohydrate of the diet is reduced and the fat increased.

The results with this treatment are said to be good, but it seems as ill-balanced as did the old diabetic diet of C. 40 g., F. 250 g.; and the advantages of a low fat régime with a moderately high carbohydrate—say 150 g.—and a moderate amount of fat—say 100 g.—must surely be made more clear before it is justifiable to require patients to submit to such a régime. The influence of any acute infection and also of chronic disease, such as gall-bladder infections, are well explained, and the rules laid down for the care of the feet in elderly people are very sound. But curious errors are made in speaking of the acetone bodies. Acetone is described as present in the urine, whereas Folin showed that this substance is not present in freshly passed urine, occurring only as a result of the decomposition of aceto-acetic acid; beta oxybutyric acid is described as diacetic acid, which is the correct name for aceto-acetic acid. The nitro-prusside test, which is actually more than ten times as sensitive for diacetic acid as it is for acetone, is recommended as a test for acetone, although it is said to be also a test for diacetic acid. Ferric chloride, described here as a test for diacetic acid, is not a sensitive test, and is often negative when the nitro-prusside test is positive, as Dr. Rabinowitch himself points out. Rothera's modification of the nitro-prusside test is not described.

The account of the sugar-tolerance test and the varieties of curves met with is valuable. The incidence of renal glycosuria seems much lower in Canada than in this country.

The book is of interest in that it gives a clear account of an unusual method of treatment. Some years will be needed, however, before it is possible to say whether the diet recommended has any substantial advantages over the more palatable one now in general use.

Röntgentherapie in Tabellenform

By Dr. Emmerich Markovits (from the Roentgen Laboratory of the Krankenhaus Stadt Armenheim in Budapest). Leipzig: Georg Thieme. 1934. Pp. 153. M.10.80.

The tables compiled by Dr. Markovits form an excellent guide to the methods of treatment by deep X ray therapy used in his clinic. The unit of dosage adopted is the biological "skin erythema dose," which the author regards as preferable to the international r unit which he finds in practice to vary greatly with different factors. For malignant disease the "Coutard-Pfahler" method is recommended. However effective this may be, it seems unfortunate that the names of two workers whose ideas are based on different conceptions of the biological response to radiation should be attached to any scheme of treatment.

The remarks on methods and dosage are introductory to a series of tables which include every disease which may be treated by X rays whether deep or superficial. The signs and symptoms, the indications for treatment, the benefits to be anticipated are set out with the technique advised, the possible complications, and the contra-indications. Some of the disorders included would not in this country be subjected to irradiation, but this is more commonly used for chronic infections in continental clinics than it is here, and good results are said to be obtained. The claims made by Dr. Markovits are not extravagant. When discussing the indications for irradiation in several forms of malignant disease he lays it down clearly that surgery is the method of choice, irradiation being considered only as a prophylactic treatment after operation or for inoperable cases. In respect of many conditions, notably ovarian tumours, it is stated that there are no contra-indications to treatment by X rays. Actually the general contra-indications, such as advanced cachexia or acute infection, have previously been noted, but it is misleading to ignore these entirely when specific diseases are under consideration.

On the whole this book represents a successful attempt to compress the fruits of much experience into a form which will allow others to benefit from it. The book ends with some useful plates and figures.

Dermatology and Syphilology

Practical Medicine Series. 1933. By Fred Wise, M.D., and Marion B. Sulzberger, M.D. Chicago: The Year Book Publishers. Pp. 458. $2.25.

This publication contains abstracts from the syphilo-dermatological literature of all countries during 1933. It is essentially a book for the specialist, although the introductory article by the editors on the treatment of acne vulgaris might well lure the general practitioner into the fold of the annual subscriber. There is ample scope for such a volume, for nobody, however voracious a reader, can hope to keep abreast of the literature and memorise even the best of the communications that annually advance these subjects. Some 200 articles and papers are abstracted, and a few lines of editorial comment and criticism are appended to some of them. The process is one which if further expanded would rob the literature of much of its terrors, and absolve the research worker from some tedious preliminary work.

The previous volume—1932—was the first to separate the subject of urology from this series, and the policy should make this issue decidedly more attractive to dermatologists. The table of contents has been enlarged by the addition of the article on acne mentioned above, a section on physical therapy, and another containing some interesting "experimental and investigative studies" among which German authors are overwhelmingly represented, Great Britain by only one, and France by none at all. A further addition is a supplementary bibliography with full references of some 180 contributions, American, German, Norwegian, and Italian, not considered quite worthy of abstraction for the purposes of this volume. French and British authors are again in the minority.

There can be no doubt at all that the idea of grouping the best publications and abstracting them annually in this way has much to commend it, not only because of the facilities afforded to busy workers who want to keep up to date, but also to save deserving authors from relative oblivion.

Combined Text-book of Obstetrics and Gynæcology

Second edition, revised, rewritten, and enlarged. By J. M. MUNRO KERR, M.D., F.R.F.P. & S. Glasg., J. HAIG FERGUSON, M.D., F.R.C.S. Edin., JAMES YOUNG, D.S.O., M.D., F.R.C.S. Edin., and JAMES HENDRY, M.B.E., B.Sc., M.B., F.R.C.P. & S. Glasg. Edinburgh: E. and S. Livingstone. 1933. Pp. 1100. 35s.

THE greater part of this text-book is devoted to obstetrics, of which a well-balanced account is given, in sufficient detail for the student. The second edition has been thoroughly revised and brought up to date. The chapters on toxæmias of pregnancy and puerperal sepsis are excellent, and an interesting final section on the causes and factors influencing puerperal mortality is included. Intercurrent diseases are discussed fully, and Prof. Charles McNeil contributes a useful chapter on "The Infant in the First Month."

Undue prominence is given to Schultze's and Byrd's methods of artificial respiration in the new-born; the illustrations of the first might have been omitted, since the authors themselves state that it is not now favoured, and recommend less violent measures. We regret to see the illustration of management of the perineum by the "British method" appear once more. The control of the head with the left hand passed from above between the mother's thighs would involve extreme discomfort for the obstetrician in prolonged delivery, and danger of sepsis for the patient. The short paragraph on septic abortion, a subject of great and increasing importance, is inadequate and gives no guidance in treatment. Otherwise, the obstetric section is well written and highly informative.

Gynæcology is treated more shortly. We have detected no omissions; the theories about the production of endometrioma are discussed, and rare conditions such as granulosa-cell tumours and Krukenberg tumours are described and figured. Mention might have been made of the importance of the Aschheim-Zondek reaction in the diagnosis of chorion-epithelioma. The relatively small space given to gynæcology necessarily curtails the amount of detail in the book.

Descriptions are given of all the important obstetric and gynæcological operations, with a final short chapter on radiology by Dr. J. Duncan White. The work is well illustrated by some 500 drawings and photographs.

Obstetrícia Operatória

By RAUL BRIQUET, Professor of Clinical Obstetrics in the Medical Faculty of São Paulo. São Paulo: Companhia Editora Nacional. Pp. 540.

THIS book, intended for students and practitioners of midwifery, is clearly written. The marginal headings, and the system of arranging the different operations in numbered steps, facilitates rapid reference. The illustrations, many of which are borrowed from well-known text-books, are good. The chapters on maternal and fœtal traumata, and on the indications and contra-indications to operation, are particularly useful. Certain omissions are noticeable—e.g., no mention is made of axis-traction forceps or of glycerin drainage. The chapter on anæsthesia contains 38 pages devoted to spinal anæsthesia, and only two on inhalation methods, under which heading only chloroform and ether are discussed; and gas-and-oxygen is not mentioned. In the description of the technique of blood transfusion no account is given of the preliminary grouping of the bloods, and the necessity for this is not explained. The book is marred by inaccuracies, of which a proportion only is included in a list of errata. Foreign words, in particular, are often misspelt. These errors render the book troublesome to read and diminish its value.

Practitioner's Library of Medicine and Surgery

Vol. VI. *Obstetrics and Gynæcology.* Associate Editor: LUTHER K. MUSSELMAN, B.S., Ph.D., M.D., Associate Clinical Professor of Obstetrics and Gynæcology, Yale University School of Medicine. London: D. Appleton-Century Company. 1934. Pp. 900. 50s.

THIS volume is the outcome of the collaboration of 14 teachers who have each written a monograph on one aspect of midwifery or gynæcology: 560 pages are devoted to midwifery, 278 to gynæcology, and 58 to the index. The preface states that the book is intended for the use of the man in general practice, and this doubtless accounts for the fairly extensive clinical review of obstetric symptomatology and treatment, and for the compression of the gynæcological matter into small space.

The work appears to reflect clearly the present-day practice of midwifery and gynæcology in the United States of America. On the whole the practice recommended is that in common use in this country, but in a few places the teaching would be unacceptable here. Under the heading of toxæmia of pregnancy Dr. Musselman gives a good clinical picture of the various manifestations of this condition. He reviews the usual methods of treatment of eclampsia and pre-eclampsia, and points out the good results of expectant treatment as against the poor results of accouchement forcé. At the conclusion he recommends the practitioner always to adopt expectant treatment as giving the best results for both mother and baby, while admitting that in a good hospital a specialist will get excellent results from emptying the uterus immediately after the first eclamptic fit. Under the heading of pathological pregnancy are grouped many complicating conditions. Here we notice a certain inclination to advise the woman suffering from defects to put up with them rather than to seek treatment during pregnancy. For example, in gonorrhœal infection of the cervix local treatment is not advised, and even if the condition is accompanied by cervical erosion or warts of the vulva the main emphasis seems to be laid on the instillation of silver nitrate drops into the infant's eyes after birth to avoid the consequences of neglect of treatment of the mother. Each section is supplied with full references, and a good subject index is supplied.

1. Adam's Ancestors

By L. S. B. Leakey, M.A., Ph.D. London: Methuen and Co., Ltd. 1934. Pp. 244. 7*s.* 6*d.*

2. This Progress: The Tragedy of Evolution

By Bernard Acworth. London: Rich and Cowan. 1934. Pp. 334. 7*s.* 6*d.*

1. Dr. Leakey became famous two or three years ago by his discovery in Tanganyika of the remains of a very primeval man fairly similar to modern *Homo sapiens* and probably in his direct line of descent. In this book he gives a clear and readable discussion of man's immediate ancestry and of the various kinds of men—e.g., *Palæoanthropus neanderthalensis*—which have disappeared. Our knowledge of them comes as much from the remains of their cultures as from their own bones, and a large part of the book is taken up with the description and classification of their imperishable stone implements. Modern research has gone a long way since we knew of nothing but palæoliths and neoliths, and Dr. Leakey's functional tests of these old tools are particularly impressive; he tells us, for instance, that in Africa he skinned and cut up a gazelle in 20 minutes with a tool about 25,000 years old and less than 2 inches long. He also describes from his own experiments how the various implements may be made. It is a good book and cheap, and it should be widely read.

2. Mr. Acworth knows so little of evolution that he regards it as inconsistent with Christianity, and so little of Christianity that he finds it irreconcilable with evolution. In this schoolboy dilemma he, wisely enough perhaps, chooses Christianity, and says that "the theory of evolution is a faith founded in atheism, leading its adherents to nihilism" and much more of the same sort.

Diagnostics Urgents—Abdomen

Second edition. By H. Mondor, Professeur agrégé à la Faculté de Paris; Chirurgien de l'Hôpital Bichat. Paris: Masson et Cie. 1933. 2 vols. Pp. 1064. Fr.125.

This treatise is concerned solely with acute abdominal diseases of such a nature that, if surgery be refused, the patients die in a few hours or days. Surgeons will find it of absorbing interest. Every conceivable emergency is considered fully and very clear accounts are given of signs and symptoms. The author's method is to give a general description and then to drive home the lessons he wants to instil by the clinical notes of actual cases. Not all of them are personal ones; several are from classical sources. Prof. Mondor takes no narrow view of his subject. He has searched widely in the literature of this branch of surgery and gives authority for all his statements.

The general make-up of the book and the illustrations reach a high standard. There is perhaps a little unnecessary reiteration, but this at least serves to emphasise the truth of the teaching that the author wishes to drive home. The book represents a store of knowledge of the syndromes of acute surgical abdominal disease.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

V.—SEGREGATION OR STERILISATION?

The reduction of those physical and mental infirmities which are commonly regarded as hereditary can be viewed from different angles by the biologist and the administrator. To the biologist, the problem presents itself in panoramic simplicity as a racial problem. The national birth-rate, he observes, is falling and we are within measurable distance of reaching a stationary or even a declining population. He notes the phenomenon of the differential birth-rate and the fact that the poorest and socially most submerged fraction of the population has the highest fertility and will therefore contribute to the next generation a fraction larger than that which it now constitutes. To the biologist, sterilisation commends itself as a simple, logical, medically feasible, and humanitarian measure whose racial effects can be made to resemble those which, in the past, were more brutally achieved by natural selection. The measure appears to him no less applicable to those mental defectives who owe their infirmity to heredity than to other victims of morbid inheritance.

The administrator, however, sees the problem from a very different angle. Less concerned with biological than with social considerations, he is responsible for the care and protection of individual mental defectives. He is keenly aware that the institutional provision at present available for these is, in many areas, lamentably inadequate. He recognises that the approved sterilising operations leave the defective's antisocial proclivities wholly unchanged and that if a defective stole, committed sexual offences, or made a nuisance of himself before sterilisation, he would continue to do so afterwards. Improved ascertainment and an amplifying of existing institutional accommodation are for him the first requirements to be satisfied. What compromise, if any, can be reached between these two views?

SEGREGATION HAS NEVER BEEN PROPERLY TRIED

The facts of the matter are as follows: according to the annual report of the Board of Control for 1932, some 35,000 mental defectives are in institutions under the Mental Deficiency Acts. The total number of mental defectives in England and Wales has been estimated by the Wood Committee as 300,000. This committee has further recommended that institutional provision be made for 100,000, or one-third of this total. The committee further advocated what they termed a "new conception" of the function of the institution and the colony for mental defectives. These should no longer be regarded as permanent residences for mental defectives but rather as training schools, wherein the most would be made of their limited capacities and aptitudes with a view to equipping them to live useful lives under supervision in the general community. The institution, according to a simile employed by the Wood Committee, should be regarded, not as a stagnant pool, but as a flowing lake, through which should pass a stream of defectives who would be stabilised, trained, and subsequently placed in the general community. Like sterilisation, this conception was first put into practice in America, particularly in the work of Fernald to whom we owe the conception of the institution as a socialising force.

That the principle of sterilisation can be usefully adapted to this view was recognised as early as 1929 in the Annual Report for 1928 of the Board of Control which contains the following passage:

> "Roughly speaking, out of 300,000 mental defectives in England and Wales, one-third will require institutional provision and two-thirds some form of community care, that is, care outside an institution. It is in the case of the latter that the risk of procreation arises and the case for sterilisation, if such a case exists at all, is strongest."

This view has been adopted by the Brock Committee which has recommended the creation of legal facilities for the voluntary sterilisation, subject to appropriate safeguards, of certain mental defectives. The measure, however, is clearly limited to those defectives who, apart from the risk of their procreation, are fitted for life in the general community. That is to say, it is wholly unsuited to those mental defectives who have antisocial tendencies which could not be controlled under the conditions of supervision or guardianship which have been specified in the Mental Deficiency Act.

SAFEGUARDS

There is then no antithesis between segregation and sterilisation. Each is necessarily incomplete and ineffective without the other. Segregation alone has never been applied to the extent of making it eugenically effective, nor could it be so applied without such expense as even an enlightened public opinion might hesitate to incur. But sterilisation would also fail of its purpose unless combined with a far larger and more intelligent use of segregation than is at present the case. As safeguards against abuses and misuses the Brock Committee suggest that an application for sterilisation should be supported by two medical practitioners, one of whom should, if possible, be the patient's family doctor and the other a practitioner on a list approved by the Minister of Health. In all cases in which the patient is capable of giving consent he should sign a declaration of willingness to be sterilised, and one of the two medical recommendations should include a statement that the effect of the operation has been explained to the patient and that, in the medical practitioner's opinion, he is capable of understanding it. If the practitioner is not satisfied that the patient is competent to give a reasonable consent, the full consent and understanding of the parent or guardian should be obtained, and if the applicant is married, he or she should be required to notify the spouse of the application.

It would be undesirable as a general principle to make discharge from an institution conditional upon sterilisation; for apart from being a form of "veiled coercion," this would make it possible for the parent or guardian, by refusing consent to sterilisation, to keep a defective permanently in an institution.

Provided then that sterilisation is used with discrimination and is not forced upon the defective or his relatives against their inclinations and scruples, it can clearly be used as an auxiliary to segregation in such a way as not to interfere with the fulfilment of the recommendations of the Wood Committee relating to the creation of increased facilities for segregation.

THE QUESTION OF COMPULSION

"What is the use," it is sometimes asked, "of limiting proposals for eugenic sterilisation to voluntary measures? These will never be adopted by the very people whose fertility we are most anxious to restrict. Such are incapable of using contraception, still less sexual abstinence. The only way to deal with real slum types in any big town is to sterilise them willy-nilly." This argument has been increasingly heard since the publication of the Brock report. Though the German Sterilisation Act has only been in force since the beginning of the present year some information about its workings is already available. Nine conditions are specified which justify voluntary or compulsory sterilisation. These include schizophrenia and manic-depressive insanity, disorders which, along with seven other morbid conditions, are notifiable much as are certain infectious diseases in this country. A person in whom a diagnosis of any of these nine conditions has been made becomes a potential candidate for voluntary or compulsory sterilisation.

But the diagnosis of mental disorders is not as simple and straightforward a business as the diagnosis of most common physical ailments; both the standard and the terminology employed by psychiatrists differ in different countries and even in the same country. Since the passing of the Sterilisation Act it has been noticed that German doctors hesitate to diagnose schizophrenia and manic-depressive insanity, preferring to use other and less compromising diagnostic labels. People are beginning to be afraid of entering public institutions for the treatment of mental disorder, wherein they may be compulsorily sterilised before discharge; and they are inclined to conceal important elements of their pedigrees which might substantiate these diagnoses. If this goes on it will put an end to any open inquiry into the genetics of mental disorder which, above all things, depends on the submission of accurate pedigrees. More important than all this in the life of the community is the fact that the use of sterilisation as a compulsory measure will inevitably cause a stigma to be attached to the operation in exactly the way that would happen if it were used as a weapon for punishing crime. An individual would have to exhibit very undesirable characteristics to be compulsorily sterilised; and if such a measure became law people would hesitate before coming forward voluntarily for sterilisation, lest they be tarred with the same brush. The German propaganda is distinguishing with great care between the eugenic and the punitive.

It has moreover been found, in those States in America where voluntary and compulsory clauses exist, that superintendents of institutions will not incur the unpleasantness of applying compulsion unless they are supported by public feeling. But where a favourable public feeling exists, people will avail themselves of sterilisation voluntarily. Where the measure lacks public support no one gets sterilised, even if compulsory clauses are in force; where public support for sterilisation is forthcoming compulsory clauses are unnecessary. It can therefore be said that though occasional cases can undoubtedly be found to which compulsion appears applicable, the advantages of formulating coercive clauses to meet them are entirely outweighed by the accompanying disadvantages.

THE LANCET

LONDON: SATURDAY, JUNE 9, 1934

SCHOOL EPIDEMICS

It is not easy for the school medical officer to handle the problem of infectious disease in a way that will please everyone. Caution in his methods of isolation leads the parent to complain that his money and the child's time are being wasted; laxity lays him open to censure. The old-fashioned parent seemed content to look upon the public school as a place where the character and physique of his children were hardened and prepared for the larger world. The weakest went to the wall and the survivors emerged morally and physically "salted." The parent of to-day expects a large measure of individual care, both as regards mind and body, to be given, and unflagging efforts are made by school-masters, medical officers, and others to provide this care. Nor is the effort restricted to individual schools and their officers. The modern school doctor exchanges frequent notes with his colleagues elsewhere on matters of school hygiene. For some years past the Medical Research Council have had a special committee for the investigation of school epidemics; 30 large public schools coöperate in keeping this committee continuously informed of what is happening in the schools. Already valuable information has been acquired. Special laboratory investigations have been carried out using the material provided by those schools. Among the more important results have been those submitted by J. A. Glover and F. Griffith on streptococcal infections in schools. Much light has been shed on the spread of conditions due to infection with hæmolytic streptococci; the cumulative effect of nasopharyngeal epidemics is recognised, and that an epidemic of colds may lead to an outbreak of sore-throat, which in its turn may give rise to otitis or mastoiditis. An epidemic of scarlet fever may be concealed in such apparently modest manifestations.

There is instruction to be gained from contrasting girls' schools with boys'. As compared with boys, girls have had less than half the incidence of otitis media and pneumonia, and only one-eighth the incidence of sinusitis. This may be ascribed in part to the greater care and supervision which girls receive, but is probably more closely connected with the better sleeping accommodation at the girls' schools. Most modern observers have emphasised the importance of dormitories as breeding grounds for epidemics. There is little doubt that better dormitory conditions and less overcrowding would improve the hygienic reputation of some of our public schools. In this direction, at least, the schools themselves have an ample field for effort, and it is but fair to say that most of them are doing as much as their finances allow.

One of the outstanding things in modern school hygiene has been the success of the preparatory schools in achieving perfect health conditions. The public schools might well complain that the efforts and precautions of many of the preparatory schools have been too successful. Boys and girls go on to the big schools in a state of epidemiological innocence and with little preparation for guerilla warfare with microbial infection. The public schools have thus to bear the brunt not only of epidemics of their own age-group but of others which, if they must be faced, might well have been faced earlier. It is not uncommon for a boy or girl to catch measles, whooping-cough, and scarlet fever in addition to minor infectious complaints during the three or four years at public school, and even if the scholar passes through these without giving personal cause for anxiety the parent may become restive at the loss of school time due to the interference in routine which must accompany epidemics. Artificial immunisation has little to offer. Its modern triumph is against diphtheria, a disease rarely met with in better class schools. The public hears vaguely that scarlet fever and measles can now be prevented or aborted, and though this is true it would be well-nigh impossible to apply the new methods to school life. The only solution of general application is the one attempted in all well-managed schools—to keep the individual boy or girl in the best possible state of health and to make every effort to prevent threatened epidemics from gathering headway. Infection being accepted as inevitable, the child encounters it in the best possible position to overcome it with his own defences. We hope it may not be taken as a counsel of despair if we suggest that until the study of infection has reached a more advanced stage it would be well for the parent (even if he is a doctor) to look upon the public schools, with his grandfather's eyes, as a place where a boy can learn to make his first trials against the struggles and hardships of life, not forgetting that this applies as much to the attacks of microbes as to the chastenings of his fellows.

PERIPHERAL VASCULAR DISEASE

The relief which surgery can afford in certain disorders of the peripheral blood-vessels has aroused a growing interest in the selection of cases suitable for operation, and consequently in the pathology of arterial obstruction. The study of patients showing the various manifestations of peripheral vascular disease has exposed our lack of knowledge of the processes which bring about changes in colour, temperature, and sensation in the affected extremities, and the need to develop methods of investigation which besides giving reliable information with regard to the state of the arteries, arterioles, and capillaries, will also indicate the value of various forms of treatment. Steps in this direction are being made in centres of clinical research in this country and in the United States, and workers in the vascular disease clinics established respectively in Chicago and in Cincinnati have recently described their routine methods of examining patients.

G. De Takats and W. D. Mackenzie, of Chicago, lay particular stress[1] on the value of the tests in determining the lowest level at which amputation may be performed with a good prospect of sound healing, but the tabulated notes of cases of organic and spasmodic vascular disorders indicate how often amputation may be avoided by carefully planned physiotherapy, exercises and other measures, such as protein shock, designed to encourage the peripheral circulation. In every case a note is made of the volume of the pulse in the main vessels of all four extremities; the surface temperature is registered at several points, and the elasticity of the main vessels is tested by means of the Pachon oscillometer. These tests provide information about the condition of the arteries; the smaller vessels being examined by observing the variations in the colour of the skin as the result of changes in posture, and also by the cutaneous reaction to the injection of a small quantity of histamine acid phosphate. X ray examinations for calcareous degeneration and also after injection of iopax, skiodan, or thorotrast are made in every case, and among the investigations to be carried out only under special circumstances is mentioned excision of a short portion of one of the smaller arteries for histological examination. This may seem a drastic procedure in a limb already suffering from the effects of arterial damage, but it is essential that the details of the morbid processes in the vessel walls should be ascertained in order to correlate the clinical findings with the true pathology, and there is evidence that excision of a portion of a diseased artery may not be as harmful as it sounds, and may in fact be beneficial.

The keynote of the communication by M. R. Reid,[2] of Cincinnati, is the conservative treatment of the complications of vascular disease, and especially the alternatives to amputation for gangrene. From an intensive study of his clinical material he concludes that arteries may become occluded by a gradual process without any noticeable change in the tissues supplied by them, but that when a limb in such a critical condition is exposed to cold, is attacked by infection, or has another of its arteries occluded *suddenly* by embolism or thrombosis, gangrene is extremely likely to supervene. He believes that the difference between gradual and sudden occlusion of the arteries is to be explained by the element of vasospasm accompanying sudden blockage, and he devotes the greater part of his paper to the consideration of various measures which may be adopted to tide the patient over the critical period immediately after the occurrence of the block and until the supply of blood can be readjusted to the demands of the tissues for it. In addition to good nursing, care of the skin, application of warmth, attention to the posture of the limb, and administration of large quantities of fluid, Reid advocates a new piece of apparatus designed with the same object, that of improving the peripheral circulation in sclerotic arteries so as to avoid amputation. It consists of a chamber shaped like a large boot which surrounds the limb, and is connected to a motor-driven pump capable of producing alternating positive and negative pressures within it. The leg is treated in a slightly elevated position, and the machine is set so as to produce a negative pressure of 80 mm. Hg alternating with a positive pressure of 20 mm. Hg, the duration of a complete cycle being about 30 seconds, and a single treatment lasting on the average about 20 minutes. The machine is sold under the name of the Pavaex Treatment Unit, Pavaex being a portmanteau word for passive vascular exercises. The value of this apparatus is established by the results obtained in 69 patients, all with advanced arterial disease, and many showing the premonitory signs of gangrene or even fully developed gangrene of one or more digits. The most noticeable effect, which occurred in every patient, was that the surface temperature of the limb rose and remained up for several hours after the treatment. When treatments were repeated at frequent intervals it was possible to maintain this rise of temperature indefinitely, and as the effect is due presumably to increase of collateral circulation, the relief of pain and the improvement in the nutrition of the limb which accompany it are readily accounted for.

The reference to spasm in the distal vessels as a result of embolism or thrombosis of an artery recalls the work of R. Leriche and P. Stricker,[3] who have recorded great improvement in the peripheral circulation following excision of the occluded segment of the artery. They explain this remarkable observation by supposing that the inflammatory changes in the vessel wall at the site of occlusion stimulate the sympathetic nerves in the tunica adventitia, thus causing peripheral vasoconstriction. This explanation revives the hardy controversy about the justification for peri-arterial sympathectomy, and though anatomists still have nothing to say in its favour there are many surgeons, prominent among them being Prof. Archibald Young, whose confidence in the operation remains unshaken. Prof. Young, in an account[4] of his own experience of peri-arterial sympathectomy in the treatment of a large number of circulatory disorders, concludes that its value has been proved clinically, and that "it is for the anatomist and the physiologist to explain the results on whatever basis they choose." Prof. Young supplies also an interesting account of the manner in which our knowledge of the nervous control of the blood-vessels has gradually been built up, and refers to a little-known series of experiments carried out by Lister in 1857 which can be recognised as a natural prelude to the work of Gaskell, Langley, and Bayliss. The interest of surgeons in the problems of vascular disease is more intense now than it has ever been before, and there is reason to hope that, given clinical methods of investigation accurate enough to indicate the value of various methods of treatment, surgery may again prove a powerful instrument of research.

PROGRESS IN PSYCHIATRY

A REVIEW of any one disorder tends to incorporate much of the history of similar conditions, and Dr. A. J. LEWIS, in his recent review of melancholia [1] accuses himself of writing something like a history of psychiatry. By such a fault, if it be one, psychiatrists are so much the richer. It would be impossible, however, not to have made this welcome mistake seeing that the affective disorders have only been clearly differentiated from the schizophrenic psychoses within the last hundred years. Vogel (1724–74) classified *morbi mentis* into six: mania, melancholia, fatuitas, stupiditas amentia, and oblivio. In 1849 in his Croonian lectures John Conolly of Hanwell, the champion of "no restraint," could still describe mania and melancholia as the two chief types of mental disorder; but he saw that stupor and apathy, of a type now regarded as schizophrenic, were definitely of another order. To-day the discussion whether psychotic depressions and neurotic depressions can be separated still continues, though Dr. Lewis himself shows that he believes attempts at rigid segregation may defeat scientific accuracy.

The cleavage between those who have attempted to explain or classify mental disease, and those who have aimed at giving accurate clinical descriptions, is clearly seen in Dr. Lewis's review. The German school are typical of the former, Esquirol preeminent in the latter; while Maudsley occupies a distinguished position midway. There have been endless theories, from those of Hippocrates, who divided mental disorders into four (mania, melancholia, paranoia, and phrenitis), and Galen, with his emphasis on a superfluity of black bile in melancholia, down to the present day. Riverius, of Montpellier, in the sixteenth century insisted on a proximate cause, a poison generated in the body, which can be taken up and developed best in the "atrabiliar constitution," and thus preceded those who at the present time seek in the disorder for some fundamental biochemical abnormality. John Brown in the eighteenth century, viewing insanity as a disease not of a single part but of the whole body, was in a sense the father of modern theories. Paracelsus (1658) and van Helmont (1707) suggested that melancholia springs from anger and fright and that these arise in some way from the stomach—a view which recalls Stransky's unconfirmed theory of 20 years ago that the vegetative nervous system and the endocrines are largely responsible for the condition. English physicians before Pinel were accused by him of confusing the issue by their theories—a taunt which can hardly be levelled at the German school led by Griesinger. This school produced Kahlbaum, who showed how the morbid affect could account for all the mental signs in melancholia but not for those in primary dementia (dementia præcox), and Kraepelin, who built the theories of others into the most stable elements of modern classifications. The French school is notable for Pinel, who was the first pleader for more humane treatment of the insane; Esquirol, who combined interesting theories with a genius for clinical observation; Falret, who first described *folie circulaire* in 1855, and whose influence on Kraepelin, Dr. Lewis says, "may be safely assumed"; and Morel and his successors, who first drew attention to constitutional and inherited factors, and must thus be placed, chronologically, before Kretschmer. Finally, tribute is paid to Adolf Meyer, whose emphasis upon the psychobiological individual reactions has influenced psychiatrists' conceptions profoundly. Bonhoeffer's description of exogenous types of reaction belongs to the present century, as do the theories of the psycho-analytical school.

Dr. Lewis reminds us that his exhaustive and illuminating survey hardly deals with therapy. The history of mental disorder has been marked by the efforts of the exorcisers and believers in witch-magic—a fact which was only poorly concealed by our ancestors in the medical art. Thus to quote again regarding Brown: his theories led him to attempt to excite the opposite emotions in his patients, and the depressed melancholics were subjected to the cruellest alarms. Avicenna, in the eleventh century, was the father of the whirling chair. Electricity was used in the eighteenth century, and warm baths for mania and cold baths for melancholia were advised at the same time. It is interesting to note that Pargeter, in the same century, recommended snuff, on the assumption that it aids the removal of lymph from the upper respiratory tract, and that the sneezing stimulates the nervous system. Dr. Lewis omits any discussion of the "humane" aspects of treatment, but these have been fully and frequently considered elsewhere.

THE BIRTHDAY HONOURS

ON page 1256 will be found the names of the members of the medical profession who have received honours on the occasion of the King's birthday, but in addition to those who have a place on the Medical Register there are others in the list whose work has been discharged either in close alliance with medicine or in fields where their activities make for the promotion of medicine. Everyone will recognise among these as one deserving of public honour Miss A. F. Lloyd Still, whose services alike as president of the International Council of Nurses and matron of St. Thomas's Hospital have been of high importance. Miss Lloyd Still becomes D.B.E. Among the new knight bachelors will be found Captain Ian Fraser, M.P., chairman of the Executive Council of St. Dunstan's, whose zealous activity on behalf of the blind commands admiration. Miss Nancy Stephen, in connexion with the Red Cross Society, has laboured for blinded ex-soldiers in the Commonwealth of Australia and receives the O.B.E., and the same distinction falls to Miss Ethel Rose Collins, R.R.C., principal matron, Queen Alexandra's Imperial Military Nursing Service. The M.B.E. has been awarded to Mr. Norman Casey, superintendent of prisons in Fiji, and Mr. Alfred Nicholls, superintendent of police and prisons at St. Helena. Mrs. Ann Maria Greenwood, matron at the British Military Families Hospital, Hyderabad, receives the M.B.E., as also do Miss Sarah Jane Lambert, R.R.C., county nursing superintendent and inspector of midwives, Isle of Wight, and Miss Mabel Elsie Wolff, inspector of midwives, Sudan. The Kaisar-i-Hind Gold Medal has been awarded to Miss Lena Benjamin, superintendent of the American Baptist Mission Hospital, Madras; and to Mrs. Jeenabai Duggan, of Bombay. To all the medical men and women in the honours list, and equally to those whose coöperation in their work has been signalled out, we offer congratulations.

ANNOTATIONS

THE SHENLEY MENTAL HOSPITAL

IN opening this hospital last week, H.M. the King spoke of recent advance in ideas governing the treatment of mental disease and of the opportunity offered by the Mental Treatment Act, 1930. As far as this country is concerned the Shenley Hospital represents a new development; treatment of the poorer classes in Middlesex is now to be undertaken in surroundings and under conditions which have previously only been open to the middle and upper classes. At all mental hospitals of recent years the villa system has been adopted when new building was required. These plans have been fostered and encouraged by the Board of Control, under the chairmanship of Mr. L. G. Brock. But the villas have always been built in proximity to the older buildings and have shared their drawbacks. Too often patients in new villas have had to be transferred to wards in older wings with airing-courts surrounded by brick walls. Shenley will house not fewer patients than the average county mental hospital; ultimately there is to be accommodation for 2000 without overcrowding, all living in communities of not more than 45 patients per unit. The account which we gave in our last issue (p. 1198) of the actual buildings showed how every new and up-to-date principle in psychiatry has been embodied in the hospital. Every member of the profession, whether specially interested in psychological medicine or not, will watch with keen interest the results of the Shenley Hospital; for the principles therein realised spring from the recognition that the mental patient is worthy of as close study, sympathy, and encouragement as his neighbour whose affliction is only physical. In time other counties will be enlightened enough to build hospitals after this new pattern.

THE NEW GERMAN VACCINATION LAW

THE Home Secretary of the Reich has promised a revision of the Vaccination Law in force which dates from April 8th, 1874, and as it is taking him longer than he expected to draw up, and time presses, he has issued[1] instructions to public vaccinators how to carry on in the meantime. Under the 1874 law primary vaccination was compulsory within the first year of life, apart from medical exemption, and a revaccination in the twelfth year. The instruction was to make four shallow cuts not more than 1 cm. long and at least 2 cm. apart. The prescribed routine technique is now to make two shallow cuts only 3 mm. long and at least 2 cm. apart on the right upper arm, the left upper arm being reserved for revaccination. Other sites are permissible if preference is expressed for them. Vaccination is commonly to be carried out at regular sessions specially arranged for the purpose, but the public vaccinator must vaccinate at other times and places should parents or guardians insist upon it. He must at all times be accessible to parents or guardians who observe anything unusual after the vaccination. He is given a good deal of discretion as to postponement for one or two years. In every case inquiry has to be made as to the existence of infectious illness or skin eruptions of any kind at the vaccinee's home and whether the vaccinee is subject to any skin complaint or has any liability to convulsions. Special emphasis is laid on the importance of postponement should there have been inflammatory disease of the central nervous system in the household or any story of mishap after a previous vaccination in the family, whether well authenticated or not. Finally, emphasis is laid on the duty of public vaccinators to instruct the population in their neighbourhood about the nature and purpose of vaccination by every means within their power.

THE SUCCESS OF SANATORIUM TREATMENT

AT first sight it would seem to be a simple enough task to measure the degree of success which attends sanatorium treatment. In reality, as Dr. A. S. MacNalty has pointed out,[1] it is extremely difficult, for physicians have different standards of selection and classification of patients, the after-histories of patients have not been collected for a sufficient number of years, and the data at present available are very scanty. Still more difficult is it to determine the influence that the development of sanatorium methods has had not only upon the lives of the patients but on the general mortality for which tuberculosis is responsible. It is probable that numerous factors have contributed to the decline in the tuberculosis death-rate observed for many years. To isolate the part played by one possible influence is a precarious task. Using the vital statistics of the provinces of Canada Dr. Madge Macklin has recently made an attempt to answer the question.[2] For each of the seven provinces she has determined the tuberculosis death-rates in 1921–29, by age and sex, and has placed alongside them the sanatorium provision made in each area, the latter being expressed in two ways: first with respect to the number of sanatorium beds per 100,000 of the population, secondly with respect to the number of beds per 1000 deaths from tuberculosis. Using the second criterion as the better measure, there appears to be a definite relationship between the accommodation existing for the treatment of patients and the total death-rate from the disease. Those provinces having the best sanatorium facilities have the lowest tuberculosis death-rate, and in 1901, before the introduction of sanatorium treatment, the same differences between the mortality-rates of the provinces were not apparent. The provinces making the largest provision for sanatorium treatment have recorded the greatest improvement in the death-rate. Dr. Macklin therefore suggests that the considerable expense which sanatorium treatment entails is justified, both for the better chance of recovery that it affords the patient and still more for the protection from infection which it confers upon the much larger group outside. She does not overlook the fact that this conclusion is justifiable *only* if all other factors contributing to tuberculosis mortality are identical in the groups compared with respect to sanatorium treatment. This proviso is vital to her thesis and, indeed, in her comparison of the tuberculosis death-rates with beds per 1000 tuberculosis deaths it is difficult to be sure which is the cart and which the horse. For instance, if the provinces made approximately equal provision of beds—and as measured per 100,000 of population the differences are not very large (except in Quebec)—the area with the lowest death-rate in 1921–29 and the greatest rate of improvement must inevitably show the highest number of beds per 1000 tuberculosis deaths, although sanatorium provision may have played no part in the decline. It seems impossible to prove the complete absence of other factors contributing to the results shown—the fact that the provinces differ in one aspect of public health activity suggests that they may differ in others. The assumption that sanatorium treatment is the only variable appears a bold one: without it the case remains unproven.

CORTICAL EXTRACT BY MOUTH

EXPERIMENTS recorded by A. Grollman and W. M. Firor[1] again raise the question whether extracts of suprarenal cortex can usefully be given by mouth to patients with Addison's disease. A dried cortical extract was used for many years at the Mayo Clinic with some apparent benefit as part of the Muirhead regimen; H. S. Stannus last year reported a case in which dried cortex by mouth seemed for a time to be more beneficial than injections of cortical extract; and J. M. Rogoff (1932) has found a glycerin extract of the cortex (interrenalin) "effective in prolonging life and relieving symptoms in advanced Addison's disease" when given orally. Levy Simpson[2] administered Rogoff's extract by mouth to one patient and obtained "definite and considerable improvement," but he found that subsequent batches of a glycerin extract prepared by other chemists produced, when given by mouth, "trembling, shakiness, pallor, tightness across chest, nausea and vomiting"—perhaps because it contained adrenaline. With G. E. Vilvandré, he showed that ingestion of a 1/1000 solution of adrenaline will sometimes cause colicky abdominal pain associated with jejunal contractions; and there may be similar pain when dried suprarenal gland is taken by patients with Addison's disease.

Grollman and Firor have found it possible to prolong the survival of adrenalectomised rats and dogs by giving them a preparation of cortical tissue through a stomach-tube, but the dose required was five times the dose for injection, and (contrary to the experience of Britton, Flippin, and Silvette with cats) the remedy was not effective when the animal was already prostrate with adrenal insufficiency. The refined extract is at present far too expensive for use under these doubtful conditions, and efforts were accordingly made to prepare cruder products which would be equally efficacious for oral administration. Unfortunately the suprarenal gland is apt to be highly toxic when ingested, because of the breakdown of adrenaline into phenolic derivatives, and before making the extracts it was necessary to take great care that all the medulla should be dissected away from the cortex soon after slaughter of the cattle from which the glands were obtained. With this precaution the crude extracts were almost as troublesome to prepare as a refined one. The next step therefore was to explore once more the possibilities of administering glandular tissue itself. The older clinicians used whole gland in Addison's disease, and without conspicuous success; but the reason why it was ineffective therapeutically apparently is that the cortical hormone is rapidly oxidised by enzyme action after death. Grollman and Firor claim to have got over this difficulty by destroying the enzyme with heat before it can do its work. After dissection from the medulla the cortex is conveyed (frozen in alcohol) to the laboratory and there ground up and dropped into boiling water. With the "enzyme-free" concoction thus obtained a dog was successfully kept alive over a long period, and it is thought that in cases of mild adrenal insufficiency in human beings such preparations might be valuable. But Grollman and Firor admit that the great amount of material which must be ingested "precludes their use in severe cases, in which, moreover, the occurrence of gastro-intestinal symptoms would render their oral administration impossible."

The evidence as a whole suggests that some extracts of suprarenal gland are of value, in not very severe phases of Addison's disease, when given by mouth. Too much must not be expected from this form of treatment in its present state of development; but the fact (referred to by Prof. E. C. Dodds in his Goulstonian lectures[3]) that a simple chemical modification of the œstrin molecule renders it more active by mouth permits us to hope for similar progress in other departments of endocrine therapy. E. C. Kendall and co-workers[4] at the Mayo Clinic report that they have isolated an active crystalline form of the cortical hormone, and state that it is probably an α-hydroxy aldehyde.

A SEVENTEENTH CENTURY PHYSICIAN

Claver Morris was born in Dorsetshire in 1659 and died at Wells, Somerset, in 1726, so that his life of 67 years covered five reigns. His father was a country parson who had served in the Civil war on the Royalist side as a cornet of horse. Morris matriculated at New Inn Hall, Oxford, in 1675, took his B.A. in 1679, his M.B. in 1683, and M.D. in 1691. In 1683 he became an Extra Licentiate of the Royal College of Physicians. He set up in practice at Wells as a consulting physician and wrote a diary dealing with events in his life between 1685 and 1726. This diary, edited by Dr. Edmund Hobhouse, has recently been published[5]; it contains his accounts, the names of all his patients, and the fees he received. We learn, for example, that the interment of the first Mrs. Morris in 1689 cost £50, of which £14 11s. was for gloves provided for the mourners. Until he married again Morris paid a widower's tax of 26s. a year. A house that he built for himself in Wells, and began in 1699, cost £807, and is still standing (1933) and in the occupation of one of the prebendaries.

The features of chief interest in this diary are admirably epitomised and expounded in a series of introductory chapters by Dr. Edmund Hobhouse, who brings to the task expert knowledge both medical and antiquarian. The reader is able to form an excellent idea of the kind of man Morris was, and of the conditions under which he lived. He occupied a good social position, did not operate or attend confinements, and seems to have occupied himself chiefly in writing prescriptions. He possessed a laboratory in his house and was evidently an expert pharmacist who spent much time in chemical experiment. The fees charged by him were strictly proportioned to the status of his patients—e.g., in Wells he charged the poor half a crown, the small tradespeople five shillings, the substantial townspeople and officials half a guinea, and the gentry and clergy a guinea. Dr. Hobhouse remarks that as the value of money then was four or five times that of to-day these fees were high. On the other hand, Morris's fees for country visits appear low—e.g., two guineas for a journey of 17 miles, and only 12 guineas for a visit that took him away for nearly a week. After the first three years his total earnings were £200–£300 a year, so that Dr. Hobhouse thinks that for the last 15 years of his life Morris made the equivalent of over £1000 a year. As his three wives were all possessed of money, and Morris was an excellent business man, he became well to do, acquired a lot of land around Wells, and was on close terms of friendship with many of the county families.

[5] The Diary of a West Country Physician A.D. 1684–1726. Edited by Edmund Hobhouse, M.D. London: Simpkin Marshall Ltd. 1934. Pp. 155. 5s.

Perhaps wisely, considering the state of medical knowledge at the time, Morris rarely mentions his patients' ailments; but his efforts to relieve them by bleeding, purging, clysters, sweating, or emetics are recorded. When these failed he had little else to offer. He was very fond of music and was the mainstay of a local musical society; in his will he expressed a wish that "A Consort of Musick of three Sonatas at least" should be performed in the room where his body was placed before it was carried out for interment. The impression derived from a study of his diary is that Morris lived a useful and prosperous life and deserved well of his fellow men, with whom he was obviously popular. He was buried in the cathedral, and, according to the fashion of the times, a highly eulogistic epitaph, in Latin, was inscribed on his monument in the cloisters of Wells.

HEAT REGULATION IN THE TREATMENT OF GANGRENE

Two American physicians, Dr. I. Starr[1] and Dr. E. L. Sevringhaus,[2] have been treating gangrene of the lower limbs in a foot cradle constructed to maintain a constant temperature as nearly as possible that of the blood. Starr argues that wherever the essential lesion is in the peripheral vessels it is as important that the temperature should not rise too high as that the limb should be protected against cold: an excessively hot environment may produce cyanosis as surely as will exposure to cold, for the vascular disease prevents the increase of circulation that should accompany the increased metabolism of higher temperatures. The increased demand for oxygen is not satisfied, and pain, which has been relieved by a lesser degree of heat, returns as the cyanosis reappears.

The cradle, of which Dr. Starr has designed one pattern and Dr. Sevringhaus another, is equipped with a bimetallic thermoregulator, and the heat is supplied, as in the more usual type of bed cradle, by incandescent lamps. Reliance is placed on convection for the distribution of heat throughout the cradle, and the inaccuracy thus introduced is not more than 2–3° if the cradle is covered by the blankets. Starr has found some advantage in supplying oxygen to the limb for absorption through the skin. By a special modification of the cradle, cradle and limb are enclosed in a rubber bag, with all wiring and contact points outside the bag to avoid fire. The percentage of oxygen in contact with the leg is maintained at 60–80 by a fresh supply introduced three or four times daily; accumulation of moisture is circumvented by the introduction of copper wire trays holding calcium chloride, and wet gangrene is thus prevented. The cradle designed by Sevringhaus is a modification of Starr's, but on a considerably larger scale. It is a small chamber, covering all the lower part of the bed, and the feet and lower parts of the legs can lie in it without undue confinement, being visible through windows at the side; they are carefully separated from possible contact with hot and rough objects by means of baffles. Both authors are enthusiastic about the value of the constant temperature in the treatment of gangrene; it relieves pain and it promotes healing. Starr quotes five cases in which limbs were saved after amputation was thought to be inevitable on the observation of competent surgeons. Desiccation by the use of calcium chloride, may, he says, convert a wet into a dry gangrene and so prevent infection of the necrotic area.

A MEMORIAL TO DR. HAIG FERGUSON

It is not given to many men to hold the place the late Dr. Haig Ferguson won for himself by the force of his personality. Skill in his own particular department of medicine earned the respect and honour of the whole medical profession in Edinburgh and far beyond. Less well known was the extent to which, as a wise and far-seeing philanthropist, he influenced and helped many hundreds of needy girls at a critical period of their lives. For over 40 years he identified himself with the fortunes and work of the Lauriston Home where both prenatal and postnatal care are provided for unmarried mothers and a refuge afforded to those who are often in the extreme of misery. This home, which is lineally descended from the St. Luke's Home, founded by Halliday Croom, has a somewhat precarious existence, being entirely dependent upon the slender payments of the inmates, along with such subscriptions as a rather restricted circle of friends contribute. These, being mainly due to the personal influence of Dr. Haig Ferguson, will now tend to cease. An appeal is now being made by an influential committee, of which Prof. R. W. Johnstone is chairman, for a sum of £5000 which would place the work on a lasting and permanent basis and perpetuate the memory of a great and good man.

Donations for the "Haig Ferguson Memorial Home" may be sent to Mr. R. H. Wallace Williamson, C.A., 37, Melville-street, Edinburgh.

THE ISOLATED KUPFFER CELL

By the employment of a most ingenious device Peyton Rous and J. W. Beard[1] have been able to isolate and study the Kupffer cells of the liver in the rabbit and dog. The animal receives a series of intravenous injections of gamma ferric oxide a part of which is taken up and stored in the Kupffer cells. The liver is washed out with tyrode solution under low pressure. When the washings become clear of blood the pressure is raised and the Kupffer cells are loosened and washed out by alternately distending the liver with fluid and gently massaging the organ while the fluid is released. The Kupffer cells are next drawn out of suspension by causing the fluid to flow in a thin layer through a glass chamber under and around a long glass tube the outside of which is coated with a collodion membrane, while the inside contains a rod of soft iron. A giant eye magnet is fixed vertically beneath this chamber and, on passing a current, the iron rod in the tube becomes secondarily magnetised and the Kupffer cells collect on the collodion membrane.

The isolated cells were studied both by the supravital technique and by tissue culture in plasma and in serum. They appeared in supravital preparations as spherical or ovoid cells of about 30 to 40 μ though forms engorged with many particles might be as large as 100 μ. They flatten out on a glass surface and extrude a characteristic large circular membrane of clear cytoplasm which maintains a slow but constant motion compared by the authors with the flow of lava. They segregate neutral red promptly and in all respects are typical clasmatocytes but with certain morphological features that serve to differentiate them from clasmatocytes obtained from other organs of the body. The cells are extraordinarily sticky and cling to anything with which they come into contact. The stickiness of leucocytes, according to the authors, is negligible by comparison. They are also very sensitive to injury and withstand changes in temperature and pH only poorly. In tissue culture very little special activity was observed until the cells were brought into contact with a layer of lens paper. This seems to have stimulated them by providing a kind of window-ladder, and it was found that the healthy cells climbed from the floor of the dish in which they were placed on to the paper and spaced themselves at almost regular intervals along the surface of the fibres. They moved slowly along the fibres and tended to wrap themselves round those that were narrow, assuming a spindle form. It was rarely found that cytoplasmic processes of the cells extended between adjacent fibres, and this suggests that histologists are wrong in visualising the Kupffer cell as a cell that plants itself athwart the blood stream in the liver sinuses, attached by a few tentacles only to the adjoining wall. It is much more likely that the cell lies firmly like a slug along the wall. This view is supported by the observation that it is impossible to dislodge the Kupffer cells of the normal liver in appreciable numbers by forcible perfusion.

ENDOMETRIOSIS

ENDOMETRIOSIS is the name given to the condition in which endometrial tissue, in the form of nodular or diffuse tumour-like masses, is found in abnormal situations. The tumours have no capsule, and though benign in structure, and usually in behaviour, may infiltrate surrounding tissues in clinically malignant fashion. Whether metastasis ever takes place is still uncertain. The ectopic endometrium undergoes decidual and menstrual changes, and these can be detected in superficial tumours, which increase in size and become tender at the menstrual period.

A distinction is generally made between internal and external endometriosis. It is called internal when endometrial tissue invades the wall of the uterus or Fallopian tube; it is external when it involves the external surface of the uterus or tube, the ovary, rectovaginal space, bladder, or intestine, or when it occurs extraperitoneally, in the groin, at the umbilicus, in laparotomy scars, in the vagina or perineum. The clinical features naturally vary with the location of the disease. Those of the genital type have lately been well described by H. Heidler.[1] The obstinate character of the dysmenorrhœa and menorrhagia—the chief symptoms—and their failure to respond to medical measures, diathermy and curettage are shown to be an important differential sign. Two of the rarer sites—the bladder and the scar of a laparotomy wound—are dealt with respectively by R. B. Phillips [2] and H. F. Harbitz.[3] Phillips has collected 29 cases of vesical endometriosis, including one of his own. Frequency and dysuria are the earliest symptoms, and are often cyclical; hæmaturia occurs later. The only means of differential diagnosis is by cystoscopy, and if necessary biopsy. Harbitz's monograph deals with external endometriosis in general, and especially with the form developing in scars. He desribes 17 cases of his own, and reviews 176 others. The condition is usually a sequel to operations upon the uterus or adnexa, especially such as involve opening the uterine cavity (subtotal hysterectomy, Cæsarean section); but in 15 cases it followed appendicectomy. Hysterotomy in early pregnancy seems especially liable to result in endometriosis of the scar; indeed, of Harbitz's 17 cases 14 followed this operation. He considers at length the various theories of the causation of external endometriosis, and concludes that implantation following the escape of viable particles of endometrium—whether by direct extension through the wall of the uterus or tube, or by retrograde menstruation, operation, or in other ways—suffices to explain all cases.

INTRAVENOUS ALCOHOL FOR ACUTE BARBITURISM

IN a recent communication[1] to the French Academy of Medicine, Prof. Carrière, Dr. C. Huriez, and Dr. P. Willoquet, of Lille, gave an account of their clinical observations and animal experiments with alcohol as an antidote to the barbituric group of drugs. The case which first suggested this treatment to them was that of a woman of 23, who swallowed 5·0 g. of veronal and then 100 c.cm. of 95 per cent. alcohol to make sure. Instead of being comatose for at least 24 hours as she would have been had she taken this dose of veronal by itself, she slept only for five hours and recovered without more ado. Shortly after observing this case, the authors of this communication read an account by Dr. Le Loupp of a patient, a man aged 38, who irrigated an overdose of gardenal with cider, port, and brandy, drinking five or six glasses of the latter. In this case also the recovery of the patient seemed to be due to the conflicting action of the gardenal and the alcohol. It may be recalled in passing that injections of somnifene are beneficial in delirium tremens. The animal experiments consisted of injecting barbiturates into rabbits subsequently given intravenous injections of alcohol. The results were confirmatory of the clinical observations. Accordingly, on April 13th last, the first therapeutic attempt to exploit these observations was made on a woman, aged 22, brought to hospital in a state of slight coma. It transpired that she had taken 1·50 g. of gardenal. She was given an intravenous injection of 30 per cent. alcohol 20 c.cm. once an hour, and on the fourth injection she awoke to complete consciousness. The dosage in this case was known to be safe, for from 30 to 50 c.cm. of 30 per cent. alcohol have been given by intravenous injection with impunity for pulmonary suppuration. Though the optimum dosage remains to be determined, it is probable that at least 30 c.cm. of 30 per cent. alcohol should be given every hour till the patient awakes, the intravenous route being chosen to gain time.

EFFECT OF EXTREMELY HIGH ALTITUDE ON MUCOUS MEMBRANES

IN order to study the effects of residence at a very high altitude on the upper respiratory tract, a study which he believes has not previously been made, Dr. Ernesto Raffo, of Lima, travelled to Casapalca, a mining centre in the Andes of Peru situated at a height of 13,621 feet above sea-level, where the barometric pressure is only 19 inches of mercury.

---

[1] Wien. klin. Woch., April 13th, 1934, p. 467.
[2] Jour. Obst. and Gyn. Brit. Emp., April, 1934, p. 165.
[3] Acta Chir. Scandinavica, 1934, vol. lxxiv., supp. xxx.

[1] Bull. de l'acad. de méd., 1934, No. 18.

He made observations[1] on residents already acclimatised, and on members of his party who had recently arrived from sea-level; the latter, however, could not be investigated thoroughly, as they all suffered from mountain sickness. In the majority of the inhabitants examined, the nasal mucous membrane was of a deep red colour, sometimes with a crusting secretion, and there was dilatation of the capillaries of the nasal system over Kiesselbach's area, which explained the liability to epistaxis; the soft palate was wine-red in colour, interspersed with little violet spots; there was a slight œdema and congestion of the uvula, and the vessels on the posterior pharyngeal wall were dilated. The hard palate was also congested, but to a less degree, as indeed was the whole of the buccal mucous membrane. Similar alterations were to be seen in the larynx, where the vocal cords were congested and streaked with vessels; a hoarse voice is common in these regions. Retraction of the drum was observed and, very constantly, hyperæmia of the membrane with dilatation of the vessels along the malleus. Chronic middle-ear and tubal catarrh, with deafness of the conduction type, is very frequent; such lesions are more marked in those with nasal obstruction or sinusitis, which are also of very common occurrence. In 14 natives he examined the sensitivity of the labyrinth by the caloric and rotary tests, and found it increased in nine cases. A similar, but slighter, hyperæmia of the mucous membranes was found in the people who had accompanied Dr. Raffo from Lima; no difference in acuity of hearing was detected, but the excitability of the labyrinth was increased. All these alterations are no doubt fairly to be attributed to the reduced atmospheric pressure and the extreme dryness of the air at this immense altitude. It does not follow that a moderate elevation has any harmful effect upon the mucous membranes.

PRIMARY CÆCOSTOMY IN APPENDICITIS

ILEUS, whether paralytic or due to post-operative adhesions, is the most dreaded of all complications of acute appendicitis. E. R. Easton and W. J. Watson[2] believe that its occurrence can be predicted at the time of appendicectomy, and that by deliberate institution of a fæcal fistula a fatal issue can be prevented. The death-rate from appendicitis is causing much concern in the United States at the present time: the deaths per 100,000 of the population in 1929 had risen to the figure of 15·2, as compared with 11·8 in 1919. While recognising that the use of purgatives by the patient in the early stages of stomach-ache, and delay in operating, are two definite factors contributing to the high mortality from this disease, Easton and Watson have concerned themselves chiefly with improvement of operative technique. They believe that in the exercise of correct judgment in dealing, at the time of operation, with associated complications, there lies great hope of obtaining a successful outcome in even the worst type of case. Removal of the appendix is not all that is asked of the surgeon, and especially is this true where the appendix is either perforated or gangrenous, and where the condition is complicated by abscess-formation or by diffuse peritonitis. In an attempt to determine the factors that might assist recovery from complications Easton and Watson were struck by the fact that in a series of 100 complicated cases, 18 had fæcal fistula, either deliberately produced by operation or arising spontaneously, and that of these 18 patients only 1 died, though there were 12 deaths in the complete series of 100. The cases in which they advise primary cæcostomy or enterostomy are those in which the gut is distended, with a dull lustreless peritoneal coat and adhesions between the coils. Where the peritonitis is diffuse, they recommend that the opening should be at least a foot above the ileocæcal junction; in the more common condition, in which there is plastic peritonitis, or abscess-formation around the terminal ileum and the cæcum, they advise cæcostomy. They use Wagenstein's technique for enterostomy, a number 14 (French) catheter draining the bowel. Cæcostomy they perform through a stab-wound lateral to the main abdominal incision; here a number 20 (French) catheter is inserted, and after passing through the ileocæcal valve is guided into the ileum. A series of purse-string sutures hold it into position in the cæcum, and the latter is held to each end of the peritoneal wound by a catgut stitch.

The institution of intestinal drainage is said to forestall the onset of paralytic ileus, and, by preventing distension of the bowel by gas and fluid, to preserve its normal motion, and to avoid the formation of obstructive adhesions. As a rule no special difficulty is to be anticipated from the fistula. Most cases are said to heal spontaneously; about one in seven will require an operation for closure. Easton and Watson believe that a primary drainage of the bowel is so much more likely to be life-saving than a secondary drainage after the onset of symptoms of ileus, that its performance should be considered in every complicated case of appendicitis.

KING EDWARD'S FUND

THE Prince of Wales presided at the annual meeting of King Edward's Hospital Fund for London on Tuesday, when he announced that the Fund had again maintained its distribution at £300,000 entirely out of annual income. For the seventh year in succession the voluntary hospitals of London had shown a credit balance of income over expenditure, the balance for 1933 being the largest of the seven. The increase of income was no doubt partly due to exceptionally large legacies but other voluntary income was keeping very steady. Payment from patients continued to increase, either direct or through contributory schemes like the Hospital Saving Association which in 1932 paid the London hospitals £340,000. The King's Fund, said the Prince, was gradually coming to exercise some of the functions of a kind of central body for the voluntary hospitals of London, using its influence while respecting their individuality and their freedom. The activities of the Fund's propaganda committee included a fresh series of mock trials and the miniature hospital which was now touring in the north of England, and other schemes were in preparation. The parliamentary committee was promoting a general Bill authorising hospitals to provide pay beds for patients of moderate means. They had been told, he said, that the stream of voluntary gifts was drying up; recent gifts for building schemes suggested a kind of drying up which might well excite the envy of the Metropolitan Water Board.

THE third Macewen memorial lecture of the University of Glasgow will be given by Prof. René Leriche, of the University of Lyons, on Tuesday, June 19th, at 4.15 P.M. Prof. Leriche will speak on experimental and clinical researches on angina pectoris and its surgical treatment. The lecture is open to past and present students of medicine and to others interested.

THE PREVENTIVE ASPECTS OF MEDICINE

A Series of Lectures in progress at King's College Hospital Medical School

XXV.—PUBLIC AGENCIES WHICH EXIST FOR THE PREVENTION OF DISEASE

THE public agencies which exist for the prevention of disease are now so numerous that little beyond their bare recital will be possible within the compass of a single lecture. It will be convenient to group them under 11 headings:

1. Those dealing with environmental hygiene and the purity of air, food, and water.
2. Control of the acute infectious diseases.
3. The medical supervision of expectant, parturient, and nursing mothers, and of infants and school-children.
4. Organised national schemes for the control of tuberculosis and venereal diseases.
5. The control of industrial diseases.
6. The National Health Insurance scheme.
7. General hospital provision and poor-law domiciliary medical relief.
8. Mental ill-health.
9. The prevention of blindness.
10. Medical research.
11. Education of the public in matters affecting health.

Environmental Hygiene and Purity of Air, Food, and Water

Although the efforts of medical officers of health up to the beginning of this century were largely occupied in a struggle to improve environmental hygiene, yet a knowledge of the principles involved had been known from early times. The tragedy of the industrial revolution in this country was that urban communities were allowed to develop without any thought as to the penalty which would surely have to be paid later on for their failure to plan and control their areas and provide the amenities requisite for health.

As an indication of early knowledge on these matters, the Mosaic Law indicated that the ground used for dwellings must be free from accumulations of filth.

The elaborate arrangements made by the Romans for a supply of water to their cities are well known. Nineveh, which was a city centuries before Rome was, had a drainage system. Agrigentum, Athens, and Rome are all known to have had public drains. In the twenty-second Book of the Odyssey Homer describes the burning of sulphur by Ulysses, a process for purifying environment still carried out by sanitary authorities. Unpleasant smells were associated with outbreaks of disease—as indeed they still are—and so long ago as 1283, the City of London passed an ordinance to control the melting of tallow.

I would refer those who are interested in the early history of public health to Sir John Simon's classic book, "English Sanitary Institutions."

Responsibility for ensuring a healthy environment is now placed on the local sanitary authorities. These are the county boroughs—large towns which are independent of the county administration and which exercise within their areas all local government functions, including administration of the laws relating to public health, education, poor-law, highways, and, outside the metropolitan area, control of the police. They are responsible direct to the Ministry of Health and the other government departments concerned. With a few exceptions, such as Canterbury, they contain populations in excess of 50,000, and in the case of Birmingham the population exceeds a million.

Other sanitary authorities are the City of London, municipal and metropolitan boroughs, and urban and rural district councils.

All these sanitary authorities must appoint a medical officer of health and a sanitary inspector whose duties are set out in an order of the Ministry of Health. They have many executive functions and they advise their councils on matters within their province. The first of the duties of a medical officer of health is "to inform himself as far as practicable respecting all influences affecting or threatening to affect injuriously the public health within the district." He must also inspect his district to keep himself informed of the conditions injurious to health existing therein.

In what may be called large-scale operations, the county councils function in all areas other than those of the county boroughs. They must appoint a county medical officer of health. In certain parts of the country there are combinations of authorities for specified purposes, or ad-hoc bodies have been set up—e.g., for water-supply through the agency of water boards, for sewerage and disposal of sewage by drainage boards. There are also river pollution prevention boards, regional town planning boards, asylums and joint hospital boards, and so forth. If an analysis is made of the functions of local authorities it will be found that most of them have some relationship to the health of the community.

A brief summary of these functions with respect to this subsection of my paper is as follows:—

Securing an adequate supply of pure water for each household.

The making and enforcement of building by-laws to secure sufficiency of air space around a house, its sound construction, prevention of rising damp, &c.

The making and enforcement of drainage by-laws.

The construction of sewers and the disposal of sewage.

Provision for the collection and disposal of refuse.

The abatement of nuisances.

The prevention of nuisance from smoke.

The control by licensing and inspection of common and seamen's lodging-houses, of houses-let-in-lodgings, and offensive trades.

Administration of the Housing Acts, including the power to build new houses, the duty to abolish slums and rehouse those dispossessed, and to require the repair of houses where this is necessary.

The inspection of food prepared or sold in the district with power to seize and condemn unsound food and prosecute the vendor.

The taking of samples of food and drink for analysis by the public analyst, and prosecution of those selling food not of the nature, substance, and quality demanded.

The inspection and licensing of dairies, cowsheds, and milk-shops, and of bakehouses.

They also have power, and in some cases the duty, to provide public mortuaries, burial grounds, crematoria, parks and open spaces, baths and wash-houses, and so forth. Appointments of registrars of births and deaths must also be made. They also administer the law concerning canal boats, tents and vans, and other unusual places used for human habitation, and are responsible for town planning.

Speaking generally, these duties are carried out with considerable efficiency and much of the recent decline in the national death-rate may be ascribed to the enormous improvement in the environmental conditions under which urban dwellers live as a result of the activities of the local sanitary authorities.

Control of the Acute Infectious Diseases

Much of the work of the pioneers of public health was devoted to the control of the spread of the acute infectious diseases. The cholera outbreaks in this country of 1832, 1849, 1854, and 1866 profoundly stirred public opinion and were a direct cause of our early sanitary legislation. To-day this control of the acute infections may be discussed from two angles, first, the prevention of the introduction of disease from abroad, and, secondly, the steps taken to control the endemic acute infections.

With regard to the first, the original method was that of quarantine; the personnel of a vessel coming from an infected port was inspected, and if a case of plague, cholera, or yellow fever were discovered, the vessel was sent to a special mooring place and detained there for a considerable period. This was not only very costly for the shipowner but did not in fact prevent the spread of the disease, as illicit communication with the shore was very difficult to control.

More enlightened methods are now in use. Various international conventions have been held in order to secure uniformity of practice throughout the maritime nations of the world. The local agencies in this country for enforcing the law are the port sanitary authorities, each with its own medical officer of health. In most countries the port sanitary service is national and not local as in England and Wales, but the Ministry of Health keep close watch over this branch of public health and the national exchequer pays half the cost.

A vessel coming from a foreign port sends a wireless message to the port sanitary authority if there is any suspected infectious disease on board or any circumstances require the attention of the port medical officer of health; the message states the ports from which she has come and whether or not there have been, or are, cases of sickness on board. The customs officers also question the master of the vessel as soon as they board her, and in vessels without wireless, or if the sending of a message has been neglected, this may be the first intimation that there are cases of sickness on board. In cases where there is any reason to suspect the presence of infectious disease the port medical officer boards the vessel and examines all passengers and members of the crew before anyone is allowed to go ashore.

If a case of a serious infectious disease is found, the patient is removed to hospital and the passengers are not allowed to leave until they have supplied particulars of the addresses to which they are going. This information is then sent forthwith to the medical officer of health of the district to which the passenger is proceeding, and it is his duty to keep the person under surveillance, which for this purpose means daily inspection, until all risk of his contracting the infection has passed. During recent years the most common disease for which this procedure has been invoked is small-pox, and not infrequently long lists of small-pox contacts have been received in London, for distribution throughout the country, of passengers for England disembarked at Marseilles. Similarly, Plymouth, the Port of London, Liverpool, and Glasgow often despatch long lists to various parts of the country. If the crew is being paid off a similar procedure takes place.

One of the greatest trials of a port medical officer is when it is reported to him that dead rats have been found in, for example, a grain ship from the River Plate, or one which has come from India and the Far East. When this happens, all unloading of the cargo must cease, the rats must be examined for plague, and if this is found, a complete fumigation of the vessel with hydrogen cyanide must take place. Any passengers must be traced and put under surveillance, the crew must be kept under close observation, and every possible step taken to prevent rats from getting ashore. To lessen the risk of rats conveying plague from country to country, periodical disinfestation is now required or the production of a certificate—valid for six months—to the effect that the rats are so few that exemption from deratisation may be given.

The increasing use of aeroplanes as a means of rapid transport from country to country has added another risk of the introduction of serious epidemic diseases from abroad, and an international convention has recently considered the matter and made recommendations as to the most suitable methods of dealing with this menace. Speaking quite generally, the recommendations as to examination on entry to the country and surveillance of contacts follow the same lines as those successfully adopted for dealing with ships.

A function of port sanitary authorities which may be mentioned is the medical inspection of aliens. This is not primarily designed to detect cases of infection or contagion, though, in the early days, cases of trachoma in transmigrants were not infrequently seen, but to ensure that no alien is allowed to enter the country who is likely to become a charge, through illness, on public funds.

Akin to the above-mentioned methods for preventing the introduction of human diseases are those administered through the Ministry of Agriculture to prevent the introduction of diseases of animals which sometimes affect man. Rabies has now disappeared in this country, but it would almost certainly reappear if dogs from abroad were allowed free access. All such dogs must spend some months in quarantine before they are allowed to proceed beyond the port of disembarkation. The illegal introduction of dogs from abroad by aeroplane has been attempted, and firm steps have had to be taken to prevent this. As a result of the occurrence of cases of psittacosis, an order has been issued controlling the importation of parrots.

The control of indigenous infectious disease is a matter which concerns all sanitary authorities, and this occupies much of the time of local health officers.

We must first consider what steps are taken to immunise individuals against infectious disease. The vaccination laws date from 1840. We still pay lip service to compulsory vaccination of infants, but where the parents conscientiously object, exemption is readily obtainable and at the present moment less than 50 per cent. of the infants of the country are vaccinated at the public expense by the public vaccinators and those exempted exceed those vaccinated. In fact, the position is so ludicrous that many are now of opinion that we should give up all pretence of requiring compulsory vaccination by statute and simply provide free vaccination for those who would like it.

Local sanitary authorities have power to provide facilities for Schick testing and immunisation against diphtheria, and many are developing this side of their work though public apathy is great and progress is slow.

In chronological order, the first great step taken by public authorities for the purpose of controlling the acute infections, after the provision of facilities for vaccination, was the provision of fever hospitals, most of which date from 40 to 50 years ago. The reason was because at that time scarlet fever was very prevalent and had a very high case-mortality rate. It was thought that the isolation of the patients in hospital would soon bring an epidemic to an end. Unfortunately, experience and a better knowledge of epidemiological laws have shown that that was a vain hope. Most of the susceptible intimate family contacts have already been infected before the patient is removed from home, and for this reason and owing to the existence of missed mild cases the prevalence of scarlet fever has been but little affected by the provision of isolation hospitals. These hospitals are, however, of great value in the treatment of serious cases of the acute infectious diseases. Fortunately, scarlet fever is now of a much milder type than it was a generation ago, though even in this disease severe complications can be prevented by efficient hospital treatment. Cases of diphtheria and typhoid fever are admitted to isolation hospitals and in many areas measles and whooping-cough also.

In fact, many think that where fever hospital beds are limited, complicated cases of measles and uncomplicated cases from unsuitable homes should have a prior claim to admission over uncomplicated cases of scarlet fever.

It is the duty of the medical officer of health of a sanitary authority to take such measures for the prevention of any infectious disease as he is legally authorised to take under any statute in force in the district or by any resolution of his council. In order that he may do this, he must know where the cases of "fever" are, and this he does by means of the "notifications" which he receives from the doctor in attendance (incidentally notification is also required from the head of the household, though in practice it is always left to the doctor). Compulsory notification, under penalty, of certain acute infectious diseases has been statutory since 1899. There is a procedure by which diseases may be added to the list. For example, chicken-pox is often added during the prevalence of small-pox. Measles and whooping-cough are not compulsorily notifiable in most districts, though a few have added them to the list either in respect of every case or of the first case in a family.

Certain diseases are compulsorily notifiable throughout the country under orders made by the Minister of Health. Examples are puerperal pyrexia, acute primary pneumonia, and malaria. A full list of diseases compulsorily notifiable in any district may be obtained on application to the local medical officer of health, who will also supply the necessary forms.

On receipt of a notification the medical officer of health, or more often a sanitary inspector or health visitor, visits the house and completes an inquiry form from which it is desired to learn :—

(1) The date of onset of the disease;

(2) The source of the infection;

(3) The persons with whom the patient has been in contact since he became infectious; and

(4) The steps taken to prevent the spread of the infection.

These forms are studied by the medical officer of health and the necessary action taken thereon. It may be that a "missed" case will be discovered, that the milk-supply or shell-fish are under suspicion, that better arrangements for home isolation are desirable, and so forth.

We are, however, in a changing world with regard to the control of a disease like scarlet fever. The value of removal to hospital is being questioned, as is also that of terminal disinfection. Fumigation by sulphur dioxide or formaldehyde was a universal requirement 20 years ago, but in some areas it is being discontinued. Again, it was thought at one time that the desquamating skin of scarlet fever cases was infectious and the patients were detained in hospital until all desquamation was completed—sometimes for eight or nine weeks and nearly always for six. It has been found by experience that the desquamating skin is not infectious and that it is safe to discharge an uncomplicated case on the twenty-eighth day. Serum treatment is now largely used in fever hospitals for preventing complications and shortening the period of treatment.

I must mention three more points before leaving the acute infectious diseases :—

(1) Diphtheria antitoxin may be supplied free by the local sanitary authority for use by private practitioners.

(2) Most authorities make arrangements under which free facilities are provided for obtaining bacteriological reports on specimens sent by private practitioners such, for example, as reports on throat swabs, on cerebro-spinal fluid, on blood-serum for agglutination tests, and so forth.

(3) A sanitary authority does or can do little to control one of the most serious of the acute infectious diseases—namely, influenza. Influenza itself is not compulsorily notifiable, though acute influenzal pneumonia is. The action of the sanitary authority in times of epidemic consists mainly of endeavouring to secure as much hospital accommodation as possible, and of advising the public of the dangers at such times of frequenting places which are crowded and ill-ventilated. Those who have developed the disease are counselled to remain at home in bed until the risk of spreading the infection has passed, and thus, incidentally, protecting themselves against the risk of serious complications.

W. ALLEN DALEY, M.D., M.R.C.P., D.P.H.
Principal Medical Officer, Public Health Department,
London County Council.[1]

(To be concluded)

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. H. L. P. Peregrine to *Victory*, for R.N.B.

Surg.-Lts. H. E. B. Curjel and H. de B. Kempthorne to *Pembroke*, for R.N.B.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. A. E. B. Jones, having attained the age for retirement, is placed on retd. pay.

Maj. S. J. Barry to be Lt.-Col.

The undermentioned Lts. on prob. are confirmed in their rank: G. L. McLeod and C. B. R. Pollock.

Lt. P. V. O'Reilly resigns his commn.

ARMY DENTAL CORPS

Lt.-Col. A. R. Inglis retires, receiving a gratuity.

Maj. D. Clewer to be Lt.-Col.

Capt. J. W. Vasey to be Maj.

ROYAL AIR FORCE

Flight Lt. A. A. Townsend is promoted to the rank of Squadron Leader.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: T. C. Macdonald and J. S. Carslaw.

DEPUTY DIRECTOR-GENERAL, A.M.S.

The War Office announces that Col. W. P. MacArthur, D.S.O., F.R.C.P.I., hon. physician to the King, who is at present consulting physician to the Army and professor of tropical medicine at the Royal Army Medical College, has been appointed deputy director-general, Army Medical Services, with effect from Sept. 16th, 1934, in succession to Col. F. D. G. Howell, D.S.O., hon. surgeon to the King, who, on completion of his temporary tenure of the appointment, will proceed to India to take up the appointment of deputy director of medical services at Army Headquarters which will become vacant on Dec. 26th next. Col. MacArthur will be succeeded by Lt.-Col. J. Heatly-Spencer, R.A.M.C.

THE LEISHMAN PRIZE

Maj. F. McKibbin, Royal Army Medical Corps, has been awarded the Leishman Prize for the year 1933, consisting of a silver medal and a sum of £30 for his work in the interests of military hygiene.

The Leishman Prize (Officers) is awarded annually for the best piece of work in any branch of Medicine, Surgery, or the allied sciences, or in connexion with the general duties of the Royal Army Medical Corps, by an officer of the Royal Army Medical Corps, or Army Dental Corps, or by an officer removed from either of these Corps but still on the Active list.

NORTH PERSIAN FORCES MEMORIAL MEDAL

Surg. Lieut.-Com. S. G. Rainsford, Royal Navy, has been awarded the North Persian Forces Memorial Medal for the year 1933, for his paper on Laboratory Methods of Diagnosis of Brucella Infections, published in the *Journal* of the Royal Naval Medical Service, January, 1933.

The North Persian Forces Memorial Medal is awarded annually for the best paper on Tropical Medicine or Hygiene published in any Journal during the preceding twelve months by a Medical Officer, of under twelve years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service, provided the Memorial Committee consider that any of the papers published has attained a standard of merit justifying an award.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL

SUMMER SESSION, MAY 29TH–JUNE 2ND, 1934

Penal Cases

A DIVORCE DECREE

The Case of Laurence Handley Ashken, registered as of 28, Hillside-drive, Edgware, Middlesex, L.M.S.S.A. Lond. 1927, who had been summoned to appear before the Council on the following charge :—

> "(1) That being a registered medical practitioner you frequently committed adultery between September, 1931, and January, 1933, with Stolzie May Ferris, a married woman, whom you were attending professionally, of which adultery you were found guilty by the decree of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated February 12th, 1934, in the case of Ferris *v.* Ferris and Ashken, in which you were the co-respondent. (2) That by reason of the said facts you abused your position as a registered medical practitioner. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Francis Spaul Ferris.

Dr. Ashken appeared in answer to his notice and was accompanied by Mr. Victor Williams, counsel, instructed by Messrs. G. and A. Cosens, solicitors.

Mr. Harper, opening the case, said that he could not understand on what respondent relied for his defence, as both adultery and professional relationship were admitted.

Mr. Ferris, the complainant, gave evidence showing that the acquaintance between his wife and respondent had arisen out of professional relationship. They had all three become very friendly. His wife had confessed to adultery one Sunday morning, and Dr. and Mrs. Ashken had been summoned to the house for a discussion. Respondent had flatly denied the charge at first, he had declared that it was possible for a woman in her condition to imagine such an event, and suggested that she had had intercourse with other men and was imagining that it was respondent. Complainant had told him to leave the house, and had subsequently had his wife examined by another doctor who had found her of sound mind. He had therefore asked his wife to leave the house and had instituted divorce proceedings. A little later Dr. Ashken had rung up his office and the line had been tapped and the conversation recorded. Dr. Ashken had said he wished to confess, and had later called at the office in a very distressed condition and confessed and asked forgiveness. He had eventually consented to make a written statement. (An official from the Divorce Court produced the statement and Mr. Ferris identified it.) Later respondent had met him at North Wembley station and asked if he might make a public apology in the press, but complainant had refused and had obtained a decree nisi. Dr. Ashken had broken up his home. Cross-examined by Mr. Williams, he said that his wife's moral character had been entirely satisfactory until she met respondent. He did not deny that Dr. Ashken had twice suggested he should give up the case, but denied that he had given it up or that they had ever sent for another doctor before Dr. Ashken. He agreed he had divided the blame equally between respondent and Mrs. Ferris.

Dr. Ashken, giving evidence, said that Mrs. Ferris had come to his consulting room in August, 1931, complaining of severe vaginal discharge. Friendship had developed. He had several times suggested that another doctor should take over the case, while the friendship continued, but Mr. Ferris had always refused. Adultery had been committed four times only. He bitterly repented what he had done and was much ashamed of himself.

In answer to the Legal Assessor, he admitted that he had denied adultery at the first interview.

Mrs. E. A. Ashken described two telephone conversations which she had overheard between Mrs. Ferris and her husband ; in both, Mrs. Ferris had said that Mr. Ferris would not take proceedings if she (Mrs. Ashken) would leave her husband, but she had not done so.

Sister Margaret Bethan described Mrs. Ferris's nervous condition and her infatuation with Dr. Ashken. She had nursed three or four hundred cases for respondent and his conduct had always been most professional. Miss Kathleen Sell, formerly a nurse, described Dr. Ashken's treatment of about two hundred cases in a local nursing-home as quite unobjectionable. Mrs. Ferris had been very unsatisfactory as a patient, often refusing treatment and then telephoning for the doctor to return at once. The vicar of Kenton and several patients testified to Dr. Ashken's high character and reputation and their trust in him. Dr. Arthur Whitesides, who had been Dr. Ashken's assistant for six months, declared that his conduct had been above reproach in every way, and amplified his opinion under cross-examination. Dr. J. Sakula gave evidence that he had also been assistant to Dr. Ashken and had attended Mrs. Ferris, finding her very difficult and troublesome. Dr. Samuel Halperin, formerly Dr. Whiteside's assistant, testified to the high reputation of Dr. Ashken among former patients. Mr. Williams also put in a number of statutory declarations as to character from medical men, and addressed the Council, arguing that his client had been tempted and tried beyond human endurance.

Mr. Harper addressed the Council, deploring the fact that so many responsible persons—witnesses and those sending statutory declarations—should attempt to minimise the gravity of adultery, which was admitted.

After deliberation in camera the President announced that the Registrar had been directed to erase from the Register the name of Laurence Handley Ashken.

ALLEGED ADVERTISING

The Case of James Stansfield Collier, registered as of 30, Wimpole-street, London, W.1., M.R.C.S. Eng. 1894, L.R.C.P. Lond. 1894, who had been summoned to appear before the Council on the following charge :—

> "(1) That being a registered medical practitioner you authorised and/or acquiesced in the publication in the *Observer* of Jan. 7th, 1934, of an account of an interview with you headed 'Sleeplessness : Drugs which prevent it : Safety and Danger.' (2) That you thereby advertised for the purpose of obtaining patients with a view to promoting your own professional advantage. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Maximilian Fourman.

Dr. Collier was accompanied by Mr. Oswald Hempson, solicitor, on behalf of the Medical Defence Union.

Mr. Fourman read his statutory declaration in the witness-box. He said he was a Russian advocate who had married a British woman and had been employed in insurance offices here. His son was physically and mentally defective and they had consulted Dr. Collier and found him unsatisfactory. The article in the *Observer* had made them think that respondent was a scientific man who knew about drugs. But for that article they would never have wasted their time consulting such a man. The next victim might be some poor English working-man who would not dare to express disapproval of a name followed by so many letters. Complainant also read the letter he had written to Dr. Collier, describing his child's case in great detail, before the consultation. At the request of the President, he then read out the article from the *Observer*.

The Registrar read Dr. Collier's reply to the letter, admitting the interview and its publication but maintaining that nothing in the article could be regarded as advertising. Mr. Fourman's son had proved to be a mentally defective epileptic who was being quite properly treated by his doctor with luminal.

Mr. Fourman addressed the Council, saying that he played the part of the man who called the fire-brigade when he saw a fire. He thought his duty would have been fulfilled by drawing the Registrar's attention to the article, and had not anticipated having to take part in proceedings. He contrasted Dr. Collier's treatment of him with the code of conduct instilled into members of the Russian Bar. He had been treated most hospitably in England and hoped Dr. Collier would not be too severely punished. Anything the Council could find in respondent's favour would cause complainant great happiness.

Mr. Hempson called Dr. Collier as a witness and Dr. Collier explained the circumstances under which the article had been written. He had granted an interview because he thought the public was getting a wrong impression of the danger of certain drugs. They were being much discussed in the lay press and many of his patients distrusted them and refused to take them, so that his treatment was handicapped. He had gone carefully over the journalist's written account of the interview and had given permission for his name to be used. The article correctly represented the interview as far as the inverted commas went. He had not authorised any setting forth of his own capacities. A proof had been submitted and called for but he had no recollection of seeing or correcting it. Mr. Fourman's account of the consultation was substantially correct; he had examined and prescribed for the boy and taken fairly full notes. He had told complainant that he should have written beforehand if he knew he could only afford one guinea. He had had one other patient as a result of the article—a hopeless drug addict—and had taken no fee, nor had he received any fee from the *Observer*. There was emphatically no idea of attracting patients; he was not in financial need of patients and had as much work as he could do. He admitted unwisdom in letting this article go through without proper scrutiny.

The Legal Assessor pointed out the opening paragraphs, not in inverted commas, and Dr. Collier said those had been added and had not been in any script seen by him. (They referred to him as a noted specialist.)

Mr. Hempson read a statutory declaration from the representative of the *Observer*, confirming Dr. Collier's account of the interview and its reasons. The maid had handed him back the draft article in its original envelope, unaltered and unsigned, saying that Dr. Collier had been unexpectedly called away. He took full responsibility for the opening paragraphs which he had added without Dr. Collier's knowledge. Mr. Hempson argued that there was no "criminal intent" in the matter. Nobody who knew respondent would think it possible that this article would be to his advantage.

After deliberation in camera the President announced that the Council had found the first charge proved, but not the second. Dr. Collier had allowed publication of an unwise article which had inevitably laid him open to these proceedings, but the Council accepted his assurances as to motive, and left the matter there.

CHARGES OF CANVASSING

The Case of Malcolm Herbert Cecil Dyson, registered as of Lyemun, St. Mawes, Cornwall, M.R.C.S. Eng. 1926, L.R.C.P. Lond. 1926, B.S. 1927, M.D. 1929, U.Lond., who had been summoned to appear before the Council on the following charge:—

> "That being a registered medical practitioner you have canvassed personally and/or by means of an agent the patients of David Morrison with a view to inducing such patients to become patients of yours, and in particular: (1) In or about the months of November, 1933, and February, 1934, you canvassed William Francis Butland; (2) in or about the month of February, 1934, you canvassed Henry Hooper; (3) in or about the early part of February, 1934, you canvassed William Henry May; (4) in or about the month of February, 1934, you canvassed James Sara. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. David Morrison, M.B. 1894, U.Lond. Dr. Dyson was accompanied by Mr. Oswald Hempson, solicitor, for the Medical Defence Union.

Dr. Morrison opened his case, complaining of most unfriendly treatment from respondent who had, he alleged, tried to drive him out of the place and carried on the most outrageous canvassing of complainant's patients. Complainant had brought four statutory declarations but had only been able to bring two witnesses from St. Mawes. He submitted that Dr. Dyson's letter to the Registrar amounted to a confession and revealed motive, and the intention to wreck his small practice and make it unsaleable in the fear that a young, energetic man might buy it and offer the respondent serious opposition. He read his letter offering to stop proceedings if respondent would make amends and described an effort on the part of the vicar to negotiate. He read out correspondence with the local nursing association dealing with his assertion that a nurse had told a patient that respondent was "the" doctor of the association.

Dr. Morrison entered the witness-box and was cross-examined by Mr. Hempson. He said he had first gone to St. Mawes in May, 1932, as locum tenens for the deceased Dr. Murray and had carried on the practice for three months. Some days after leaving he had returned and set up in practice for himself. He had offered to purchase the practice, which was producing about £300–£350 a year. His present practice was about the same size, but that did not mean that he had secured practically the whole of that practice. He did not suggest that respondent was unfriendly during his *locum* period. He had set up in practice there because Dr. Dyson and his partner had, for a year before Dr. Murray's death, been scheming to spoil the practice of a dying man, so that the practice for which Dr. Murray had paid £1200 was only bringing in about £300 at the time of his death. Dr. Dyson and his partner had eventually bought the practice, after complainant had told them he had no intention of setting up in practice there. He admitted having received a letter from the British Medical Bureau saying that for him to set up in practice at St. Mawes would not only be contrary to medical etiquette, but also in contravention of the terms of their introduction of him as locum. He thought Miss Murray had played him a dirty trick in selling the practice to Dr. Scott and Dr. Dyson after asking him to make an offer, although he agreed his offer was a very poor one and he had not expected it to be accepted. He denied that there had been a meeting of doctors in Falmouth about his advertising methods and that the profession there had refused to recognise him. He admitted that his letter to respondent demanded amends or compensation as an alternative to these proceedings, and that the proceedings were punishment of Dr. Dyson.

The Legal Assessor asked what complainant would say in answer to the defence that Dr. Dyson had been seeking to protect his own patients rather than attract complainant's. Dr. Morrison replied that his action in starting practice at St. Mawes might have been unconventional, but he was free to set up where he liked. He agreed that he had started practice a month after Dr. Dyson and his partner had bought the practice of Dr. Murray.

Sir Henry Brackenbury asked if complainant had seen the four people named in the charge while he had been a locum. Dr. Morrison replied that they had all been Dr. Murray's patients; he could not be sure whether he had attended them or not.

William Francis Butland gave evidence that Dr. Dyson had twice approached him, asked why he was not on his (respondent's) panel, and said that Dr. Morrison had no business there. Witness had said he had no wish nor reason to change. In reply to Mr. Hempson, he said that they had shaken hands at the end and been quite friendly.

William Henry May gave evidence that Dr. Dyson had told him he ought not to be on Dr. Morrison's panel, that Dr. Morrison had no business there and would have to go, and that witness should transfer to respondent's list. Respondent had had to ask his name, not knowing him personally.

Dr. Morrison put in two statutory declarations from aged patients too ill to travel, describing similar attempts to canvass.

Dr. Dyson, giving evidence on his own behalf, said that he had looked after Dr. Murray's patients gratuitously during his illness and that he had been offered the lighthouse appointment after his death and had refused it until Dr. Murray's affairs should be settled up. As a result of the usual letter sent round by the Panel Committee after he had bought the practice, some 160 out of 315 patients had transferred to him. The panel was the most important part of Dr. Murray's practice. He admitted having seen the four patients mentioned in the charge and had spoken to them because he had made a point of telling all these people the truth. He had never attempted to persuade anybody to join his panel. There had been a strong rumour in St. Just that Dr. Morrison had bought Dr. Murray's practice, and he and Miss Murray had gone round to tell the facts. They had proposed to send round a circular letter on this point. He and his partner, Dr. Scott, had bought the practice, and the first notification they had had of Dr. Morrison's return was a letter to Dr. Scott. They had offered him the practice at the price they had paid for it, but he had refused. They had appealed to the British Medical Association and the Panel Committee, but neither had been able to help. Dr. Morrison had soon tried to sell his practice and respondent had advised an applicant to see the British Medical Association before buying it.

Cross-examined, he said that after his predecessor's death there had been an interval during which Dr. Murray had been the only doctor in St. Mawes. His only object in going round was to tell the truth, and no patients had transferred to his panel in consequence. He had taken every possible step to prevent complainant selling his nucleus.

In reply to the Legal Assessor, he agreed that he knew in November, 1932, that some 150 of Dr. Murray's former panel patients had not transferred to his panel on Dr. Murray's death and presumably did not want to. He admitted that he had been in error in not approaching these patients until November, 1933, 12 months or more after they had changed to Dr. Morrison. It was only gradually, however, that he realised that the people of the district thought Dr. Morrison had bought Dr. Murray's practice. Frankly, he had taken the law into his own hands at that stage.

Dr. F. S. Scott, Dr. Dyson's partner, said that a branch of his practice had been established in St. Mawes in 1925, before Dr. Murray had gone there, and there had been continuity of that practice ever since. Dr. Murray had introduced opposition. He had himself asked Dr. Murray's executors to put in a locum so that there might be no suggestion that they wanted to get the work for themselves. He had offered Dr. Morrison the practice at the price they had given for it and promised not to interfere with him. Until quite recently there had been a persistent belief that Dr. Morrison had bought it. Dr. Dyson and he had acted together, advisedly, as they could see no other way of righting a wrong. He had wanted to prevent Dr. Morrison from selling something he had never bought. From the first he had regarded it as their practice and not as Dr. Morrison's.

After Mr. Hempson had addressed the Council, and it had deliberated in camera, the President announced that the case was dismissed, the facts not having been proved to the satisfaction of the Council.

The Case of William Samuel Dixon, registered as of The Surgery, Fifth-street, Horden, Co. Durham, M.B., B.Ch. 1923, U.Dub., who had been summoned to appear before the Council on the following charge :—

> "That being a registered medical practitioner you have systematically canvassed during the months of February and March, 1934, in and around the district of Horden in the County of Durham, by means of an agent or agents, the patients of Dr. A. M. Wilson, Dr. G. C. Henry, and Dr. William Martin, with a view to inducing such patients to become patients of yours, and in particuler: (1) On or about Feb. 27th, 1934, you canvassed John Henry Burnham, a patient of the said Dr. A. M. Wilson; (2) on two occasions in or about the month of March, 1934, you canvassed Henry Kaye and his wife Mrs. Emma Kaye, patients of the said Dr. A. M. Wilson; (3) at the end of February or the beginning of March, 1934, you canvassed Mrs. Ethel May Rudd, a patient of the said Dr. G. C. Henry: (4) on or about March 3rd, 1934, you canvassed Kitty Tatters, a patient of the said Dr. William Martin. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainants were the London and Counties Medical Protection Society, who were represented by Mr. T. Carthew, counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors. Dr. Dixon appeared in answer to his Notice and was accompanied by Mr. Oswald Hempson, solicitor, for the Medical Defence Union.

Mr. Carthew explained that respondent and Dr. Wilson had been partners from 1925–1934, but negotiations for continuation had failed and the partnership had ended by effluxion of time. Respondent had set up in practice alone. All four doctors had similar practices, consisting of four types of patient: (1) panel; (2) colliery club (the families of insured men), the money being paid by the colliery; (3) private club patients; and (4) private patients. After a while the three doctors had become aware of a wholesale door-to-door canvassing campaign carried on by respondent. They had written to him about it, and he had replied that it was the only way to find out which were in fact his patients, and that the club patients had to be notified of the dissolution of partnership; he said that he had consulted a solicitor and members of the ethical and panel committee before acting, and the visitation was one of inquiry and notification only and not of canvassing. Mr. Carthew could prove, he thought, that the colliery could have been asked to supply a list of the patients of the partnership, and a circular could then have been sent to them, to fulfil the articles of partnership which required notification of dissolution to all patients. The fact was that practically every house in Horden had been visited. Dr. Wilson had had no part in or knowledge of this proceeding. It was not yet possible to tell the effect on the panel patients, but the colliery club figures showed that the former partnership had had 1390 patients, of whom 1183 had transferred to Dr. Dixon. The private club had had some 250 members, of whom only 28 had remained with Dr. Wilson.

Dr. A. M. Wilson said that he had been in practice in Horden since 1915, that respondent had come to him as assistant in 1923 and had been his partner from 1925–1934. He had known nothing of any canvassing plan. He had from time to time obtained lists of the club patients from the cashier of the colliery, and produced specimen lists. There would be no difficulty, so far as he knew, in Dr. Dixon getting a list if he had gone the right way about it. A notice of dissolution of partnership had been displayed in the surgery. He confirmed the transfer figures. Cross-examined by Mr. Hempson, he agreed that Dr. Dixon had been doing the bulk of the work of the partnership, and might be expected to get more patients than himself on its dissolution. In the absence of addresses it would be impossible to trace the patients from a list of names. He had not complained to the local ethical committee. He had sent his collector round from house to house after the dissolution to find out which patients were staying with him. He did not recall speaking to the dispenser about Dr. Dixon. Re-examined, he said he had not put much activity into the work since the death of his wife two years before the dissolution, but he had worked every day, walking his rounds. His collector had not visited at every door but only a given list of addresses.

In reply to the Legal Assessor, he said he had never applied to the colliery for a list of patients and been refused.

Dr. G. C. Henry said he had obtained lists of patients from the colliery without delay or difficulty. He produced the books, corrected by the colliery clerks. Dr. Dixon was a very active opponent. He himself had set up in practice in Horden a few months after his brother had ceased to be assistant to Dr Wilson, who had later complained to the Central Ethical Committee about witness. Dr. Dixon had been anxious to give evidence against him in that case and had later complained of witness's criticism of him to a patient. He had brought an action against Dr. Dixon and been awarded £50 damages. The panel committee had inquired into the canvassing charge and had decided that there was no case to go to the Ministry; the visits had been indiscreet if not irregular, but no attempts had been made to influence patients. Miss Wearmouth was his servant. He had prepared a statement for Kitty Tatters to sign, but it had never been signed. He admitted that Dr. Martin's partner had complained to the Ethical Committee that witness had canvassed.

Dr. W. Martin also testified to having applied for particulars from the colliery and having obtained them with ease. Cross-examined, he said that the list was a joint one between himself and partner; they received a joint cheque and the colliery had no knowledge of which patient belonged to which doctor. After the war he and Dr. Wilson had been the only doctors in the district and the lists had got rather mixed up; witness described the way the doctors had managed to sort them out. He had not employed a Mr. Edward Malone to go round visiting and inquiring.

In reply to the Legal Assessor, he said that he and his partner divided their patients into two districts, each taking one, subject to choice by the patient. A list from the colliery would be a practice list, but each partner could tell roughly which patients preferred him; the great majority did not mind which they saw. The list could not be accurately divided into two. In reply to Dr. Bone, he said the junior partner could get the list just as easily as the senior. In reply to Sir Henry Brackenbury, he said the lists supplied were fairly accurate, but not so inaccurate as to necessitate a house-to-house visitation to ascertain the patients.

Mr. Henry Kaye testified that he had been asked by Mr. Carruthers to change from Dr. Wilson to Dr. Dixon; he and his wife had refused. Cross-examined, he agreed he knew Mr. Carruthers well; on the second occasion Mrs. Herbert had also been present. He had no grudge against Dr. Dixon.

Mrs. Kaye confirmed her husband's evidence.

Mrs. E. M. Rudd also declared she had been asked to change doctors.

Mr. Carthew read a statutory declaration from a witness not present and asked leave to call a number of witnesses who had not made statutory declarations. Mr. Hempson objected, as he had had no proof of the evidence. The Legal Assessor advised the Council not to accept this evidence.

Miss L. I. Wearmouth, a domestic servant in the service of Dr. Henry, described a visit of the collector to her friend, Kitty Tatters, in her presence, Kitty Tatters being on Dr. Martin's panel. She had told Dr. Henry and signed a statement. Kitty Tatters next day had wanted to destroy the statement, as all her family were on Dr. Dixon's panel.

Dr. Dixon, examined by Mr. Hempson, said that he had started with a one-third share, increased to one-half, and under the new agreement was to have two-thirds and an assistant. He had had a very large practice and panel list. For the last four or five years he had done three-fourths and for two years five-sixths of the work. In the last year he had done all the night work and 130 confinements to Dr. Wilson's two; he had taken three hours morning and evening at the surgery where his partner had taken half an hour. The negotiations had only broken down because he had wanted the assistant to come with a view to partnership and Dr. Wilson would not agree. Very few of the patients would see a notice hung in the surgery. He had seen the clerk to the Durham Insurance Committee, who had arranged to circularise the panel patients. The private collector at his last visit to private club patients had been instructed to inform them. He had visited the colliery manager, Mr. Best, and tried to get the change-over of the colliery club patients made at the colliery office, as had been done in another case but without success. He himself had never seen a list, and if Dr. Wilson had ever received a list it was without respondent's knowledge. He had had no list himself and had seen no way of getting one but sending visitors round. He had told them to call at all the colliery houses. (About 95 per cent. of the population lived in colliery houses, council houses, and scheme houses, and were constantly changing their homes.) He had told them to ask first of all if the inhabitants were patients of Drs. Wilson and Dixon, and if the answer was No they were to leave at once. If Yes, they were to ask which doctor the patient would choose on dissolution of the partnership. They were told not to say which doctor they represented until the patient had made his choice. If the patient chose Dr. Wilson they were to pass on, as the money at the colliery was already deducted in Dr. Wilson's name. On no account were they to interfere with panel cards. Nothing was done after March 6th, as the Medical Defence Union had advised him on that day that the procedure was undesirable. His visitors had collected 510 pit notes out of the 1380 pit patients on the joint list. On the list he had received from the colliery there were names and no addresses; he had telephoned and been told that no other information was ever given. He could not ascertain all the addresses from that list. He had had no idea of attracting patients to himself; he already had more than he could deal with. He had not, to his knowledge, taken the patients of any other doctor. Relations between members of the profession in Horden had been strained ever since he had been there.

Cross-examined by Mr. Carthew, he said that Dr. Wilson had refused to discuss with him at all how he should notify the patients. It had never occurred to him that his agents might exceed his instructions and he had heard his patients say the method had been adopted before. In reply to the Legal Assessor, he said he had not consulted Dr. Wilson about the list as the partnership had by then been dissolved. In reply to Dr. Bone, he agreed that the colliery club patients were dependents of miners who were panel patients and whose addresses ought to have been found on the panel cards. The visitors had not brought back any panel cards. In reply to the President, he said that about 40 per cent. of the circulars sent out by the panel committee had been returned "not found in the village," owing to the frequent changes of address, and many patients had confessed to having received the circulars and not understood them.

Mr. E. Best, manager of the colliery, described Dr. Dixon's visit to him. The patients of Drs. Wilson and Dixon were all under the name of Dr. Wilson. Dr. Dixon had asked witnesses to let the workmen inform the office which doctor they wanted; witness had refused lest the colliery be accused of influence. A list of names without addresses had been furnished to Dr. Dixon. It was the custom to supply the doctors with names and addresses, but Dr. Dixon had been told that the work of searching for the addresses would take the office staff about a month. About 75 per cent. of the houses belonged to the company, which could move the people about so that large families had large houses, and they were being moved about all the time. If the doctors sent in their own lists the colliery would keep them up to date, but this partnership had not followed that practice. It was not the custom of the coalfields generally to supply addresses.

Mr. V. Williams, one of the visitors, testified that Dr. Dixon's instructions had been as Dr. Dixon had stated and that they had been expressly forbidden to use any influence or persuasion. He had visited between March 2nd and 6th only. He had been given an area to visit and had done nearly the whole of it, except that in a number of houses he had found no one at home. He had had nothing to do with panel cards and had never tried to persuade people to come to Dr. Dixon. He described his visit to the Tatters's, declaring that Mrs. Tatters's daughter had mentioned the panel cards and he had refused to have anything to do with them. He had not asked her if she would like to be on Dr. Dixon's panel. Cross-examined by Mr. Carthew, he said he had been a club collector for many years, paid by commission. He knew many people in Horden pretty well, but had not stopped to chat at the houses. He had carried out his work conscientiously and without bias. In reply to the Legal Assessor, he said he had not called at any house if he knew the inhabitants were patients of other doctors; those had been his instructions. He had given in his reports each night. He had not been paid for the work.

Re-examined, he explained that his commission was on private club patients only, not colliery club patients.

Mr. C. Knox, another visitor, gave similar evidence, as did Mr. R. Carruthers and Mr. F. Glaister, who said in cross-examination that they had acted without payment out of gratitude to Dr. Dixon.

Mrs. Mary Ann Finlay testified that Mr. Carruthers had called at Mr. Kaye's house but had seen only Mrs. Kaye. He had merely asked her with which of the two doctors she intended to continue.

Miss Katherine Tatters corroborated Mr. Williams's evidence, and said that Miss Wearmouth had asked her to sign a statement which was false in every respect, especially in that it said that Mr. Williams had offered to make it easy for her to change over to Dr. Dixon's panel.

Mr. Hempson summarised several more statutory declarations corroborating the earlier evidence. In addressing the Council, he admitted that Dr. Dixon had done a most unwise thing in sending collectors to all the houses in the district, but not a heinous thing, for they had only been told to inform partnership private patients of the dissolution and ask to which of the partners they wished to adhere. He put in statutory declarations to character and a petition signed by a large number of the inhabitants of the district.

After deliberation in camera the President announced that the facts had been proved to the satisfaction of the Council, but judgment had been postponed until May, 1935, when respondent would be required to attend and to produce evidence of his conduct in the interval.

ALLEGED MISCONDUCT

The Case of Mortimer McGhee Russell, registered as of Sideways, Higher Green, Ewell, Surrey, M.B., B.Ch. 1916, M.D. 1920, U.Dub., who had been summoned to appear before the Council on the following charge:—

"(1) That being a registered medical practitioner you committed adultery with Violet Rosetta Smith, a married woman, who and whose family you had attended professionally, of which adultery you were found guilty by decrees of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, both dated Jan. 29th, 1934, in the case of Russell v. Russell, in which you were the

> respondent, and in the case of Smith v. Smith and Russell, in which you were the co-respondent. (2) That by reason of the said facts you abused your position as a registered medical practitioner. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

There was no complainant in this case.

Dr. Russell was accompanied by Mr. Herbert Malone, counsel, instructed by Messrs. Lawrance, Messer and Co., solicitors. Mr. Harper said that the facts under (1) were admitted, but (2) was denied on the ground that professional relationship had ceased in August, 1931, and the association leading to adultery had not started until May, 1933. He put in the decree and the shorthand notes from the Divorce Court, pointing out that Mrs. Russell had complained in 1931 and been assured there was nothing but friendship between respondent and Mrs. Smith, and that her husband had left her in 1932.

Mr. Malone set out the facts chronologically. Respondent had graduated in 1915, entered the R.A.M.C., and married in 1923. Almost from the beginning both Dr. and Mrs. Russell had realised that it was a very unfortunate mating. Mrs. Russell was so consumed with jealousy that neither man nor woman could be entertained socially in their house without a quarrel. Mrs. Smith had been a patient of the partnership and respondent had seen her three or four times a year. In November, 1930, she had had appendicitis and been operated on by Dr. Dainty, assisted by Dr. Russell. At that time she had been merely a rather troublesome patient. In 1931 she had been attended by Dr. Russell for miscarriage, July 6th–24th, and he had never attended her again. Respondent had gone to her husband, told him that Mrs. Smith was getting no benefit from his treatment as she would not obey him, and recommended another doctor, who had then taken over her case. She had disliked that doctor, and in October Dr. Dainty had communicated in the ordinary professional way with respondent saying that Mrs. Smith wished to become his patient, which she remained to this day. Respondent had tried to arrange a separation, but his wife had said "divorce or nothing." On his wife's suggestion in 1932 he had picked up a woman in order to give cause for divorce, and a petition had been filed in October, 1932, and come into the list in January, 1933, but before its hearing Dr. Russell decided to persuade his wife to try again. They had done so, but had again failed and separated. He had met Mrs. Smith by accident in December, 1933, not having seen her since July, 1931. She had then told him for the first time that she was unhappy and they had exchanged confidences. Some months later she had telephoned him and they had become friendly. He had made another unsuccessful attempt to become reconciled with his wife after that. Respondent proposed to marry Mrs. Smith as soon as the divorce decree was made absolute. He had not practised at all for 12 months.

Dr. Russell confirmed his counsel's account of the facts. Cross-examined, he admitted meeting Mrs. Smith and her husband casually in the street several times between 1931 and 1933. In 1932 Mrs. Russell had been complaining about everything under the sun, and had objected to his alleged intimacy with a dozen women, including Mrs. Smith. He had probably said there was nothing in it, but had not said there was friendship. In reply to the Legal Assessor, he said he had left Sutton in October, 1932, and Mrs. Smith had continued to live there. After that time he had not seen nor communicated with Mrs. Smith.

Dr. R. Dainty also confirmed the facts as set out by Mr. Malone. In October, 1931, Mrs. Smith had come to him asking if he would take her on as a patient and he had been attending her ever since. He had left Sutton in September, 1933, but she had continued to visit him. Counsel's description of Mrs. Russell had been quite an accurate one.

The President announced, after deliberation, that the facts alleged had not been proved to the satisfaction of the Council.

(To be continued)

NOTES FROM INDIA

(FROM A CORRESPONDENT)

BIOCHEMICAL TESTS IN CIRRHOSIS OF THE LIVER

A BIOCHEMICAL investigation of the blood in 53 patients admitted to the King George Hospital, Vizagapatam, South India, for cirrhosis of liver has recently been carried out by Dr. M. V. Radhakrishna Rao in the pathological department of the medical college to which the hospital is attached.[1] He found the fasting blood-sugar to be low in most of the cases of hepatic cirrhosis, the average being 78·24 mg. per cent., whereas the average fasting blood-sugar of normal Indians is 117·0 mg. per cent. He attributes the low blood-sugar to an impairment of the "glycogenetic and glycogenolytic functions" of the liver. No symptoms of hypoglycæmia, however, have been observed, even though in some cases the blood-sugar is less than 60·0 mg. per cent. The blood-urea in these cases was mostly within normal limits or rather higher, and only rarely fell to a low level; Dr. Rao takes this to indicate that the "ureogenetic function" of the liver is not usually deranged—even in advanced stages of hepatic cirrhosis. The non-protein nitrogen and the creatinine are also within normal limits or on the high side. The plasma cholesterol was low in most of the cases, but it is not certain whether this is due to the destruction of the hepatic parenchyma or to the diet of the patients, which was poor in cholesterol and fats.

DR. RANGACHARI

The death occurred in Madras on April 24th of Dr. S. Rangachari. Dr. Rangachari, who was born in 1882, joined the Madras Medical Service in 1905 after a brilliant college career. He worked at various hospitals before he became a district medical and sanitary officer in 1914–15. He then became interested in obstetrics and gynæcology and was made assistant superintendent of the Government Maternity Hospital, Madras, in 1919, a post which he held in addition to that of surgeon of the General Hospital, Madras. In 1926 he retired from Government service and started a private nursing-home with well paid assistants and an adequate nursing staff in the Southern Presidency, where he did valuable work in the training of post-graduates who were allowed access to the patients in the capacity of assistants. Dr. Rangachari had exceptional surgical skill and clinical judgment, and his loss as a teacher will be widely felt.

TYPES OF MENINGOCOCCI IN CALCUTTA EPIDEMICS

Dr. A. K. Sen and his collaborators in Calcutta have published (Jour. Indian Med. Assoc., March, 1934, p. 288) a preliminary report on the bacteriology of the epidemic of cerebro-spinal fever which occurred in Calcutta at the end of last year. Altogether 42 different strains of meningococcus were isolated, of which 35 were typed by agglutination tests with the standard type sera. They found that during the period when these investigations were in progress the epidemic strains belonged mostly to type I., type III., or "type I. or III." of the Gordon-Murray types; not one of the 35 strains belonged to type II., type IV., or "type II. or IV." These results differ from those obtained by B. Sen in Calcutta in the epidemic of March and April, 1932; he incriminated mainly type IV., and found some strains of type II. It is possible that the virulent strains are different in different epidemics, but it is also noteworthy that the strains in 1932 were collected at the height of the epidemic, and that in 1933 they were collected when the epidemic had subsided.

FAR EASTERN ASSOCIATION OF TROPICAL MEDICINE

The ninth congress of this association will be held in Nanking, China, on Oct. 1st–7th, 1934. This association is an international organisation of medical, surgical, dental, and veterinary professional men interested in research and in the prevention of tropical diseases in the Far East. The seventh congress was held in Calcutta, and the eighth in 1930 in Bangkok. Among the vice-presidents of the congress are Major-General J. D. Graham, I.M.S., representing the Government of India; Lieut.-Colonel J. Morison, I.M.S. (Assam); Lieut.-Colonel A. D. Stewart, I.M.S. (Bengal); Lieut.-Colonel F. P. Mackie, I.M.S. (Bombay); Colonel C. A. Gill (Burma); Sir Frank Connor (Madras); and Lieut.-Col. H. H. Nutt (United Provinces), and official delegates from many parts of India are expected to attend the congress.

OBITUARY

MORGAN IGNATIUS FINUCANE, L.R.C.P., M.R.C.S.

We regret to announce the death of Dr. Morgan Finucane, which occurred on May 31st at his country house, Seddlescombe, Sussex.

Morgan Ignatius Finucane was born in the Island of Ascension in 1865, the son of Dr. Daniel Finucane, an Inspector-General R.N. He was educated at the Royal Naval School, New Cross, and received his professional training at the medical schools of University College and St. Thomas's Hospital. He commenced practice in the Colonial Service, and was in succession medical officer to the Fiji Islands, medical superintendent of the Suva Hospital, and surgeon to the Victoria Hospital, Bathurst. In both colonies he acted as a stipendary magistrate, and in both, especially in Fiji, he studied the diseases of the country and their incidence upon the inhabitants, and published articles on yaws and elephantiasis from his personal observations. After 12 years with the Colonial Office he served in South Africa during the war, became civil surgeon to the R.A.M.C. at Aldershot and at the Tower of London, and also one of the medical officers to the Western Dispensary, Rochester-row. He was now appointed poor-law medical officer to the city of Westminster and did admirable work here as official, as doctor, and as philanthropist. He was for 27 years in charge of the workhouse and casualty wards, earning a high reputation for his keenness and sympathy, and becoming through his experiences with the unfortunate a reforming radical in politics.

He was called to the Bar at the Middle Temple and later acquired considerable practice as a consultant in medico-legal work. He was elected a member of the L.C.C., and served in several important capacities—e.g., as a member of the following committees, those of general purposes, children's care, and special schools. He was a manager of the old Metropolitan Asylums Board, and in 1914 was adopted as Liberal candidate for Westminster, but later joined the Labour party. He served on the Home Office Committee on delinquents and on the Lord Chancellor's Advisory Committee for the appointment of magistrates for the County of London, and has left his mark as an untiring worker both in social and political directions.

FRANKLIN JOHN LIVINGSTONE, M.D. Toront.

Franklin John Livingstone was born in 1863 at Collingwood, Ontario, and graduated in medicine at Toronto. In 1895 he settled at Ladysmith as a medical practitioner, at the same time taking up missionary work for the Canadian Methodist Church. He was appointed district surgeon at Ingwavuma, Zululand, where he was in practice until the Boer war broke out. He was captured by the Boers, but made his escape, and for a time returned to Canada, where in 1901 he married Miss Sarah Gardiner, of Kingston, who returned with him immediately to Natal. He saw active service in the Zulu Rebellion of 1906, and was awarded the Queen's Medal. He now took up practice at Pomeroy, and, later, became district surgeon of Bulwer. In 1915 he returned to Ladysmith, and remained there for eight years, having a large native practice, and carrying on farming very successfully. In 1921 he took up his residence at Port Shepstone, where he died. Dr. Livingstone had been a noted athlete as a young man and was also a fine horseman and tennis player. He is survived by his wife, a son, and a daughter.

DR. JAMES TAYLOR

LATE PROVOST OF KEITH

Dr. James Taylor, whose death was lately announced, was well known in many public capacities. He was born in New Deer, Aberdeen, in 1860, the son of Alexander Taylor, and was educated at the Grammar School and University of Aberdeen. He graduated as M.A. in 1880, and M.B., C.M. in 1883. He proceeded to the M.D. in 1887, and at the Aberdeen Royal Infirmary held the house appointments, becoming later clinical tutor in the medical school. On entering practice at Keith he filled many positions of local importance, was medical referee to the Home Office under the Workmen's Compensation Act, medical officer for the Post Office, medical superintendent of the Memorial Hospital, and examiner for recruits for the Army. With the rank of Major R.A.M.C. (T.F.) he did considerable local service during the war, was president of the Pensions Board at Keith, received the medal of the British Red Cross Society, and was made an honorary life member of the St. John Ambulance Association. He was J.P. for the county of Banffshire, acted as Sheriff's substitute, was provost of Keith from 1913 to 1919, and was a deputy lieutenant of the county.

CORBETT HOSPITAL.—On Saturday last Lord Cobham, the president, opened extensions of the hospital at Amblecote, Worcestershire, consisting of two new wings and a nurses' home, the first stage of a scheme for the provision of a new hospital. The cost of the whole scheme, including equipment, is estimated at £105,000.

PUBLIC HEALTH

The Drought

SPEAKING last week at Swindon, Sir Hilton Young described the measures which were being taken by the Government to relieve the situation caused by the drought. He was arranging for a standing conference of the three representative bodies—the British Waterworks Association, the Institute of Water Engineers, and the Water Companies Association—to act in coöperation with the Ministry, in order to bring to bear upon remedial measures all the available knowledge and experience of the experts and of those actually responsible for water-supplies. He had also appointed a special officer of the Ministry to promote the formation of regional water committees. Applications for grants under the emergency Act made it certain that the £1,000,000 would be promptly and usefully employed and would secure a real improvement in the rural areas most in need of it. The capital value of schemes already submitted exceeded £800,000.

Mental Disease and Defect in London

At the end of 1932 there was provision in L.C.C. mental hospitals, under the Lunacy and Mental Treatment Acts, for 21,760 patients.[1] The demand for accommodation is increasing and schemes are in hand for meeting it, but it is not due to increased incidence of mental disorder (the tendency is in fact the other way) but to the accumulation of chronic patients who cannot be discharged. Only 177 of the 21,760 inmates were voluntary patients, but it is significant that at the Maudsley Hospital—which is now in its eleventh year of voluntary treatment of early cases—2070 out-patients were registered during the year, while 1109 were under treatment at the end of it. Of 672 in-patients discharged in 1932 from the Maudsley Hospital 88 are described as "recovered" and 331 as "relieved." Similar treatment is also available at three general hospitals under the public health committee. It may be expected that the number of voluntary cases will continue to increase.

Of mental defect 774 new cases were reported in 1929, 1796 in 1930, 2053 in 1931, and 1006 in 1932. This large increase, the peak of which has been passed, was more apparent than real, as it was largely due to the transfer of cases from poor-law authorities after the passing of the Local Government Act. For instance, 809 out of the 1006 reported in 1932 were in transferred mental institutions or in London mental hospitals. The increase thus represents the advance in ascertainment which unified control is gradually making possible. The total number of defectives at the end of 1932 ascertained by the L.C.C. to be dealt with under the Mental Deficiency Act represented a proportion of 3·65 per 1000 of population, less than half the proportion of defectives estimated in the Wood report. The discrepancy suggests that an undue proportion of defective children discharged from special schools are not yet being notified under the provisions of the Act. Of the 3272 defectives under statutory supervision 969 are employed, a fair proportion when it is remembered that those supervised must in the main be low-grade cases. There is little or no indication in the report of the nature of the training given at the various institutions, but that the possibilities of socialisation are not lost sight of is shown by the fact that at the end of the year 329 cases were on licence with a view to ultimate discharge, a proportion of 1 to 11 of the total number in institutions as compared with 1 to 9½ in 1931. Eleven per cent. however of the cases on licence in 1932 failed to make good.

More School Nurses

Addressing a conference of head teachers, Dr. R. H. Parry, medical officer of health for Bristol, advocated an increase in the number of school nurses. The usual plan now, except for a few specialised or residential areas, is for each nurse to have the care of a group of schools, sometimes a considerable distance apart. Dr. Parry would like to see a health nurse attached to every school and in close touch with the head teacher. The nurse is thus always on the spot ready to examine any child brought to her by the teacher; the child can then if necessary be sent home forthwith for the advice of the family doctor, or to the appropriate clinic or hospital. The nurse can decide whether or not to exclude a child from school, at least provisionally, in a way that is not possible for the teacher. Experience has shown that in certain matters the accuracy of the school nurse's opinion is remarkable; for instance, in a series of difficult ringworm cases J. Kerr found the nurse's errors to be a bare 3 per cent. In scabies her opinion is almost as good, and for the presence of nits it is practically infallible. In the exceptional schools with a nurse attached she often deals with minor accidents and ailments such as conjunctivitis, blepharitis, otorrhœa, and skin conditions. It is in conditions such as these that Dr. Parry finds home treatment so unsatisfactory. Even in the few instances where the parents seek the advice of their own doctor they seldom carry out instructions. For impetigo ointment is given with advice on the proper procedure, but the vital point, the removal of crusts, is overlooked with the result that an absence of 60 days may be due to this trivial cause. When such conditions are treated by a nurse the loss of school attendances is reduced to a few days. Another function which a whole-time nurse can perform is to see that children with orthopædic, cardiac, visual, and other disabilities are kept to the restrictions which medical authority has specified. Speaking to an audience of teachers, Dr. Parry naturally refrained from mentioning how much such supervision is needed; but the fact is that, although most teachers are helpful, there are still examples of myopes subjected to inappropriate conditions. The school nurse can maintain a high standard in the lavatories and washrooms; school meals and their conduct should not be outside her province. Dr. Parry regrets that a child is medically examined only three times in its school career, but he does not advocate more examinations "if the school nurses are increased in number and utilised to better purpose." If the nurse is to be of much use in observing the children and bringing forward all those who need further investigation she must have a more limited number of children under her charge. The gain from having a nurse to each school is so great that it is surprising that the practice is so unusual.

Birth Control Advice at Clinics

In 1931 the Ministry of Health sanctioned the establishment by local maternity and child welfare authorities of clinics for women in need of medical advice and treatment for gynæcological conditions, where advice on contraceptive methods might be given to married women in whom pregnancy would be detrimental to health. The departmental committee, reporting in 1932, considered that advice and instruction in contraceptive methods should be readily available for women suffering from organic disease such as tuberculosis, heart disease, diabetes, or chronic nephritis, in which childbearing is likely seriously to endanger life. It is admitted that there is nothing in law to prevent a local authority from rendering such a clinic available for women suffering from sickness other than gynæcological. In a circular (No. 1408) just issued the Ministry expresses agreement with the committee's view that contraceptive advice would be proper also for married women suffering from such forms of sickness, physical or mental, as are detrimental to them as mothers, if it is found medically that pregnancy would be detrimental to health. What is, or is not, medically detrimental to health is left to the professional judgment of the practitioner in charge of the clinic.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 26TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 2 (last week 4); scarlet fever, 2308; diphtheria, 977; enteric fever, 19; acute pneumonia (primary or influenzal), 954; puerperal fever, 52; puerperal pyrexia, 119; cerebro-spinal fever, 24; acute poliomyelitis, 6; acute polio-encephalitis, 1; encephalitis lethargica, 5; dysentery, 4; ophthalmia neonatorum, 71. No case of cholera, plague, or typhus fever was notified during the week.

The number of cas [illegible] Hospitals of the London County Council on [illegible] follows: Small-pox, 5 under treatment, 0 [illegible] t week 9 and 0 respectively); scarlet fev [illegible] 1689; measles, 2160 (last week 2363); [illegible]; puerperal fever, 31 mothers (plus 11 babies); encephalitis lethargica, 259; poliomyelitis, 2; "other diseases," 141. At St. Margaret's Hospital there were 15 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 52 (16) from measles, 11 (1) from scarlet fever, 29 (8) from whooping-cough, 41 (13) from diphtheria, 49 (9) from diarrhœa and enteritis under two years, and 32 (4) from influenza. The figures in parentheses are those for London itself.

Liverpool and Newcastle-on-Tyne each reported 5 fatal cases of measles, Acton [illegible] other great town more than 2. Birming [illegible] from whooping-cough; Merthyr Tydfil 3 [illegible]

The number of stillbirths notified during the week was 248 (corresponding to a rate of 41 per 1000 total births), including 35 in London.

THE BIRTHDAY HONOURS

THE list of honours conferred by the King on his 69th birthday contains the following names of members of the medical profession:—

K.C.M.G.

Ambrose Thomas Stanton, C.M.G., M.D.
Chief medical adviser, Colonial Office.

G.C.V.O.

Sir Milsom Rees, D.Sc., F.R.C.S.
Laryngologist, T.M. the King and Queen.

K.C.V.O.

Maurice Alan Cassidy, C.B., M.D.
Physician extraordinary to H.M. The King.

K.B.E.

Frederick Grant Banting, M.D., D.Sc.
Joint discoverer of insulin.

Knights Bachelor

Major Robert George Archibald, C.M.G., D.S.O., M.D., R.A.M.C.
Director, Wellcome Tropical Research Laboratories, Sudan.

Rai Bahadur U. N. Brahmachari.
Medical practitioner, Bengal.

G. H. A. Comyns Berkeley, M.D., F.R.C.P., F.R.C.S., F.C.O.G.
Director, L.C.C. Radium Centre, Hampstead.

Major-General James Drummond Graham, C.B., C.I.E.
Late public health commissioner, Government of India.

Grafton Elliot Smith, M.D., F.R.C.P., F.R.S.
Professor of anatomy, University of London.

C.B. (Military)

Major-General P. H. Henderson, D.S.O., M.B.
Director of hygiene, the War Office.

Major-General Ernest Alexander Walker, M.B., F.R.C.S., I.M.S.
Director of medical services, India.

C.B. (Civil)

Rear-Admiral Percival Thomas Nicholls, M.R.C.S.

C.I.E.

Lieut.-Colonel Harold Holmes King, M.B., B.S., I.M.S
Director, King Institute, Guindy, Madras.

Lieut.-Colonel John A. S. Phillips, L.R.C.P., L.R.C.S., D.P.H., I.M.S.
Director of public health, Bihar and Orissa.

C.V.O.

Louis F. R. Knuthsen, O.B.E., M.D.

C.B.E. (Military)

Group Captain Edward Cecil Clements, O.B.E., M.R.C.S.

C.B.E. (Civil)

John Crosthwaite Bridge, F.R.C.S., D.P.H.
Senior medical inspector of factories, Home Office.

William Henry Peacock, M.B., B.Sc.
Deputy-director, health services, British Nigeria.

O.B.E. (Military)

Colonel Walter Lister, T.D.
Late assistant director, medical services, West Riding.

O.B.E.

Harry Edward Hewitt, M.D., B.S., D.P.H.
Second medical officer, G.P.O.

George MacLean, M.B.E., M.B., Ch.B.
Sleeping sickness officer, Tanganyika.

Miss Katherine Stewart Macphail, M.B.
Surgeon and superintendent, Children's Hospital, Belgrade.

Khan Bahadur K. Abdul Rahman, M.B., D.P.H.
Director of public health, Punjab.

M.B.E. (Military)

Flight-Lieutenant Francis W. P. Dixon, M.B.

M.B.E.

Joseph A. H. André, M.R.C.S., L.R.C.P.
Superintendent, Leper Asylum, Mauritius.

Yusuf Hajjar, M.D.
Medical officer, Government Hospital, Jerusalem.

Andrew Buchanan Macdonald, M.B., Ch.B.
Working at leprosy, Nigeria.

Major Frank Hermann Otto, I.M.S.
Assistant surgeon, Port Health Staff, Bombay.

Joseph L. D. Pawan, M.B., Ch.B.
Government bacteriologist, Trinidad.

Sowani Puamau.
First native medical practitioner, Gilbert and Ellice Islands Colony.

Geoffrey Osmund Schmidt, I.M.S.
Assistant surgeon, British Consulate, Kashgar.

Kaisar-i-Hind Medal

Miss Doris Louisa Graham, M.B., B.Ch.
Medical missionary, Krishnagar, Bengal.

Miss Millicent Vere Webb, L.R.C.P.
Chief medical officer, Women's Medical Service for India.

CORRESPONDENCE

OLIGURIA AND ŒDEMA

To the Editor of THE LANCET

SIR,—During the last ten or twenty years there has been an increasing tendency to minimise the rôle of the kidney in the causation of œdema. The term "extrarenal" has been forced more and more into prominence, and the decreased colloid osmotic pressure of the blood caused by diminished plasma protein content has become the current explanation of the œdema of Bright's disease.

This explanation, for which Epstein is largely responsible, is an unsatisfactory one for several reasons, the two main ones being that it cannot account for the œdema of acute nephritis (for the plasma proteins are not diminished at that stage), and that variations in plasma protein do not precede, or correspond with, variations in the amount of the œdema or the amount of urine secreted. (McClure and others.[1]) It must be admitted that in long-standing cases of pronounced œdema in renal disease (subacute nephritis and nephrosis) the total plasma protein is almost always found to be below 5 per cent., and in my opinion there is little or no doubt that the diminished oncotic pressure will *favour* and *increase* the occurrence of œdema and oliguria. But as it is manifestly absurd to say that the œdema of acute nephritis and that of subacute nephritis are caused by two totally different mechanisms, it is necessary to look for some factors common to both conditions.

In your issue of May 26th Prof. Shaw Dunn suggests that the modern theory of renal secretion (Cushny) can be made to explain the œdema of renal disease, and that the oliguria is most probably dependent upon excessive reabsorption in the tubules from a glomerular filtrate which originally may be normal in amount. This would account for the fact that water and chlorides are retained while urea is excreted. I fully agree with this view, but arrived at it through a totally different process of reasoning[2] from a consideration of the important work of Verney[3] and Winton,[4] which Prof. Shaw Dunn does not appear to have taken into consideration. These workers, following up the experiments of Rose Bradford, have formulated the law that *the composition of the urine depends upon the rate of its secretion.* If the arterial pressure is lowered or the venous or ureteric pressure increased, the filtration pressure in the capsule is reduced, with the result that the urine is secreted more slowly, there is more opportunity for reabsorption in the tubules, and the resulting urine is concentrated and of relatively high specific gravity. If in a pair of kidneys the arterial pressure of one is reduced, and the venous or ureteric pressure of the other is increased, to such an extent that the rate of secretion of urine in both kidneys is equal, the composition of the two urines is the same (as regards chloride and urea content) though proteinuria usually occurs if the venous pressure is raised. Verney also refers to the reserve forces of the kidney, the first line of defence being the *structural reserve*, all the available nephrons being called into action at the same time; the second line being the *functional reserve*, when the intraglomerular pressure is raised (usually with a coincident rise of blood pressure) the rate of secretion is increased and the composition of the urine becomes correspondingly dilute. This latter response is what happens in chronic nephritis and all varieties of renal failure, characterised as they are by polyuria and low specific gravity.

Verney and Winton's work can thus be used to explain the type of urinary secretion existing in all kinds of renal disease, by changes in glomerular pressure, and it must be admitted that such changes in pressure are at any rate probable, if unproved. In acute nephritis, for example, the glomerular obstruction leads to slow secretion, increased reabsorption, oliguria, increased specific gravity, and œdema. Nitrogen-retention is prevented by the structural reserve except in the most severe cases. In subacute nephritis the same conditions may exist, and, in addition, the extrarenal factor of plasma protein loss will increase the œdema at this stage. In nephrosis glomerular obstruction being absent and ureteric pressure presumably unaffected, it is tempting to fall back on increased venous pressure as a possible cause of the slow secretion and consequent oliguria. This would at the same time account for the albuminuria. The extremely important evidence now added by Prof. Shaw Dunn, that the glomerular vessels in nephrosis are abnormally patent, is further proof here of the calling-out of the structural reserve, and is surely compatible with, if not even confirmatory evidence of, increased venous pressure. On the other hand, the swelling of the tubules might have an effect equivalent to raising the ureteric pressure. Subacute nephritis and nephrosis probably overlap in all their functional pathology, the one being merely the extreme form of the other. Plasmaprotein loss will be a factor in each.

In chronic nephritis, where œdema has disappeared or has been absent from the start, the functional reserve is eventually called out, the glomerular pressure rises, the urinary secretion becomes rapid, and the specific gravity falls. But this stage would not be reached until the structural reserve was used up and many nephrons were out of action. Therefore nitrogen-retention will eventually occur. A further proof that Verney's law still holds good, and that the specific gravity of the urine is now low merely because the secretion-rate is high, is seen sometimes at the end of chronic nephritis (or more often of nephro-sclerosis). Heart failure occurs, *the blood pressure falls,* the high glomerular pressure fails, the secretion of urine becomes less, *the specific gravity rises,* and œdema (of cardiac type) appears. The damaged kidney, able, perhaps, still to eliminate by the aid of its functional reserve now becomes totally inadequate and uræmia overtakes the patient before heart failure has run its full course.

Assuming then that the kidney in disease continues as far as possible to obey Verney's law of secretion, one may go so far as to say that if in nephritis, oliguria and high specific gravity exist when not required to do so by the needs of the body, then a pathological reduction of filtration pressure in the glomerulus may be assumed to have occurred, and reabsorption of fluid in excess of the body's requirements will of necessity take place. As an illustration of the possible events, the following purely hypothetical figures may be given :—

1. Normal kidney; 2/3 of total nephrons active; 50 litres of glomerular filtrate; 48½ reabsorbed = 1500 c.cm. urine.

2. Acute and subacute nephritis, and nephrosis; *all* nephrons active; still only 50 litres of filtrate (owing to reduced glomerular pressure); 49½ reabsorbed (owing to slow secretion) = 500 c.cm. (concentrated) urine. Non- or low-threshold substances would be excreted

[4] Winton, F. R.: Jour. of Physiol., 1931, lxxi., 381; 1931, lxxii., 49 and 361.

as before because the amount of filtrate is the same, but a litre of saline solution is retained.

3. Chronic nephritis, nephro-sclerosis, &c.; only half of total nephrons left; 50 litres of filtrate still produced (by high pressure, rapid secretion); only 47½ reabsorbed = 2500 c.cm. dilute urine. Still no nitrogen retention, but polyuria and thirst present.

4. Advanced chronic nephritis, &c.; only quarter of total nephrons left; 30 litres of filtrate produced; 28 reabsorbed = 2000 c.cm. dilute urine. Nitrogen-retention now present owing to reduction of total filtrate, despite polyuria.

5. Superadded heart failure. A quarter of total nephrons now only produce 15 litres of filtrate (owing to fall in pressure): 14¾ are reabsorbed = 250 c.cm. of *concentrated* urine. Uræmia rapidly terminates the illness.

Certain other facts can be considered with interest in relation to these hypotheses. For instance, the old theory that the kidney of chronic nephritis has *lost* the power to concentrate is disproved by observation of the specific gravity in a terminal case with heart failure. The question also arises: is the œdema of heart failure itself (without significant renal disease) not due to the slow renal circulation and relatively high venous pressure in the kidney, instead of to a high pressure in the general venous circulation as ordinarily accepted? The difference in distribution of renal and cardiac œdemas has always been looked upon as proof of their different origin, but would it not be fair to suppose that if renal œdema occurred in a patient with an already high general venous pressure, retained fluid would accumulate in the dependent parts where that pressure was highest? Even in long-standing cases of renal œdema the distribution comes eventually to be almost entirely in the dependent parts, and only in acute nephritis, where fluid rapidly accumulates, is the distribution practically independent of the laws of gravity. Thus the general increase of venous and capillary pressure in heart failure may come to be looked upon as a secondary factor in the production of œdema, just as in nephrosis the low plasma protein content is a secondary factor, the primary and important factor in each case being the increased reabsorption of fluid in the renal tubules owing to the slow rate of glomerular filtration.

On any theory it is difficult at present to explain the absence of œdema in most recorded cases of total anuria (latent uræmia). Even when anuria occurs in the course of acute nephritis it is not necessarily in the most *œdematous cases.* But here a distinction may possibly have to be drawn between fluid which has been reabsorbed in excess and fluid which has in effect never reached the kidney at all. In the first place the kidney has done its work, though badly, and the fluid returned to the blood stream appears to be stored up in the tissues. In the second the fluid appears to be retained in the blood as if seeking elimination. The fact that in total anuria *all* the electrolytes are retained may also be a factor of importance.

Prof. Shaw Dunn's demonstration of the extraordinary extent to which a *small loss of albumin* in the glomeruli may become concentrated on its way through the tubules again upholds the possibility of vascular changes in the glomerulus, either "stasis with slight dilatation" as he supposes, or increased venous pressure, which amounts to practically the same thing and has been shown experimentally to produce albuminuria. That the albuminuria is more likely to depend on such changes than upon the prolonged action of toxins or changes in the nature of the plasma protein is suggested by the extreme rapidity with which it may clear up in certain cases. Kerridge's [5] work, on the nature of proteinuria in nephritis, if confirmed in cases of nephrosis, will finally dispose of the theory that the plasma albumin has undergone some change which renders it foreign to the organism and is being excreted.

As Prof. Shaw Dunn truly says, "it is obviously impossible at the present time to submit completely verified facts in support of every contention," but if reasoned argument on the basis of the accepted theories of renal secretion drives one to the conclusion that in certain pathological states œdema would be expected to occur, and if one finds on clinical examination that these are the precise states in which œdema does occur, it is a welcome relief to discard such vague phrases as "metabolic disturbances" and "increased vascular permeability," neither of which conditions are known to exist in renal disease, or are capable of demonstration at the present time.

I am, Sir, yours faithfully,

Sheffield, May 30th. ROBERT PLATT.

ACUTE HÆMOLYTIC ANÆMIA

To the Editor of THE LANCET

SIR,—The case of the boy, aged 2¼ years, described by Dr. H. A. Dunlop and Dr. A. G. Sanders in your last issue (p. 1169) was almost exactly similar to that of the boy, aged 3 years, which I brought before the Royal Society of Medicine on Jan. 22nd, 1932 (*Proceedings*, vol. xxv, p. 715), under the heading, Severe Acute Hæmoglobinuria in a Boy. The hæmoglobinuria in the latter case was accompanied by fever and an acute hæmolytic type of anæmia with leucocytosis. Rapid recovery followed a blood transfusion of 200 c.cm. The erythrocyte count on Nov. 27th, 1931, just before the blood transfusion, was 1,320,000, and 14 days later (Dec. 11th) it was 4,500,000. I suggested that, as no toxic or other cause for the hæmoglobinuria had been discovered, the case might represent an extreme form of "acute hæmolytic anæmia," as described by Max Lederer in 1925 and 1930.

A more characteristic example of acute hæmolytic anæmia was the case of a boy, aged 11 years, that I brought before the Royal Society of Medicine on Oct. 9th, 1931 (*Proceedings*, vol. xxv., p. 15). The erythrocyte count, which on May 1st, 1931, was 780,000, reached 6,400,000 by August 19th. I headed my description: An Anæmic Breakdown or Crisis in a Child, not connected with definite Congenital Hæmolytic Jaundice. At that time I knew of only a single case in medical literature that resembled it, but soon afterwards I found that it was a typical example of the type of anæmia described by Lederer in America, Christiansen (Copenhagen, 1929), and Fiessinger and his colleagues (Paris, May, 1931). Later on I heard of the cases of Prof. L. Parsons and his colleagues at the Children's Hospital, Birmingham.

Both my patients have remained free from another attack. It is worth noting that the colour-index was at first 1·22 in my first case, and in my second (the hæmoglobinuric) one it likewise reached 1·2 at one blood count (not recorded in my printed description).

I am, Sir, yours faithfully,

London, W., June 4th. F. PARKES WEBER.

TREATMENT OF RODENT ULCER BY FREEZING

To the Editor of THE LANCET

SIR,—I should like to compliment Dr. Semon on his admirable paper dealing with the use of carbon-dioxide freezing in dermatological practice, and I would specially endorse his statement that where firm pressure can be exercised with the snow pencil "freezing will give results as good as radium" in early rodent ulcer. I have used this method consistently for many years and have a large volume of evidence in support of that opinion. I would, however, deprecate Dr. Semon's statement that "a minimum exposure for a rodent ulcer is one minute." I am quite sure this is unnecessarily long in many cases of the more superficial type, and my own practice is always to begin with exposures of half that period. I think also that sepsis is so rare as a result of freezing that it can be practically ignored. The explanation for this fact I cannot give, but the "vital reaction" (whatever that may mean) which Dr. Semon offers as an explanation is at any rate a convenient hypothesis.

---

[5] Kerridge, P. M. T.: THE LANCET, 1934, i., 675.

Personally, I am reluctant to use freezing in positions overlying cartilage and I should never use it in any circumstances upon the eyelid over the eyeball. The acetone mixture I have found useful in certain cases of lupus erythematosus, where the degree of freezing desired is relatively slight, and the advantage of a liquid application which can follow outlines is obvious.

The fact that in certain types of rodent-infiltration spontaneous recovery may take place, as has been demonstrated quite definitely in certain cases—for example, of the type which I have ventured to call "erythematoid benign epithelioma"—suggests, I submit, that the malignity of rodent lesions has been considerably over-estimated, both by patients and by doctors. In the flat early patches the mischief is very superficial, and superficial treatments are usually entirely adequate. Indeed I have had cases in which these superficial types have not improved under X ray or radium treatment, but have responded most satisfactorily to freezing.

I am, Sir, yours faithfully,
E. GRAHAM-LITTLE,
Physician in charge of the Skin Department, St. Mary's Hospital.
Wimpole-street, W., June 4th.

CEREBRAL HÆMORRHAGE AND BLOOD PRESSURE

To the Editor of THE LANCET

SIR,—There is a widespread belief that arterial pressures maintained at systolic levels of 200 mm. of mercury or more, with corresponding diastolic levels of 120 mm. or more, are of grave prognostic import because it is thought that the risk of cerebral hæmorrhage is thereby greatly increased. While agreeing that cerebral hæmorrhage is possible at such high levels, my own experience during the past 20 years shows that the majority of cases occurring at ages above 40 years that I have seen in consultation have run systolic arterial pressures well below 200 mm., ranging for the most part from 190 to 145 mm. No inference can be drawn about the incidence of cerebral hæmorrhage from the presence of generalised arterio-sclerosis, for post-mortem observations have repeatedly demonstrated that the state of the superficial arteries bears no relation to the state of the cerebral arteries. At the base of the brain arterial circulation is carried on through small vessels of varying calibre. These are prone to local degeneration of the intima, and in them miliary aneurysms are frequent. In generalised arterio-sclerosis the march of events is more or less gradual, in most instances sufficient time elapsing for processes of repair to preponderate over those of degeneration. Of the total number of cases of arterio-sclerosis, less than half are associated with persistently raised arterial pressures, the sclerotic process representing a reaction to damage of the vessel walls induced by various factors, the chief of which are probably endogenous or exogenous toxins.

By the time that pressures of over 200 mm. have been reached, the walls of the larger vessels have usually become capable of withstanding grades of pressure far higher than would cause cerebral hæmorrhage in small arteries locally degenerated, and the subjects of extremely high pressures not infrequently manifest capacity for full work over a period of years. On the other hand, when arterioles surrounded by soft and yielding brain substance degenerate, they tend to burst at the weakest points under pressures which may be relatively moderate. High diastolic pressures are of importance in this connexion through production of continuous strain, systolic pressures constituting an additional fluctuating load which may become of sufficient magnitude to cause a cerebral artery weakened by disease to give way.

I am, Sir, yours faithfully,
Harley-street, May 30th. J. F. HALLS DALLY.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

School Medical Services

ON May 30th, in Committee of Supply on the Civil Estimates for 1934, Mr. RAMSBOTHAM (Parliamentary Secretary to the Board of Education) said he was well aware that there was an impression in many quarters that the physical condition of the children was deteriorating in consequence of prolonged economic distress.

NUTRITION IN DEPRESSED AREAS

The reports which he had received from up and down the country certainly did not confirm it.

According to the report of the school medical officer for the North Riding of Yorkshire, dated February, 1934—an area which had suffered a great deal from industrial distress —out of 13,000 children medically examined only seven were really bad cases, and the children pronounced subnormally nourished declined from 6·54 per 1000 in 1930 to 3·97 in 1933. The school medical officer wrote: "Malnutrition. the sequence of absolute lack of food, was not established. On the other hand, and as so often reported, the real cause appeared to be improper feeding; there was a sufficiency of food of a kind, but of the wrong type; there is also the malnourished child from the home of the well-to-do, a condition often associated with physical ill-health."

The school medical officer for Thornaby and Eston wrote: "There has been great depression throughout my area. About 50 per cent. of the men are unemployed, but an amazingly high standard of nutrition is maintained. The few that are under-fed do not suffer from lack of quantity but of quality of food, and this is not because of poverty."

CAUSES OF MALNUTRITION

He was not, Mr. Ramsbotham said, quoting that area as typical of the whole country; it clearly was not the case that the percentage of malnutrition was low in the country as a whole. He quoted it for this reason. It was apparently not generally realised that malnutrition might, and obviously did, occur in certain cases not on account of poverty but on account of unsuitable feeding or organic defects and delicacy. For example, from a recent investigation it was found to be comparatively rare for the brothers and sisters of a malnourished child to show any signs of malnourishment. As regarded the country as a whole, the figures of malnutrition showed little change from last year.

In 1931 the number per 1000 was 11·2, in 1932 it was 10·7, and in 1933 it was 11·1. There was just over 1 per cent. of the children coming within that category, and it would certainly be unreasonable to draw any inference from the fractional increase in 1933 as compared with 1932, but, nevertheless, 10 per 1000 were too many. Increasing and energetic steps were being taken to combat this evil.

PROVISION OF MEALS

The principal factor in the fight to check malnutrition as far as the Board of Education were concerned was obviously the provision of meals by local educational authorities. This year 190 out of 316 authorities had exercised the powers under the school feeding sections of the Education Act, and it was expected that ten more were shortly to adopt those powers. Those authorities covered about 70 per cent. of the school population of England and Wales, and as they were almost entirely authorities in industrial areas, somewhere between 90 and 100 per cent. of the children in industrial areas were covered by authorities which exercised those powers.

The others were mainly in rural areas or in seaside or small country towns where the experience of the Board went to show that the problem of malnutrition was of small or negligible proportions. The Board had not allowed the financial stringency of the time to impede the desires of local authorities to spend money on the provision of meals on which they paid the grant at the rate of 50 per cent. In 1928 the net expenditure of the authorities on this service was £227,000; last year it was £560,000. In 1928 the number of authorities exercising their powers in this matter was 145; last year it was 190; and this number was to be increased by about ten more. In February of this year the authorities were feeding about 292,000 children either with ordinary meals or milk, and about 212,000 of these were being fed free of charge, so that although only 1 per cent. of the public elementary schoolchildren were reported to be suffering definitely from malnutrition, free meals and milk were being provided for over 4 per cent.

In addition, there were about 900,000 children receiving one-third of a pint of milk daily for the payment of one penny under voluntary schemes organised by the National Milk Publicity Council.

SELECTIVE FEEDING

It had been represented to him that all local educational authorities should be urged to provide free dinners for the children of the poorer classes. In view of the large expense involved, that course could not be justified unless it was clearly established that the existing permissive arrangements were inadequate. He did not think that that was the case. The principle was that the expenditure on the provision of meals out of educational funds should be related to the educational capacity of the children, and should be based on a selection by school medical officers of the children, supplemented by reports from their teachers.

Such selection should include not only children definitely malnourished, but children who also showed any symptoms of subnormal nutrition. To make the provision of meals universal for all poor children would contradict that principle, and impose on local education authorities the duty of supplementing out of educational funds the assistance given from other sources for the relief of economic distress. In any event, the experience of some of the most distressed areas showed that it was possible to keep malnutrition in check by providing dinners, or even milk only, under a system of medical selection, which would include all children suffering from subnormal nutrition, but not those children who, though poor, were able to take advantage of the education offered to them.

NO EMBARGO ON NEW SERVICES

He had seen from time to time in the educational press suggestions that the Board was placing an embargo on various services for improving the physical condition of the children. No such embargo had or was being placed on the school medical service. Last year they approved 17 proposals for new clinics, and 124 forms of inspection and treatment, including the appointment of additional medical officers, dentists or specialists, school nurses, the equipment of clinics, and many other forms of expenditure, and this year they had allowed in the Estimates for an increase in the cost of the school medical service.

CRITICISM OF THE BOARD

Mr. COVE said that many black-listed schools still existed throughout the country. Teachers were supposed to teach the children cleanliness and hygiene when the physical conditions in the school were filthy in the extreme. He begged the Parliamentary Secretary not to be content with the reports sent him about the physical condition of the children, but to make investigation which would reassure the country that the children were not being ill-fed. He quoted the recent investigation in Newcastle (see THE LANCET, May 12th, p. 1029) into the physical condition of children from 2–5 years, which showed that nearly half the children in the poorer class were below the standard height compared with only 5 per cent. among the better-class children; and that 49 of the 125 poorer children had suffered from chest trouble, compared with 5 of the 124 better-class children. This investigation, he claimed, showed that there was tremendous need for better attention to the physical needs and general well-being of young children.

Dr. G. MORRISON said he understood that some education authorities were willing to lend the services of their medical officers for the junior instruction centres. He was glad to hear that the Board was not likely to be niggardly in the matter, but would look with an indulgent eye on schemes for providing medical services for those who were not insured under the National Health Insurance scheme.

Viscountess ASTOR said children between two and five years of age should be the special concern of the country. There was a gap between those ages in the medical care and treatment of young children. Splendid progress in infant welfare work had been made, but the children from two to five years of age in overcrowded areas were being neglected, although one knew the remedies. In 1931 progress was being made in the establishment of nursery schools, but it was stopped by the Economy Act. There were 5000 children in the open-air nursery schools, while 174,000 children between two and four years of age were living under slum conditions. She urged the Government to restore the cuts imposed on nursery schools, which were a vital necessity.

Mr. RAMSBOTHAM said that within the last month or two the Board had authorised two more nursery schools, and there was nothing to prevent local authorities submitting fresh proposals.

Hospitals and Prize Competitions

In the House of Lords on May 31st Lord LUKE moved to insert the following new subsection in the Betting and Lotteries Bill:—

> Notwithstanding anything contained in this section a corporate body established before the passing of this Act for a charitable purpose may conduct for any such purpose any competition in which success depends partly upon the exercise of skill (other than a competition such as is referred to in paragraph (a) of subsection (1) of this section) in respect of which such corporate body shall have submitted to the chief officer of police of the area in which their principal office is situate a copy of the rules and conditions of the competition together with the opinion of counsel that success in the competition depends to a substantial degree upon the exercise of skill and the chief officer of police shall not within fourteen days after such submission have intimated his disagreement with such opinion.

They were very anxious, he said, to preserve for the hospitals this potent source of revenue which seemed to be threatened under the provisions of the clause. The ambiguous word was "substantial" as introduced in defining the amount of skill required to keep a competition within the law, and the amendment provided for a decision as to the legality of competitions run by charitable bodies before the charity concerned had incurred the expense of launching the competition. It was very undesirable that voluntary workers endeavouring to raise funds for a charity should be open to prosecution and penalties when they were acting in accordance with the best legal advice obtainable. It was equally undesirable that the charity for which they were acting should incur the risk of losing several thousands of pounds which might have been spent in printing and advertising. Unless the amendment, or some other provision on similar lines, was embodied in the Bill, it would mean that charitable bodies must either face the above risks or forego an important source of revenue.

The British Charities Association, said Lord Luke, had run competitions for 10 years. Last year they distributed £21,000 to the hospitals, which brought their total distribution to over 900 hospitals up and down the country to about £250,000. Their competitions had usually been part skill and part chance, but not one of them had ever been challenged in the Courts. It would be impossible to run a competition entirely dependent on skill if they were going to allot prizes, because they could not define skill down to, say, one-hundredth-thousandth part, and that would be necessary when they had over 100,000 competitors. There was bound to be a considerable element of chance, but the competitor usually thought that his skill was a more important factor than it really was, and if it was the moral aspect that the Bill was dealing with, that was important. Prize competitions for charity were both popular and harmless, and charities could ill-afford at the present moment to be deprived of this source of income. The position of a hospital, or other charitable body, running a competition after the passing of the Bill, if it was unamended, would be that it would run the risk of an action to show whether the skill element was substantial or not. If the competition had started, this action might come at a critical time and cause loss to the organisation whether the skill was proved to be substantial or not. As the charity depended on the public sending in 6*d.* or 1*s.* entrance money, the mere talk of litigation would spoil the chance of success. Another point was that the views of magistrates might differ very much as to what was a "substantial" amount of skill, possibly due to their holding varying views as to the morality even of a competition.

Charitable bodies, Lord Luke concluded, could not take the risk of a gamble as to whom their case would be tried before, especially when there was no yardstick by which they could gauge the amount of skill required. The amendment sought to settle the matter before the charity started operations.

GOVERNMENT REPLY

The Marquess of LONDONDERRY said that the amendment was designed to provide machinery to enable the legality of these competitions promoted by charitable bodies to be determined in advance. One could sympathise with the desire that the British Charities Association should be allowed to promote competitions without the risk of legal proceedings, but the question whether any particular competition was or was not legal could be decided only by the Courts.

Milk and Public Health

On May 31st the House of Commons went into Committee on the money resolution in connexion with the Milk Bill.

STATEMENT BY THE MINISTER OF AGRICULTURE

Mr. ELLIOT said that the objects which the Government sought to achieve were a bigger consumption of milk and the cleaning up of the herds. The short-range policy consisted of emergency advances for putting a bottom into the market for manufactured milk, and the long-range policy was the cleaning up of the herds and, based upon that, a campaign of publicity and, if possible, of cheapness for increasing the consumption of milk and thereby dealing with the present glut. The committee of the Economic Advisory Council rightly stated in their recent report that the total eradication of bovine tuberculosis from all herds was the only complete solution of the problem of tuberculous milk. This solution could not be reached for many years, and without considerable expenditure, but, as at present advised, the Government proposed to use £750,000 primarily for making a start. He agreed with Dr. John Orr that the present position of the dairy cows was a reproach both to the Department of Health and to the Department of Agriculture. If the country had paid half the attention to the improvement of the milk-supply that it had paid to many far less urgent and important questions, this reproach would not lie at our door to-day compared with other countries. The resolution also authorised a contribution of £1,000,000 from the Exchequer on a £-for-£ basis for two years in order to increase the demand for milk. The Milk Marketing Boards would contribute the other pound. Programmes submitted by the Boards would not be approved unless they contained provision for the supply of milk to schools at reduced rates.

Mr. T. WILLIAMS said the Opposition agreed that the country ought to set to work to clean up its herds and to provide a pure milk-supply, but if millions were to be hurled away he thought they should be spent in providing the children with free milk. The Government started at the wrong end. They would not clean up the herds so long as they left the task in the hands of county councils run by farmers and landowners. A nationally organised service was required.

Mr. DE ROTHSCHILD felt grave apprehension lest the adoption of pasteurised milk should retard progress towards a pure natural milk-supply. The present conflict in medical opinion on pasteurisation might be very sincere, but it was worrying the milk-consuming public. He suggested that part of the money voted should be given to experiments in schools which would conclusively show the relative values of raw, pasteurised, and T.T. milk.

SCHOOL-CHILDREN AND SURPLUS MILK

Sir E. GREGG said he believed the supply of milk to school-children could be made to consume something like 300,000 gallons a day, or 9,000,000 gallons a month, which would account for the greater part of the Marketing Board's surplus: and if, in addition, milk was given to infants not yet of school age and to nursing mothers the whole of the surplus could be used very effectively indeed. He suggested the establishment of something in the nature of a new children's health insurance fund to which contributions should be paid by the milk industry and by the parents and made up as far as was necessary by the Government. A measure of that kind, while of the greatest value to the children, would remove discrimination between those whose parents could afford to pay and those who could not.

Sir F. ACLAND was afraid that if the proposal of distributing milk to schools was rushed some medical officer would say that a child had acquired tuberculosis through drinking milk. That would do away with all the good of the publicity campaign. He would much rather put the scheme off for a year or two until they could be certain of an adequate supply of really tubercle-free milk.

Mr. SKELTON (Under-Secretary of State for Scotland): Does the right hon. gentleman apply the same principle to the supply of milk to children in their own homes?

Sir F. ACLAND said he did not. He thought a great deal more good was done by getting more milk drunk than by saying that nobody should ever drink milk which had not been approved by all the medical authorities in the country. He thought many medical officers of health overdid their pursuit of pasteurisation and so on.

Captain HEILGERS, speaking as a producer of Grade "A" milk, said he thought doctors had done a tremendous amount to kill the production of clean milk in this country. By crabbing the milk-supply day in and day out the medical profession had made it most difficult to enable the Milk Marketing Board to raise the sales of liquid milk in this country. By plumping for pasteurisation, and imperfect pasteurisation such as existed to-day, medical men had played into the hands of the milk distributors. He agreed that a pre-pasteurisation standard was needed, but farmers could not be forced to produce cleaner milk unless they got a proper reward. It would be a great thing to clear tuberculosis from the country, but he felt that medical men had not given milk producers a fair deal as regarded the dangers which they had represented as arising from tuberculosis. The odds were 2200 to 1 in any year against any child getting tuberculosis, and the mortality-rate for measles, whooping-cough, diphtheria, and other diseases was much greater.

MILK-BORNE DISEASE

Sir F. **FREMANTLE** said no one who knew anything about this subject would wish to intensify the fears of people in regard to infection from milk; on the other hand, those who tried to belittle the amount of disease which might arise were doing the worst possible injury to the dairy industry.

> The milk commission of the People's League of Health had pointed out that at least 40 per cent. of the cows in this country are infected with tuberculosis, and that at least one in every 100 cows is actively discharging tubercle bacilli into the milk or elsewhere. According to the commission anything from 5 to 13 per cent. of the milk sold for human food contains living, virulent tubercle bacilli, while on the human side about 2000 deaths in England and Wales, mostly in children, occur annually from infections with the bovine bacillus . . . with not less than 4000 fresh cases each year.

It was absurd to say that the medical profession ought not to pay any attention to the comparatively small amount of tuberculous milk; it was no use saying that the risk ought to be taken. But there were certain devices which were perfectly possible. The problem of pasteurisation, indeed, seemed to be solving itself, since about 95 per cent. of the milk which came into London for consumption was pasteurised. At the same time, the proper use of these methods required a good deal of intelligence and ingenuity. If milk was provided for schools it would be done under the authority of either the school medical officer or of the medical officer of health, who would have to consider how it should be rendered safe. He believed that the greater number of them would say that it was possible to pasteurise milk cheaply, and that in any case the nutritive value of the milk would be infinitely to the advantage of the children, and they would desire to give them as large a supply as could be allotted. In improving present conditions the short-term policy was represented by measures such as the pasteurisation or boiling of milk. The long-term policy was that of the eradication of tubercle from the herds. It would be a mistake to suppose either that this was an impossible task, or that it could be done in a year or two. It would be very difficult, but he believed it could be achieved.

After further debate the resolution was agreed to by 177 to 43.

Price of Insulin

In the House of Commons on June 4th, on a Finance Bill amendment to place insulin on the free list, Mr. Herbert Williams appealed to the Chancellor not to remit the duty of 33⅓ per cent., because it assured home supplies if for any reason supplies from abroad should be cut off, and it afforded protection against a possible monopoly by a foreign firm. Mr. Chamberlain replied that the imposition of the duty was in fact an accident. It had followed the success of a contention not to obtain a duty upon insulin but to obtain a proper definition of dutiable fine chemicals. The manufacturers of insulin had certainly not exploited the public, but he had become aware of a feeling among diabetics that they were paying more than if there had been no duty. To them insulin was a matter of life and death, and he was unwilling to leave them with the shadow of a grievance. If injury resulted British manufacturers could still apply to the advisory committee for a new duty.

HOUSE OF COMMONS

THURSDAY, MAY 31ST

Animals Slaughtered under Tuberculosis Order

Captain **HEILGERS** asked the Minister of Agriculture the amount paid in compensation for animals slaughtered under the Tuberculosis Order of 1925 for the year 1933.—Mr. **ELLIOT** replied: The total sum paid in compensation for animals slaughtered under the Order in 1933 was £71,827.

Purity of Water in Swimming Baths

Mr. D. G. **SOMERVILLE** asked the Minister of Health whether he would consider the desirability of suggesting to all local authorities possessed of swimming baths the necessity of insisting upon a rigid standard of purity of the water.—Mr. **SHAKESPEARE** (Parliamentary Secretary to the Ministry of Health) replied: A report on the purification of water in swimming baths was prepared by the Ministry in 1929. The report emphasised the importance of clean water in public baths, and explained the best method of purification. Local authorities are well aware of the recommendations in the report, and my right hon. friend proposes again to call attention to them in the forthcoming annual report of the Ministry.

Use of Fresh Cream in Ice-cream

Lieut.-Colonel **ACLAND-TROYTE** asked the Minister of Health whether he would bring in legislation or regulations to ensure that no article must be sold as ice-cream which was not made from fresh cream.—Mr. **SHAKESPEARE** replied: My right hon. friend has no power to make regulations to the effect suggested, and he could not undertake to introduce legislation to deal solely with this matter. The general question of legislation to enable definitions of articles of food to be prescribed is receiving consideration in connexion with the recommendations of the Departmental Committee on the Composition and Description of Food which has recently reported.

Fatal Bicycle Accidents to Children

Mr. **ANSTRUTHER-GRAY** asked the Minister of Transport whether, in view of the large number of fatal bicycle accidents to children under 16, he had considered the need for an age limit under which children must not ride bicycles on the public roads.—Lieut.-Colonel **HEADLAM** (Parliamentary Secretary to the Ministry of Transport) replied: The number of bicycle accidents to young people is a matter of great regret, but I think that the adoption of a minimum age limit for cyclists would impose an unjustifiable degree of hardship on a large number of persons.

Physical Condition of Naval Recruits

Sir **ROBERT GOWER** asked the First Lord of the Admiralty how many boys and men respectively were accepted in the year 1933 for His Majesty's Navy and Royal Marines respectively; how many were rejected on account of some physical deficiency; and what was the corresponding percentages of rejections to acceptances in the years 1929, 1930, 1931, and 1932 respectively.—Sir **BOLTON EYRES-MONSELL** replied: The following is a statement showing the number of boys and men entered in the Royal Navy and Royal Marines during the year April 1st, 1933, to March 31st, 1934:—

	R.N.	R.M.
Boys	2607	132
Men	3219	402

Of 11,645 medically examined, 4524 were rejected on account of some physical deficiency. The corresponding percentages of rejections to acceptances during the years in question were:—

1929–30	40·65	1931–32	43·33
1930–31	40·33	1932–33	41·00

MONDAY, JUNE 4TH

Vaccination of Naval Ratings

Mr. **GROVES** asked the First Lord of the Admiralty whether, in view of the terms of No. 12 of the King's Regulations, Article 1417, relative to vaccination, it was the practice to allow persons to enter the service who were conscientious objectors to vaccination.—Sir B. **EYRES-MONSELL** replied: No, Sir. All candidates on entry are required to declare their willingness to be vaccinated or revaccinated and inoculated, if necessary, otherwise they are not accepted for entry.

Fat Content of Tinned Cream

Mr. **TEMPLE MORRIS** asked the Minister of Health whether he was aware that tinned cream, labelled thick cream but containing only about 20 per cent. of cream, was being sold in different parts of the country; and whether this practice was approved by his department.—Sir **HILTON YOUNG** replied: I am aware that tinned cream containing about 20 per cent. of milk fat is sometimes labelled as thick cream. The question whether this is a false description is one for the consideration of the Courts in the event of proceedings being taken under the Food and Drugs (Adulteration) Act. The matter is not one in which I am empowered to take action.

TUESDAY, JUNE 5TH

Ventilation of the House of Commons

Mr. BERNAYS asked the First Commissioner of Works whether he was satisfied that every possible effort had been made to improve the ventilation of the House of Commons.—Mr. ORMSBY-GORE replied: A very comprehensive engineering report on this subject was presented to Parliament in June, 1931, as Command Paper No. 3871 of that year. This report is available in the sale office. I have recently had analyses made of the air in the chamber and lobbies at different times of the day, and I am sending the hon. Member a copy of the Government Chemist's report. I am further carrying out a similar but more complete survey of the ventilation of the whole building, as a result of which I hope it may be possible for more definite conclusions to be reached.

Mr. BERNAYS asked if it was not the fact that the atmosphere of the House compared very badly with that of any cinemas in the country?

Mr. ORMSBY-GORE said that that was certainly his own impression, but all the scientific and technical experts who had investigated the matter found to the contrary.

Elimination of Noise from Aeroplanes

Mr. BERNAYS asked the Under-Secretary of State for Air whether he would consider the introduction of legislation making the use of silencers obligatory on privately owned aeroplanes.—Sir P. SASSOON replied: No, Sir. My noble friend is wholly in sympathy with the object in view—namely, the elimination of all avoidable noise in flying; but it would be altogether premature at present, and indeed useless, to make the fitting of silencers legally obligatory. Silencers would diminish the noise from the engine, but would not affect that from the propeller, and they would have the disadvantages at once of impairing the efficiency of the aircraft and of increasing the risk of fire. The whole question is under active consideration and it is hoped that the technical progress which has been and is continuing to be made will have the effect eventually of solving this very difficult problem.

MEDICAL NEWS

University of Oxford

The degree of doctor of medicine has been conferred on K. N. Irvine.

University of London

Prof. G. E. Gask and Mr. H. L. Eason have been appointed governors of the British Post-Graduate Medical School.

Applications for the William Julius Mickle Fellowship should reach the principal of the university not later than Oct. 1st. This fellowship is awarded annually to the man or woman who has done most to advance medical art or science in the preceding five years. Candidates must be graduates of the university and resident in London. Essays for the Paul Philip Reitlinger prize should reach the University not later than Oct. 1st. They should embody the result of some research work on a medical subject carried out by the candidate. Further particulars of both these awards may be had from the academic registrar.

University of Wales

At recent examinations the following candidates were successful:—

TUBERCULOUS DISEASES DIPLOMA

P. K. Ghosh, M.B. Calcutta; B. K. Pal, M.B. Calcutta; H. K. B. Rustogi, M.B. Lucknow; P. K. Sen, M.D. Berlin; and H. A. Zaki, M.B. Cairo.

Society of Apothecaries of London

Dr. Marjorie Houghton James has satisfied the examiners for the Mastery of Midwifery.

King Edward VII. Hospital, Windsor

At the annual meeting of this hospital last week it was stated that the strain of road accidents had compelled the provision of further accommodation. There is pressing need for an eye ward, owing to the great increase in the number of ophthalmic cases urgently requiring treatment. There is a deficiency of about £15,000, and there is still need that £2500 should be found for the new buildings. The result of 25,000 letters of appeal was £2324.

Fellowship of Medicine and Post-Graduate Medical Association

The next lecture-demonstrations in the series being given by Dr. A. E. Clark-Kennedy at the Medical Society of London, 11, Chandos-street, Cavendish-square, W., will be on œdema and diuretics (Tuesday, June 12th), and renal insufficiency (June 19th). Forthcoming courses include proctology, at St. Mark's Hospital, from June 11th to 16th; medicine, surgery, and the specialties, at the Prince of Wales's Hospital, from June 11th to 23rd and again from June 25th to July 7th; cardiology, at the National Heart Hospital, June 25th to July 7th; diseases of children, at the Children's Clinic, June 25th to July 7th; ophthalmology, at the Central London Ophthalmic Hospital, July 2nd to 7th; and a week-end course in medicine and surgery, at the Metropolitan Hospital, June 30th and July 1st.

St. Thomas's Hospital Medical School

The prizes of the school will be distributed on Tuesday, June 26th, by the Earl of Derby, in the Governor's Hall of the hospital.

Tour in the South of France

The medical faculty of Bordeaux and the medical, thermal, and climatic federation of the Pyrenees have arranged their third tour in this region for men of medicine and science. The party will leave Périguex on August 26th, and the itinerary will include Bordeaux, Dax, Biarritz, and Bayonne. Pau will be reached on Sept. 3rd. A short tour (Sept. 3rd–6th) in the Pyrenees has been arranged and Pau will be the starting-point. Further particulars may be had from Dr. M. Faure, at La Malou (Hérault).

London Hospital Medical College

It is announced that the Queen has consented to open the new students' hostel of this college on Tuesday, July 3rd, at 3.30 P.M. The sum of £15,000 has been collected towards the building, but another £17,000 is required if the hostel is to start free from debt. It stands on hospital ground and the architect is Mr. Edward Maufe. A short article on the project has already appeared in THE LANCET (1932, ii., 1080).

The late Dr. Bernard Hollander

A meeting will be held in the Essex Hall, Strand, London, on Tuesday next, June 12th, at 7 P.M., when addresses will be delivered in memory of the late Dr. Bernard Hollander. The meeting is organised by the British Phrenological Society, and those attending it will be addressed by Dr. Hubert J. Norman, Mr. J. P. Gilmour, and Mrs. C. Stackpool O'Dell, dealing respectively with Dr. Hollander's work as physician, rationalist, and phrenologist. The chair will be taken by Mr. C. E. Sewell, and admission to the meeting is free, a collection being taken up to defray expenses only.

Royal Society of Medicine

Section of Radiology.—The annual dinner of this section was held on June 1st, Dr. R. S. Paterson, the president, being in the chair. He proposed the health of the guests, coupled with the name of Mr. W. H. Collins. Mr. Collins hoped that nobody would be jealous of the Middlesex Hospital, but always realise that its department of radiology—which they hoped would be the finest in the country—was open to everybody. That hospital was very fortunate in having Dr. Graham Hodgson to run the department. Dr. Robert Hutchison proposed the Section of Radiology. He said he always liked to send his cases to a sympathetic radiologist—one who would let the physician down gently. The section was in a vigorous condition, and represented one of the great advancing lines in medicine. Dr. F. Hernaman-Johnson said that it now had nearly 300 members. He suggested the provision of a presidential robe for each section, Surgery having a gown decorated with knives and coffins, and Radiology showing healing angels.

A Discussion on Malnutrition

As already announced, Sir Gowland Hopkins will take the chair at a meeting arranged by the Committee Against Malnutrition, which will be held at 8 P.M. on Wednesday next at 34, Red Lion-square, London, W.C. The speakers will include Dr. Stella Churchill, Prof. J. B. S. Haldane, Dr. R. D. Lawrence, and Dr. R. A. Lyster. Tickets may be had from the hon. secretary of the committee at 19c, Eagle-street, W.C.1.

Payment of Medical Staffs in South Africa

The Orange Free State Provincial Administration is considering the advisability of paying a small salary, or retaining fee, to all doctors at present giving honorary service in the provincial hospitals. During the past year or two the number of free patients in the hospitals has grown steadily, with the result that the honorary physicians have found it very difficult to cope with the cases. The suggestion is made that if the honorary medical staff was remunerated to some extent the hospital managements would have more control and an opportunity of introducing effective organisation regarding poor patients.

Scottish Medical Golfing Society

This society has just been formed for the benefit of Scottish members of the medical profession in the London area. The president is Dr. Bertram Shires; the vice-presidents, Sir Ashley Mackintosh, Sir Robert Muir, Prof. James Musgrove, Sir Harold Stiles; the hon. treasurer, Dr. Bruce Williamson; and the hon. secretaries, Mr. Norman Fleming and Dr. Burton Yule. Doctors desiring to apply for membership for the above society are requested to communicate with the senior honorary secretary at 92, Harley-street, London, W.1, mentioning club and handicap.

Medical Reunion in Vienna

A committee of Viennese physicians are making arrangements to hold an informal reunion from July 9th to 15th in Vienna, primarily of medical men who have received the whole or part of their training in that city. Members of the profession who have trained elsewhere will, however, also be welcome. Scientific meetings and discussions will be held and visits will be paid to hospitals; there will also be social meetings and excursions. Special travel and accommodation rates will be offered to doctors and their families attending the reunion. Further particulars may be had from the Austrian Federal Railways, 31, Lower Regent-street, London, W.1.

Society for the Provision of Birth Control Clinics

On Tuesday next, June 12th, a lecture will be delivered on the theory and practice of contraception at this centre, 153a, East-street, London, S.E.17, by Dr. Gladys Cox. Practitioners and medical students who have completed their gynæcological course are invited to the lecture. Practical demonstrations in technique will also be open to the same audience on Tuesday, June 19th, at 6 P.M. and at 7 P.M., and on Tuesday, June 26th, at the same hours. Those wishing to attend these demonstrations should bring rubber gloves with them, and a fee of 2*s.* 6*d.* is charged for admission. Tickets should be applied for in advance at the Walworth Centre of the Society for the Provision of Birth Control Clinics.

Welfare of the Deaf

Sir Hilton Young, the Minister of Health, received a deputation on May 30th from the National Institute for the Deaf, the Counties Associations for the Deaf, the National College of Teachers of the Deaf, the Council of Church Missioners to the Deaf, and the British Deaf and Dumb Association. The object of the deputation, which was introduced by Lord Charnwood, was to suggest the necessity for legislation to make the welfare of the deaf the duty of local authorities, and to ask for the appointment of an advisory committee on the deaf. The Minister said that he was in full sympathy with the desire of the deputation to promote the welfare of the deaf to the fullest possible extent. He believed, however, that progress was to be sought *not* in the imposition of compulsory duties on local authorities but in the encouragement of the work of these authorities and of voluntary agencies on the lines proposed in Circular 1337 issued by his department.

Infants Hospital, Vincent-square

Last week Prince George presided at a dinner at Guildhall in aid of the funds of this hospital. The special appeal produced £10,000. The hospital, it was stated, contains 100 cots, and there are a further 18 at the convalescent home at Burnham; the out-patients' department can deal with 2000 cases a month.

Cowdray Club and College of Nursing

H.M. the Queen visited the Cowdray Club on June 2nd, and inspected the "room of memory," the club's memorial to Annie Viscountess Cowdray, and two new floors of bedrooms. This is part of the provision, rendered possible by the gift of Lady Cowdray in 1932, which included refronting the whole building and substantially enlarging the College.

A Memorial at Leeds

On June 1st, at the General Infirmary at Leeds, Lord Moynihan unveiled a portrait of his father-in-law, Mr. T. R. Jessop, who for 20 years served on the active staff of the infirmary. Mr. Jessop, who died in 1903, described himself as the last of the "general consultants," and to the end of his career saw many medical cases in consultation, though it was as a surgeon that he did his outstanding work. He was the first in England to operate *successfully for sarcoma of the kidney, and recounted his* experience of operations for renal and vesical calculus in the Bradshaw lecture of 1901.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

PADDINGTON MEDICAL SOCIETY.

TUESDAY, June 12th.—9 P.M. (at the Great Western Hotel, Paddington), Dr. W. G. Bendle: The Doctor and His Critics (Presidential Address).

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

THURSDAY, June 14th, and FRIDAY (at the County Hall, Westminster Bridge), Conference on the National Tuberculosis Scheme: the Experience of 21 Years.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, June 12th.—5 P.M., Prof. O. L. V. S. de Wesselow On Arterial Hypertension (last Croonian Lecture).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 11th, to SATURDAY, June 16th.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Afternoon Course in Venereal Disease.—ST. MARK'S HOSPITAL, City-road, E.C. All-day Course in Proctology.—PRINCE OF WALES'S HOSPITAL, Tottenham, N.15. All-day Course in Medicine, Surgery, and the Specialties.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Lecture-demonstration on Œdema and Diuretics by Dr. A. E. Clark-Kennedy, at 2.30 P.M., on Tues
Individual clinics in various
and surgery are available daily.
clinics, &c., arranged by the
are open only to Members and Associates.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

WEDNESDAY, June 13th.—4 P.M., Dr. C. E. Lakin: Demonstration of Medical Cases.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

Daily, 2 P.M., Medical and Surgical Clinics, Operations.

MONDAY, June 11th.—10 A.M., Medical Wards. Pathological Demonstration. 11 A.M., Surgical Wards. 2 P.M., Gynæcological and Surgical Wards, Eye and Gynæcological Clinics.

TUESDAY.—10 A.M., Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Throat, Nose, and Ear Clinic. 4.15 P.M., Lecture, Mr. Green-Armytage: The Menopause.

WEDNESDAY.—10 A.M., Medical and Children's Wards, Children's Clinic. 2 P.M., Eye Clinic.

THURSDAY.—10 A.M., Neurological and Gynæcological Clinics. 11.30 A.M., Fracture Demonstration. 2 P.M., Eye and Genito-urinary Clinics.

FRIDAY.—10 A.M., Skin Clinic. 12 noon, Lecture on Treatment. 2 P.M., Throat Clinic.

SATURDAY.—10 A.M., Medical and Surgical Wards, Children's and Surgical Clinics. The lectures at 4.15 P.M. are open to all medical practitioners without fee.

CHADWICK PUBLIC LECTURES.

THURSDAY, June 14th.—5.30 P.M. (in the Chelsea Physic Garden, Swan Walk, Chelsea). Mr. E. Augustus Bowles: Simples and Herbals. Illustrated by Living Plants.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, June 12th.—3.30 to 5 P.M. (at the General Hospital), Mr. B. T. Rose: Demonstration of O.P. Surgical Cases.

FRIDAY.—3.30 to 5 P.M. (at the Queen's Hospital), Dr. O. Brenner: Rheumatic Heart Disease.

LEEDS GENERAL INFIRMARY.

TUESDAY, June 12th.—3.30 P.M., Mr. La Touche: Radio-surgical Demonstration.

Appointments

HART, P. D'ARCY, M.D., M.R.C.P. Lond., has been appointed Assistant Physician to University College Hospital.

Certifying Surgeons under the Factory and Workshop Acts: MALCOLM, F. J., M.B., Ch.B. Aberd. (Kemnay, Aberdeenshire); SHEPHARD, W. H., L.R.C.P. Lond., M.R.C.S. (Tewkesbury, Gloucestershire).

Vacancies

For further information refer to the advertisement columns

Archway Hospital, Highgate, N.—Temporary Asst. M.O. At rate of £250.
Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.
Bagdad. Royal College of Medicine.—Chair of Materia Medica. Salary at rate of I.D. 960 to I.D. 1200 per annum.
Bath, Royal United Hospital.—Out-Patient and Cas. O. H.S. Each at rate of £150. Also Hon. Med. Reg.
Birmingham City Education Committee.—Asst. School M.O. £500.
Blackburn Royal Infirmary.—Res. Cas. O. £150.
Bristol Eye Hospital.—Asst. Res. H.S. At rate of £100.
Bristol General Hospital.—Sen. Res. M.O. £200. Cas. H.S. At rate of £100. Also Two H.P.'s., Two H.S.'s., Res. Obstet. O., and H.S. to Spec. Depts. Each at rate of £80.
Bristol Royal Infirmary.—Hon. Physician, Hon. Asst. Phy., Hon. Reg. to Orthopædic Dept. Also Hon. Anæsthetist.
Cancer Hospital, Fulham-road, S.W.—Second Asst. Pathologist. £250.
Cardiff, University College of South Wales and Monmouthshire.—Asst. Lecturer in Anatomy. £400. Asst. Lecturer in Physiology. £400. Asst. Lecturer in Histology. £300.
Connaught Hospital, Walthamstow, E.—H.S. At rate of £100.
Delhi, Countess of Dufferin's Fund.—Three Vacancies for Women's Medical Service for India.
Durham C.C.—District Tuber. M.O. £500.
Edinburgh Royal College of Physicians.—Kirk Duncannon Fellowship for Medical Research. £150–£200.
Evelina Hospital for Sick Children, Southwark, S.E.—H.P. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.
Fareham, Hants, Knowle Mental Hospital.—Third Asst. M.O. £350.
Glasgow, Lightburn Joint Hospital, Shettleston.—Res. Physician. £350.
Great Yarmouth General Hospital.—H.S. £140.
Guy's Hospital, London, S.E.—Ophthalmic Surgeon.
Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—H.S. At rate of £100.
Hospital for Sick Children, Great Ormond-street, W.C.—Physician to Skin Department.
Hospital for Tropical Diseases, Gordon-street, W.C.—H.P. At rate of £120.
Hull Royal Infirmary.—Cas. O. At rate of £150.
Ilford, King George Hospital.—Cas. O. At rate of £130.
Indian Medical Service.—Commissions.
Infants Hospital, Vincent-square, Westminster.—Clin. Asst. to Out-patient Dept.
King's College Hospital.—Radium Registrar.
King's Lynn, West Norfolk and King's Lynn General Hospital.—H.P. At rate of £125.
Leeds General Infirmary.—Hon. Asst. Surgeon.
L.C.C.—Radiologist. £1500.
London Jewish Hospital, Stepney Green, E.—Hon. Surgeon.
London University.—Examinerships.
Maidstone, West Kent General Hospital.—H.P. £150.
Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. Surg. O. for St. Ann's Home. £200.
Manchester Royal Children's Hospital.—Asst. Surgeon. £50.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Mansfield, Notts, Harlow Wood Orthopædic Hospital.—Two H.S.'s. Each at rate of £175.
Middlesbrough, North Riding Infirmary.—H.P. At rate of £125.
Mile End Hospital, Bancroft-road, E.—Asst. M.O. £350.
Ministry of Health.—Two Medical Officers. Each £833.
Newcastle-upon-Tyne Hospital for Sick Children.—Res. Surg. O. £250.
Northampton General Hospital.—H.S. to Ear, Nose and Throat Dept. At rate of £150.
Oldham Royal Infirmary.—H.S. At rate of £175.
Plymouth, South Devon and East Cornwall Hospital.—H.P. and H.S. Each at rate of £120.
Portsmouth Royal Hospital.—H.P. and H.S. Each at rate of £130.
Preston County Mental Hospital, Whittingham.—Jun. Asst. M.O. £500.
Preston and County of Lancashire Royal Infirmary.—H.P. Also Special House Surgeon. Salary in each case £150.
Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P., and H.S. Each at rate of £125.
Queen Mary's Hospital for the East End, E.—Cas. O. Also Res. Anæsthetist and H.P. At the rate of £150 and £120 respectively.
Queen's Hospital for Children, Hackney, E.—H.P. and Cas. O. Each at rate of £100. Also Surgeon for Ear, Nose, and Throat Dept.
Reading, Royal Berkshire Hospital.—H.S. £150.
Royal Dental Hospital of London, Leicester-square, W.C.—Hon. Pathologist.
Royal Masonic Hospital, Ravenscourt Park, W.—Res. M.O. £300. Also Res. Surg. O. At rate of £250.
Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £180.
St. Leonard's Hospital, Hoxton-street, Shoreditch, N.—Asst. M.O. £350.
St. Peter's Hospital for Stone, Henrietta-street, W.C.—Hon. Clin. Assts. to Out-Patient Dept.
[illegible]—Med. Reg. £250. Also H.P. and H.S.
[illegible]*tal.*—H.S. Also H.P. Each at rate of £100.
Smethwick County Borough.—Asst. M.O.H. and Asst. School M.O. £500.
Southampton, Royal South Hants and Southampton Hospital.—H.P., Cas. O., Res. Anæsthetist, and H.S. for Ear, Nose, and Throat Dept. Also H.S. Each at rate of £150.
Southend-on-Sea General Hospital.—H.S. At rate of £100.
Stockport Infirmary.—H.S. £150.
Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.S. At rate of £150. Also Hon. Radiologist.
Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.
West Bromwich, Hallam Hospital.—Res. H.P. At rate of £200.
West London Hospital, Hammersmith-road, W.—H.P., H.S. and Res. Anæsthetist. Each at rate of £100.
Willesden General Hospital, N.W.—Cas. O. and H.S. Each at rate of £100. Also Clin. Assts. to Out-patients' Dept.
Wolverhampton and Midland Counties Eye Infirmary.—H.S. £150.
Wolverhampton Royal Hospital.—H.S. for Orthopædic and Fracture Dept. At rate of £100.
Worksop, Victoria Hospital.—H.S. £170.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons at Bolton North, Lancs; Halesworth, Suffolk; Sheffield West, Yorks; New Cumnock, Ayrshire; and Stratford-on-Avon, Warwick.

Births, Marriages, and Deaths

BIRTHS

BASHALL.—On May 31st, the wife of Dr. C. J. Bashall, of Burbage, Wilts, of a son.

BLACKWOOD.—On May 29th, at Penlea, Newcastle-on-Tyne, the wife of Frederick A. Blackwood, F.R.C.S. Edin., of a son.

MARRIAGES

BROGDEN—GUYER.—On May 28th, at Seascale, Cumberland. George A. Brodgen, M.D., to Grace Elizabeth, widow of John Fisher Guyer.

REES—SHINNER.—On June 2nd, at St. James's Church, Piccadilly, Edward J. Rees, M.R.C.S., L.R.C.P., to Sylvia Mercy, the only daughter of Mr. and Mrs. Ernest George Shinner, of Hill Barn, Purley Downs, Surrey.

STEWARD—READING.—On June 2nd, at Holy Trinity Church, Marylebone, Graham Villiers Steward, L.R.C.P., M.R.C.S., to Margaret Edith, second daughter of Mr. and Mrs. P. G. Reading, of Arran-road, Catford, S.E.

DEATHS

DIXON.—On June 3rd, at Randolph-gardens, N.W., Captain Alban Dixon, late R.A.M.C., aged 52.

FINUCANE.—On May 31st, at Hurst House, Sedlescombe, Sussex, Morgan Ignatius Finucane, M.R.C.S., L.R.C.P., J.P., Barrister-at-Law, in his 69th year.

KENDRICK.—On May 30th, at St. Medards, Norton-street, Coventry, Captain Horace Herbert Kendrick, M.R.C.S., L.R.C.P., aged 64.

ROBSON.—On June 3rd, at Homefield-road, Chiswick, W., William Waller Constable Robson, M.R.C.S., L.R.C.P. Lond., aged 74.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

JUGGLING WITH FIGURES

IN the *Annales d'hygiène* for March Mr. Auguste Lumière, the biologist, returns to the thesis which, in France at any rate, is becoming more and more associated with his name. While not denying the bacillary origin of tuberculosis, he is convinced that the susceptibility to infection depends chiefly on hereditary qualities. The distribution of tuberculosis in a given area does not, he maintains, depend on infection of one person by another, but on factors which make themselves felt in the distribution of other conditions such as cancer, births, and marriages. Statistics obtained in the town of Lyons seem to him to support his point of view. In the 20-year period 1906–1925, Dr. P. Vigne, this town's medical officer of health, found that as many as 18,121 of the 23,218 houses in Lyons were innocent of any tuberculosis death in the period under review. There were 3963 houses in each of which there had been one tuberculosis death, and 886, in each of which there had been two tuberculosis deaths. The houses with three tuberculosis deaths in each numbered 212, and those with four tuberculosis deaths in each numbered 58. At the bottom of this list there were two houses with seven tuberculosis deaths each, and one house with eight such deaths. Lumière then shows that the distribution of births by houses is remarkably similar. These births, he states, are due only to the play of chance and prove, therefore, that the tuberculosis deaths also are distributed by the same law and are unaffected by hygienic or other conditions. Why it should be assumed that births are distributed by chance it is difficult to see. The birth-rate, it is well known, varies considerably by social status, and therefore the probability of a birth being registered in a house must differ widely from one house to another. In other words this control group cannot possibly be an effective one. Further, the average number of deaths from tuberculosis per house in these data is 0·29 (i.e., 6703 deaths in 23,218 houses); if this figure be used to represent the probability of a case being recorded in a house it can, in fact, be shown by statistical means that the distribution of the cases over the houses is nothing like what would arise by chance. There is in the observations a gross excess of houses containing multiple cases. To presume that the probability is equal for all houses must, of course, be erroneous, for houses must differ in the number, age, sex, and occupation of the inhabitants. But the data provided do not allow a better test to be applied. In his appeal to the laws of chance Lumière appears no more helpful than those whom he condemns for having neglected them. It would, in fact, be interesting to see the distribution by houses of an equal number of cases of a disease that Lumière would accept as infectious—small-pox, for instance. If this should prove similar it would in simple fashion show the fallacy of his method.

BLOOD-SUGAR AND GLYCOSURIA IN GRAVES'S DISEASE

IN a supplement (1934, No. LIV.) to *Acta Medica Scandinavica*, W. T. Andersen reports urine- and blood-sugar studies in 31 patients with exophthalmic goitre. The diagnosis was based on tachycardia, goitre, and tremor, and exophthalmos was not considered a necessary symptom. In all the patients sugar was discovered in the urine in some specimen passed during the day, though it might not amount to more than a trace. Using a similar technique glycosuria was present in only 20 per cent. of normal controls. The fasting blood-sugar level was usually found normal in the goitre patients, but the blood-sugar curve after glucose by mouth was increased in height and in duration, more especially in the severe cases. The investigation suggested that the threshold for glycosuria was a little below normal. After thyroidectomy the abnormalities in blood- and urine-sugar tend to disappear; thus glycosuria has been found to be no longer present, the renal threshold is a little higher, and sugar-tolerance tests show a fall in what were previously the highest curves. The changes in carbohydrate metabolism are held to be explained best by Falta's theory which supposes that the thyroid secretion interferes with glycogen storage in the liver. This leads to increased demands on pancreatic activity, and in a high proportion of cases the response is apparently inadequate to maintain completely normal conditions.

LINES FROM A G.P.

WE published recently (THE LANCET, May 19th, p. 1100) some pleasant "Lines *to* a G.P." extracted from the *St. Mary's Hospital Gazette*. Now Dr. F. L. Nicholls, writing from Fulbourn, has sent us some "Lines *from* a G.P." in which the writer sets out the trials of the general practitioner of olden time—the exact date of their writing is unknown. The first ten lines run as follows:—

> "Luckless he, whom hard fates urge on
> To practice as a country surgeon
> To drag a heavy galling chain
> The slave of all for party gain:
> To ride regardless of all weather
> Thru' frost and snow and hail together
> Sometimes to walk when dark as pitch
> And get a tumble in a ditch
> To smile and bow when sick and tired,
> Considered as a servant hired."

In similar vein the author points out the troubles of general practitioners with neurotic patients and those of surly temper or neurotic temper, and dwells on the grave dilemma where two urgent cases, probably obstetric, summon the practitioner simultaneously to different points of the compass. The irritation caused by constant disturbance at meals and by the petty scale of payment are also made the subject of mournful rhyming. Dr. Nicholls says that the lines will arouse memories in those who look back on country practice 50 or 60 years ago, and for that reason sends them for publication. But their principal interest lies in their suggested attribution, for Dr. Nicholls copied the lines from a scrapbook bearing the date 1876 and the name "Dr. E. Jenner" was appended to them. The introducer of vaccination was born in 1749 and died in 1823, but for some years before he died he practised in London. If in the verses from which we quote the opening sentences he was recording personal experiences they would probably have been written about 140 years ago, unless they are reminiscent. There is nothing by which to date their composition, but it is, surely, improbable that Edward Jenner, an accomplished and erudite man, could have been the author.

MALARIA ACQUIRED IN SYDNEY

MALARIA was made a notifiable disease in New South Wales from March, 1915, to November, 1919. During this period 229 cases were notified, but in only two of them was the infection acquired in the State. Since then a further four indigenous cases have been reported, one of the patients having contracted malaria in Sydney itself. The report of the director-general of public health for New South Wales for the years 1931 and 1932, which has just been issued, contains an account, by Dr. E. L. Morgan, of yet another case of the disease acquired in Sydney. The patient, a girl aged 9 years, was born in Sydney and had never been out of the city. No member of the family of ten was suffering from malaria or had ever been in malarial districts. She was admitted to the Royal Alexandra Hospital for Children in January, 1931, suffering from abdominal pain and frequent rigors, and blood examination showed the presence of numerous benign tertian parasites (*Plasmodium vivax*). Anopheline mosquitoes are known to exist in the vicinity, and it is thought that the infection was carried from some southern Europeans or Asiatics, of whom a small number live in the suburb from which the child comes.

ADDRESSES AND ORIGINAL ARTICLES

OBSERVATIONS ON SOME INJURIES OF THE KNEE-JOINT*

By Naughton Dunn, M.B., Ch.B. Aberd.
LECTURER ON ORTHOPÆDIC SURGERY, THE UNIVERSITY OF BIRMINGHAM

The majority of injuries of the knee as of other joints make a natural and complete recovery without special treatment. Severe strain of the knee is, however, common, because this joint has to sustain body-weight transmitted to it through long levers, and whilst doing so allows a wide range of movement.

The knee-joint consists essentially of the broadened ends of the tibia and femur with a sesamoid bone—the patella—in the extensor apparatus, and two fibrocartilaginous discs interposed between the femur and tibia. Nature has provided it with powerful muscles for its control and strong ligaments on which it largely depends for its stability. Although the muscles form the first line of defence against injury, there seems reason to suppose that severe lesions of the knee may be classified into two main groups: those due to direct injury when the muscles are not on guard or their contractile power has been overcome, and those associated with the effort of the muscles to avert injury. The former includes rupture of ligaments, dislocations, and stellate fracture of the patella—the latter, other lesions of the extensor apparatus, and I think also most lesions of the intra-articular fibrocartilages.

In a previous publication,[1] in reviewing a series of 522 consecutive cases of recurrent or chronic disturbance of the normal mechanism of the knee-joint as a result of injury, I found that 250, or almost one half, were diagnosed as due to a lesion of one or other of the intra-articular fibrocartilages. In 179 the internal and in 71 the external cartilage appeared to be the site of the lesion. Exploration of the joint was carried out in 185 of these cases, and a careful study of the findings at the time of operation revealed two facts which were at variance with the published findings of other observers. These were: (1) the relative frequency of lesions of the external cartilage; (2) the high proportion of the lesions found to be present in the posterior segment of the cartilage.

Relative Frequency of the Site of Lesions

As regards the relative frequency of lesions of the cartilages it has always been agreed that the internal cartilage is more liable to injury than the external. Jones,[2] Martin,[3] Campbell,[4] Henderson,[5] Fisher,[6] MacAusland,[7] Surls and Osgood,[8] and others, in their published writings, find that lesions of the internal are from 15 to 4 times more common than those of the external cartilage. My own statistics showed that the internal cartilage was removed in 139, and the external cartilage in 46 cases. Of these 185 cases, however, a definite lesion of the cartilage was found in only 157: 118 internal, 39 external. The remainder were classified in the notes as "N.D.L."—i.e., no demonstrable lesion. These figures show that, in the cases in which a definite lesion was demonstrated at the time of operating, the relative frequency of injury of the internal cartilage to that of the external was 3 to 1. As this aroused criticism at the time, I have reviewed a further series of 110 consecutive cases operated on for a suspected cartilage injury. A definite lesion was found to be present in 98 of these, the internal semilunar cartilage being involved in 66 and the external in 32. This gives an approximate ratio of 2 to 1. If we combine the two groups of statistics we find:

Total number of cases operated on ..	295
Definite lesions found in 255	86·44%

Of 255 cases with definite lesions:

Internal cartilage was affected in	184 (72·10%).
External ,, ,, ,,	71 (27·84%).

This gives a ratio of 2·6 to 1. What is the explanation of this variance from the findings of other observers? I would suggest that it is more apparent than real, and that where it is real it is due to the difficulty of accurate diagnosis in many lesions of the knee-joint. I am in almost entire agreement with Martin when he writes:

> "I would here wish to emphasise that where a proper diagnosis has been made, the injury is always in the nature of a tear or split, and when such is not found the probability is that a wrong diagnosis has been made, some other structure having been injured."

Surgical text-books usually confine themselves to a description of commonly recognised lesions in relation to particular joints. The patient complains of pain and/or limitation of movement in conditions such as tennis elbow, tenosynovitis, the presence of a palpable ganglion, &c. These conditions are readily diagnosed when they occur in situations where the structures involved are accessible to direct palpation. This, however, is not possible in the case of many of the ligaments, bursæ, &c., apt to be affected by strain of the knee-joint. It is to be noted that in my statistics I have confined myself to lesions which could be demonstrated at the time of operation. Martin failed to demonstrate a lesion in 4·5 per cent. of the cases operated on, and Sir Robert Jones considered definite lesions present in but 117 of 190 cases. In this series I failed to establish a diagnosis in 13·56 per cent. of the cases on which I operated. I have not included cases of hypermobility of the cartilage, as although some undue mobility of the cartilage may have been present, I have felt that this might be a variable factor, so that my experience did not justify me in classifying them as definite lesions.

The second point which interested me was that the very large percentage of the lesions were confined to the posterior half of the cartilage, and that involvement of the anterior half was, when present, usually secondary to this.

Internal cartilage cases.—Total operated upon, 214. Lesions found.

(a) Fracture or detachment in anterior half	35 (16·35%).
(b) ,, ,, ,, posterior ,,	89 (41·59%).
(c) Bucket handle type	60 (28·04%).
(d) No demonstrable lesion	30 (14·02%).

External cartilage cases.—Total operated upon, 81. Lesions found.

(a) Fracture or detachment in anterior half	19 (23·46%).
(b) ,, ,, ,, posterior ,,	40 (49·38%).
(c) Bucket handle type	8 (10·00%).
(d) No demonstrable lesion	10 (12·35%).

Of the 255 definite lesions demonstrated there were:

54	fractures or detachments of anterior half	=21·18%.
129	,, ,, ,, posterior ,,	=50·59%.
68	Bucket handle type	=26·67%.

These tables show in statistical form the site of the lesion found to be present on removal of 214 internal

---

* An address delivered before the American Academy of Orthopædic Surgeons, Chicago, on Jan. 9th.

and 81 external cartilages, and also the percentage in which no lesion of the cartilage could be demonstrated. Of the 255 cases in which a definite lesion was seen 50·59 per cent. were lesions of the posterior half of the cartilage, and 26·67 per cent. an extension of this into the anterior segment, which when complete showed the intercondylar displacement of a section of the cartilage, the anterior and posterior attachments being intact. Fracture or detachment of the anterior half occurred in only 21·18 per cent. of the cases.

It is to be noted in reviewing my cases that not only is the internal more often damaged than the external cartilage, but the inner side of the knee is also more frequently the site of pain and tenderness as a result of strain of other structures. For an explanation of this we depend on a knowledge of the anatomy and physiology of the joint, and an appreciation of the relation of the parts during its complex movements.

Lesions of the Intra-articular Cartilages

Not infrequently a patient will open his consultation with the statement that he has "slipped a cartilage" whereas close investigation reveals no such possibility. It is, however, on a correct diagnosis of the condition of the intra-articular cartilages that successful treatment will frequently depend. A lesion of an intra-articular cartilage may be confidently diagnosed if there is a history of recurrent locking of the joint with pain and tenderness limited to the attachments of one of the cartilages, the joint being normal in function in the intervals between the acute attacks, and no X ray evidence of any abnormality is present. On exploration of the joint, one may find a lesion of the anterior half or a bucket-handle displacement—in which case I believe that it is sufficient to remove the obviously detached portion. If no abnormality is seen, the condition of the posterior portion of the cartilage can only be known by its removal. A lesion of the posterior half is proved if, with peripheral detachment of the anterior half, and slight traction, the main body of the cartilage becomes displaced into the centre of the joint. This would not occur with a normal cartilage. This in my experience is the most common lesion. It would appear to arise as a result of abnormal strain of the flexed knee. This causes a disturbance of the normal relations of the parts, and with the protective action of the muscles coming into play, the posterior segment of the cartilage is nipped, torn, or separated from its peripheral attachment.

Not infrequently a longitudinal tear rather than a *separation* of the true attachment occurs. This means that, after the operation described, a portion of the periphery of the posterior segment of the cartilage is still present, and its attachments may have been loosened as a result of the original injury. As a rule the joint gives no further trouble, and I am inclined to be satisfied when I have dealt with the main lesion. I have, however, notes of several cases in which a recurrence of symptoms necessitated the removal of this portion. I have also notes of cases in which we had a typical history of recurrent displacement of the internal cartilage, and on exploring the joint no lesion of this structure was found. In these cases, if I am perfectly satisfied with my diagnosis, I always explore the outer side of the joint, as on several occasions the patient has very definitely referred all his symptoms to the inner side of the knee when the external cartilage was the site of the lesion.

Another condition which may complicate the question is the fact that both cartilages may have been torn. We know in taking our history that the patient is often indefinite about the side of the joint to which pain was referred at the time of injury, and with recurrent displacements it may also vary. In these cases I always make the diagnosis on the site of tenderness after a recent injury. If the case is seen some time after injury, and no local tenderness is present, I will not operate, but request that the knee be tested and the patient referred for further examination as soon as possible after the next injury. If after a recent injury I find tenderness limited to the line of the inner or outer side of the joint, I advise operation accordingly. That this is not always a safe procedure is illustrated by the following case: A footballer was referred to me with the diagnosis of recurrent displacement of the external cartilage. At the time of my examination tenderness pointed definitely to a lesion on the inner side of the joint, and at operation I found a typical bucket-handle displacement of the internal cartilage, and after its removal closed the joint. It was reported to me that the knee had given way and again locked when the patient was getting out of bed prior to discharge 14 days later. Pain and tenderness were now referred to the outer side of the joint, and exploration revealed a similar lesion of this cartilage. Since operation the knee has resumed and retained normal function. Many of the cases are professional association football players—a game which necessitates abnormal strain of the knee-joint, and my experience is that where the lesion is confined to the cartilages the removal of one or both does not interfere in any way with their athletic activities.

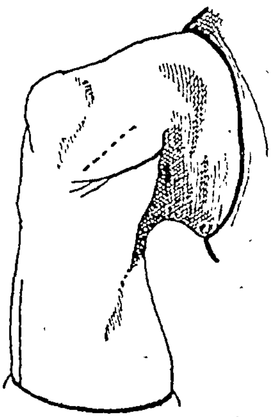

FIG. 1.—Incision advised to obviate complications following division of the patellar branch of the internal saphenous nerve.

To ensure a perfect result I attach considerable importance to the incision used for the removal of the internal meniscus. Care must be taken to avoid division of the patellar branch of the internal saphenous nerve. My attention was first drawn to the importance of this in 1916, when I removed what appeared to be a tender scar which had followed removal of an internal cartilage. The patient returned to France, but reported three months later that he was unable to ride because of pain referred to the femoral condyle on gripping the saddle. Examination revealed a tender nodule at this site which on removal proved to be a neuroma on the patellar nerve branch of the internal saphenous nerve. Since this I have on 12 occasions removed a neuroma of this nerve because of pain following a previous operation for exploration of the inner side of the joint. When this sequela occurs the nerve should be dissected free and avulsed rather than divided, so as to prevent recurrence of symptoms. The essential feature of the incision which I use for removal of the internal cartilage is that it runs parallel with this nerve and allows of its retraction before the capsule is incised. This has the advantages that we cannot get a painful neuroma in the scar or the anæsthesia commonly complained of in the area of distribution of the patellar branch of the internal saphenous nerve. Both are points of great importance in the case of professional footballers, as unless the knee feels absolutely normal confidence in it is unduly delayed (Figs. 1 and 2).

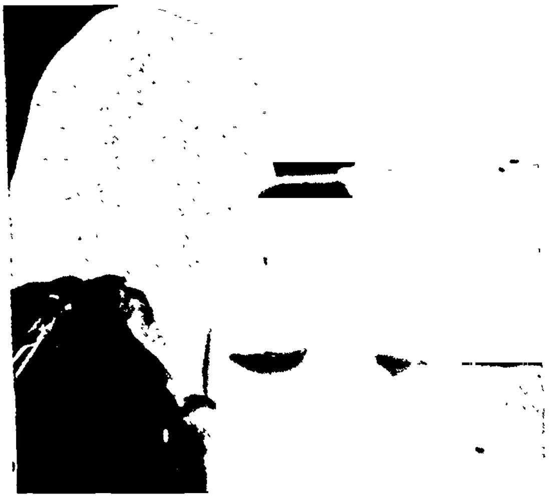

FIG. 2.—Showing avulsion of neuroma of patellar branch of] internal saphenous nerve.

Congenital Abnormalities of the External Cartilage

Before leaving the subject of injuries to the intra-articular cartilages, I wish to refer to congenital abnormalities in the form or attachments of the external cartilage. These are not so very uncommon. Included in this series of 81 cases of external cartilage lesions operated upon are 8 cases—i.e., ten per cent. —in which the history and operative findings suggested a congenital abnormality. The history is usually one of trouble with the knee in early childhood. Not uncommonly this takes the form of an audible snap or "clonk," which appears to be associated with the outer side of the joint on extension. There is seldom much effusion. The condition gives the child little trouble, and at this time the question of operation is frequently delayed. In other cases no symptoms become evident until the child takes part in active games, when apparently without due cause symptoms suggestive of cartilage displacement may arise. The condition is not infrequently bilateral. The following histories are typical, and include the two types of abnormality which I have found present.

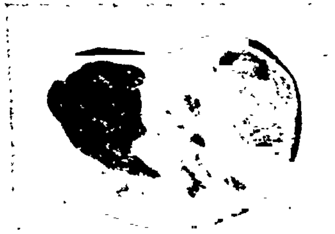

FIG. 3.—Specimen showing congenital abnormality of external semilunar cartilage. The longitudinal split in the posterior half is the result of a recent injury.

CASE 1.—History. Mr. R. was aged 43 when first seen in February, 1931. Left knee: When 9 years old the knee commenced to give way frequently, and a very temporary painless locking occurred. As a result of this he was unable to take part in games. The trouble persisted, and at the age of 19 years locking became more frequent, and was accompanied by pain at the back or outer side of the joint. The last occasion was three weeks previous to examination, when locking persisted for two days. Right knee: The first trouble occurred eight years prior to examination—i.e., when aged 35 years. When turning over in bed with the knee relaxed he felt a sudden pain on the outer side of the joint, and could not straighten it. This happened four times in that year, and was relieved on each occasion after manipulation of the joint under an anæsthetic. The knee had locked on only one occasion since then, but he had worn a bandage constantly and exercised great care in movement.

Clinical examination: Both joints had perfectly free movements, but some pain was referred to their outer sides on forcing flexion and internal rotation. There was no local tenderness apart from slight tenderness over the attachments of the posterior third of the outer cartilage of the left knee. The X rays revealed no abnormality. Operation: The condition found at operation was: on the left side the external cartilage consisted of two fusiform fibrocartilaginous bodies representing the anterior and posterior segments of the cartilage. These were united in the middle by fibrous tissue. They appeared to have no peripheral attachment, but the cornua had slender fibrous attachments to the neighbourhood of the spine of the tibia. The external cartilage of the right knee had a similar form, but the posterior segment had been displaced in front of the condyle of the femur. As a result of the removal of these structures this man, at the age of 44, was enabled to take part in ordinary games for the first time without trouble.

CASE 2.—This case illustrates the second type of abnormality. I have found it present in three cases, in one of which it was bilateral. The case, from which I show the specimen removed, was operated on in my service by Mr. A. M. Hendry on Dec. 8th, 1933 (Fig. 3). The patient, a woman aged 31, was first seen on Nov. 23rd, 1933.

History: Her history was that as a child she had some indefinite trouble with the right knee. Six years ago she had a direct injury to the knee, and since this had occasionally had pain referred to the back and outer sides of the joint on twisting it, accompanied by temporary difficulty in obtaining full extension. Nine months ago she commenced to get aching pain in the knee and had been unable to straighten it fully since. On examination all movements were free, except extension which was limited by 30 degrees. Definite tenderness limited to the line of the external cartilage was present. X ray did not show any abnormality of the joint. Operation: At operation on opening the outer side of the joint it was at once noted that the cartilage was abnormal. It consisted of a complete flat disc about one-fifth of an inch thick, extending from the periphery to the centre of the joint. On dividing the peripheral attachment of the anterior third, the complete disc was readily displaced in front of the condyle. The appearance of the peripheral portion.

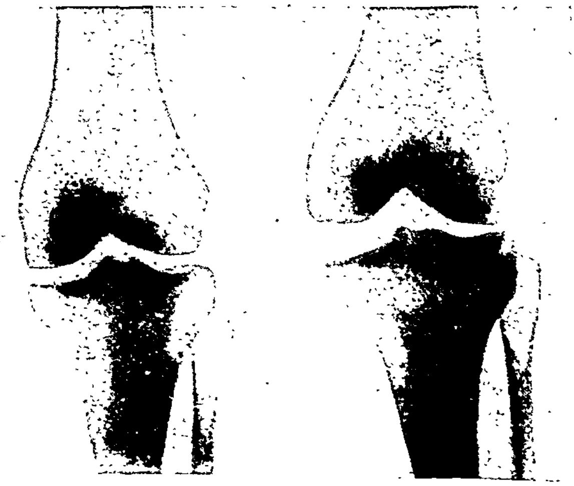

FIG. 4.—Radiogram showing laxity of knee-joint due to rupture of internal lateral ligament.

of the posterior two-thirds suggested that its attachments had been previously ruptured. Division of the attachment in the neighbourhood of the spine of the tibia allowed removal of the complete disc. It is to be noted that although the articular surface of the femur was separated from direct contact with that of the tibia, the radiograms showed no abnormal widening of the joint space.

I have removed an external cartilage from the knee of a child of 4 because of the anxiety of the mother, and from experience of cases in later life I would suggest that operation is advisable in young children if symptoms suggestive of a congenital abnormality of this cartilage are present. The presence of these abnormalities suggests that the condition of cystic degeneration of the external cartilage may also be congenital in origin.

Although inability to extend the knee completely is not uncommonly noted after disturbance of the normal relations of an intra-articular cartilage, we find that it is also one of the most common sequelæ of any severe injury of the knee-joint. Where this is not caused by a definite intra-articular obstruction, the position of slight flexion is due to the instinctive effort of the patient to avoid pain in many conditions which may simulate a lesion of an intra-articular cartilage. Again we find the inner side of the knee more frequently the site of pain than the outer. This side of the joint would appear to be more liable to strain because of the normal inclination inwards of the femur on the tibia, the greater range of movement of the inner condyle of the femur, and the fact that the outer side of the joint is more exposed to the application of external forces.

Lesions of the Lateral Ligaments

Strain of the internal lateral ligament is in my experience five times as common as that of the external lateral ligament, but it is more rarely completely ruptured. The symptoms may closely resemble those of a cartilage lesion. There is severe pain referred to the inner side of the joint—a feeling of something tearing, and pain on attempting to straighten the knee fully. This limitation of extension differs from the locking due to a cartilage displacement in that it disappears under anæsthesia, and would seem to be associated with the fact that the ligament being taut in extension, the position of relaxation is instinctively adopted to obviate strain of its attachments. In reviewing 34 consecutive cases of severe strain of this ligament, none was associated with a lesion of the cartilage requiring operative treatment, except one in which the anterior crucial ligament was also ruptured. Strain of the internal lateral ligament is accompanied by tenderness in the line of the internal cartilage (Fig. 4), but the maximum tenderness is usually over one or other of the attachments of the ligament, most frequently the femoral. The treatment consists of pressure over this point, slight elevation of the heel of the boot to maintain relaxation, elevation of the sole and heel of the boot on the inner side to divert body-weight to the outer side of the joint, with electrical treatment to restore the tone and volume of the vastus internus muscle. Treatment on these lines must be continued until local tenderness has entirely gone, and no pain is elicited on forcing any movement. If the joint is subjected to strain before its normal control and movement have been established, recurrence of the same strain of symptoms is to be expected, and suspicion of cartilage injury again aroused. Lesions of the external lateral ligament are less common than those of the internal lateral ligament. In my experience it is most frequently completely ruptured, when surgical treatment is necessary to restore stability of the joint.

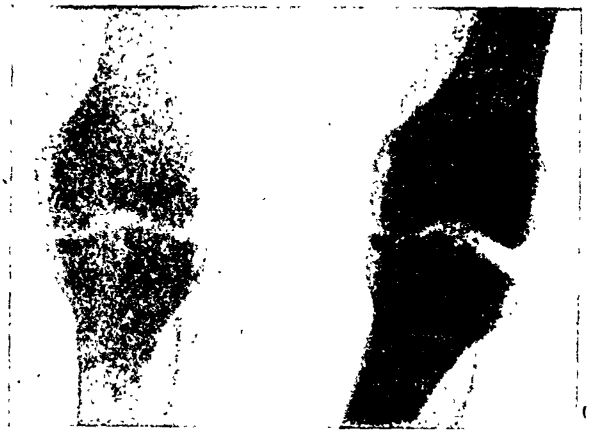

FIG. 5.—Radiogram showing laxity of knee-joint due to rupture of external lateral ligament.

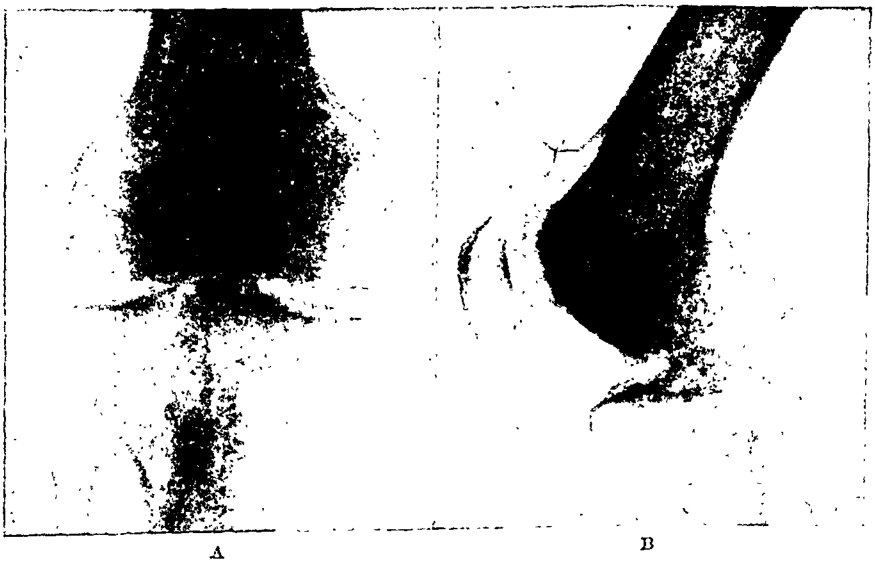

FIG. 6.—Radiograms showing loose body impacted in intercondylar notch; (A) front view, (B) lateral view. Removal necessary to allow extension of joint. (Author's case.)

Following a severe strain traumatic exostosis or ossification in the ligaments may occur as a result of new bone formation at the site of rupture. This will as a rule be demonstrated by radiograms. If the stability of the joint is good as a result of conservative treatment, they should be dealt with surgically only if they give rise to trouble. Cases of recurrent disability following strain of a lateral ligament may, however, occur in which the X ray reveals no injury to the bone—so that if tenderness definitely localised to the attachment of the ligament persists after appropriate conservative treatment, the question of exploration of the tender area should be considered. A lady, the wife of a doctor, and aged 28, stated that since severely twisting the knee three years previously she had been unable to take part in sports because of a severe pain referred to the inner side of the knee if it was subjected to strain. Examination revealed a definitely tender point over the inner condyle of the femur, and pain was referred to this point on forced abduction and external rotation. The X ray was negative. On exploring the tender area I found a tiny sharp spicule of bone with a bursa around it. Since removal of this spicule of bone she has had no recurrence of trouble in the knee.

Perhaps the next most common condition to simulate lesions of the semilunar cartilages is the presence of loose bodies in the joint. They may be due to a number of causes, including traumatic separation of a portion of the articular cartilage—separation of osteophytes, or osteochondritis of the internal condyle. The X rays will usually establish the diagnosis. The symptoms usually differ from the cartilage displacement in that the locking is very temporary, the body being nipped and immediately displaced from the position in which it obstructs movement, and the site of pain is variable. The history will also reveal that the knee has not always felt just as good as the other prior to the commencement of definite symptoms. Some limitation of extension of gradual onset may occur as a result of an accumulation of loose bodies in the posterior aspect of the joint, but where a sudden and persistent limitation of extension occurs it has in my experience always been due to a moderately large body becoming wedged in front of the attachments of the crucial ligaments. When it is in this position manipulation will fail to dislodge it, and operation is necessary for its removal. I show you the X rays of the last case on which I operated for this type of locking (Fig. 6, *a* and *b*). It is interesting in that it illustrates changes in the joint following a fracture of the patella 18 years ago. Lieutenant H. was shot down when flying in October, 1915. Seven months later he presented himself at Shepherd's Bush Hospital with a comminuted fracture of the upper part of the patella, with 2½ in. separation of the main fragments, so that voluntary extension of the leg was not possible. At operation the smaller fragments were removed, and continuity of the main fragments secured by wire suture. The wound broke down, the wire was removed, and he left hospital some months later wearing a knee cage, and gradually developing an increasing range of movement. I saw him again in October, 1933, when he told me that although he had never been able to flex the knee fully, he had played golf and tennis regularly without trouble until June of that year, when he began to feel something catching in the joint, which, apart from slight effusion and annoyance caused little disability. Fourteen days prior to my examination he reported that when going down stairs the knee jammed, and he had been unable to straighten it since. On examination one could feel lipping of the articular margins, and the movement of extension was blocked 30 degrees short of this position. The X ray revealed a loose body in the intercondylar notch, and also numerous marginal osteophytes, particularly round the patella. The body was exposed, and as a matter of interest it was noted that it could not be displaced by manipulation. Since its removal the joint has recovered its pre-operative range of movement.

Lesions of the Extensor Apparatus

Lesions of the extensor apparatus of the knee-joint may be diagnosed when although the patient is unable fully to extend the knee voluntarily, painless passive extension is possible. On palpation the point of tenderness will indicate the site of the lesion. The following lesions may occur: separation of the tibial tubercle, detachment of the ligament from the lower border of the patella, transverse fracture of the patella, or separation of the quadriceps tendon from the upper border of the patella. The site of lesion will depend on the relation of the patella to the condyles of the femur when the protective action of the quadriceps comes into play. As a result of the strong contraction of this muscle, considerable separation of the fragments may occur at the site of rupture, so that surgical treatment is usually necessary. These observations as to the site of lesion are based partly on experience of mobilisation of knee-joints in war surgery, but also on the fact that three consecutive cases of rupture of the quadriceps attachment to the patella occurred in gentlemen late in the evening, at a time when their cerebral control of muscle action might have been somewhat delayed. Perhaps earlier in the evening the protective action of the quadriceps might have been more prompt, and no lesion or perhaps fracture of the patella would occur. The contractile power of the quadriceps presents the real difficulty in maintaining apposition of the structures at and after operation. In cases of fracture of the patella wire sutures are not infrequently used, and we are apt to depend on suture by heavy chromised catgut or kangaroo tendon to maintain attachment of a ruptured quadriceps tendon to the upper border of the patella.

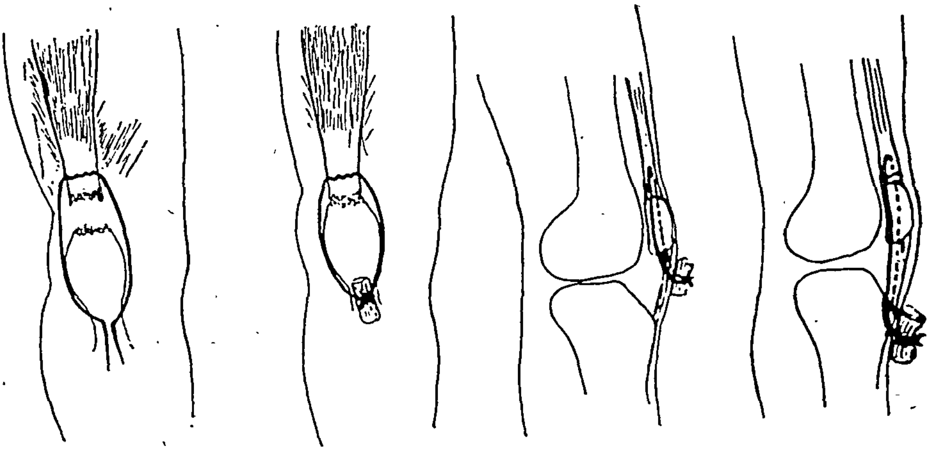

FIG. 7.—Diagram showing tension suture used in repair of rupture of the extensor apparatus.

In my experience these methods have been open to grave objections. We know that nature resents the presence of foreign, unabsorbable materials in the tissues, whether these are vaselin, metal screws, plates, or wires, and that sooner or later a local inflammation results, necessitating their removal. I will refer to one case which clearly demonstrates this. Just before our military hospital in Birmingham was closed a pensioner reported for treatment because of a discharging sinus in front of the patella. His record card showed that he had sustained a simple fracture of the patella, which had been treated by operation ten years previously. For nine years he had worked regularly, and the knee gave no trouble. Then local inflammation occurred, the operation scar broke down, and a sinus persisted. A radiograph was taken, but this did not show the presence of a wire or other foreign body. It was decided to excise the sinus, and during the operation we found a plaited band of silkworm gut sutures partly embedded in the bone. With the removal of these the wound healed. On several occasions in which I have used strong chromised catgut or kangaroo tendon, mild local inflammation with evacuation of portions of the suture material has occurred. I believe also that tight suturing at the site of lesion diminishes the blood-supply and delays repair of the tissues. I have found that these difficulties may be obviated by a simple expedient which removes the pull of the contractile power of the quadriceps from the suture line (Fig. 7). The accurate repair of the lesion can then be established by fine catgut sutures. The method we adopt is to pass a pliable phosphor-bronze wire in a sinuous course transversely through the quadriceps tendon. The ends, on separate needles, are passed down the lateral borders of the patella and emerge through the skin in close proximity either below the patella or at the level of the tibial tubercle. In most cases it is sufficient to tie this wire suture over a pad of gauze at the level of the lower border of the patella. Occasionally, when much tension is necessary, it is advisable to pass the wires in opposite directions through a hole drilled in the tubercle of the tibia, when they are drawn tight and tied over a pad of gauze which protects the skin from pressure. At the end of two to three weeks the wire is divided and easily withdrawn.

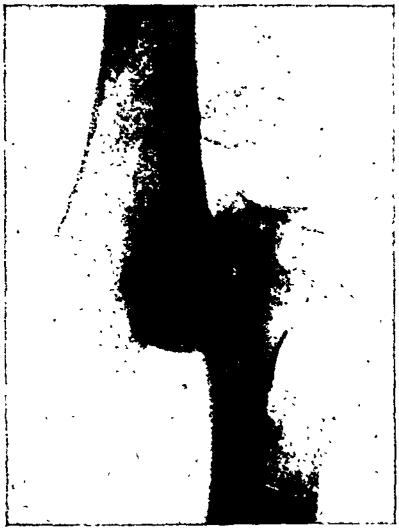

FIG. 8.—Case of complete dislocation of the knee treated by conservative means. Radiogram showing the injury.

Rupture of the Crucial Ligaments

Complete dislocation—One of the most severe disabilities following injury of the knee-joint is loss of antero-posterior stability of the joint following rupture of one or both of the crucial ligaments. These cases are usually associated with injury to the internal lateral ligament and one or both cartilages. The operation advised by Alwyn Smith and Hey Groves offers an ingenuous method of replacing these ligaments by fascial and tendon transplantation. My experience of the operation has been that stability of the joint was definitely increased, and that for several months it appeared to be almost a perfect success, but later examination always showed the presence of a degree of antero-posterior movement which did not justify the removal of splintage. I have always had the feeling that the removal of a troublesome meniscus was not an unimportant factor in the patient's satisfaction with the result obtained.

Apart from dealing with lesions of the cartilages or lateral ligaments if present, my practice is to treat lesions of the crucial ligaments on conservative lines. Where a fracture of the tibial spine blocks extension, this can usually be overcome by gradual splintage or manipulation, and although theoretically full extension may not be the ideal position for the treatment of these lesions, in practice it has given excellent results. In orthopædic surgery more than any other branch of the art, a knowledge of what nature can do is necessary to temper our judgment, and to assess the proper value of our procedures. This is well illustrated by a case of complete dislocation of the knee which came under my care last year (Fig. 8). I first saw him six weeks after his injury. The history of the case is: A workman, E. B., aged 40 years, sustained a complete dislocation of the knee, the femur being displaced backward on the tibia as a result of a heavy pipe falling on its lower end. Under general anæsthesia the dislocation was reduced, a pressure bandage applied, and the leg rested on a pillow, and steadied between sandbags. Five days later the effusion was aspirated, massage commenced, together with electrical treatment, and contractile exercises for the quadriceps. At the end of a fortnight limited active movements of the joint were encouraged. Four weeks after the accident he commenced to walk with a stick without splintage, and two weeks later he had 90 degrees controlled movement of the joint from extension, and could walk without limp or pain. The X rays show the dislocation, an injury which must have caused complete rupture of both crucial ligaments. The photographs taken ten weeks after the accident show no instability with the patient bearing his whole body-weight on the injured limb, with the knee in a position of flexion (Fig. 9, *a*, *b*, and *c*). To-day, 18 months after the accident, there is no clinical abnormality of the joint. Joseph Mitchell [9] has reported similar cases.

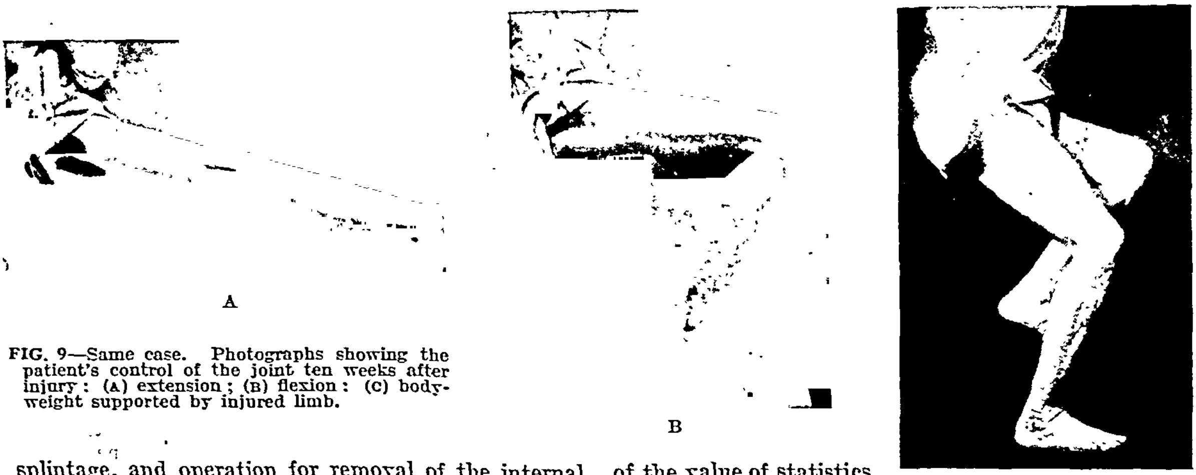
Traumatic Arthritis

We have dealt so far with injuries in which a definite pathological lesion can usually be demonstrated, but in reviewing a series of cases of injury of the knee-joint we all find a large number in which disability persists, although no definite lesion of the joint structures has occurred. This will include many in which movement remains limited as a result of a traumatic and/or toxic arthritis following the injury. We recognise that direct or indirect trauma of the shoulder-joint is not infrequently followed by a painful limitation of movement of the joint. This is more common in patients past middle life, and they usually have a toxic diathesis. Probably the main fact that saves them from operative treatment is that the X ray is negative, and that there are no intra-articular fibrocartilages in the shoulder-joint. In the case of the knee-joint, however, the possibility of a cartilage lesion makes the diagnosis more difficult, and I know I have many times in my earlier days removed normal cartilages as a result of faulty diagnosis. Fortunately the operation is helpful in that the convalescence ensures rest of the joint, which is one of the essential lines of treatment of the condition. The fact that after operation the patient usually still complains of pain in the joint on full extension, and does not make the usual quick recovery of movement, also draws our attention to the importance of investigation of a possible septic focus. With appropriate treatment of this, and the local joint condition, a complete recovery of function usually occurs. When you are dealing with a primary lesion of the knee-joint the history of injury may be such as to make cartilage displacement possible, and the persistent limitation of and pain on forcing full extension of the joint make this seem most probable. I have seen it in a girl of 26 in which the doctor reported to me he had reduced a dislocation of the knee six weeks previously, but extension was still limited. I manipulated the joint, but the pain of treatment in full extension necessitated removal of splintage, and operation for removal of the internal cartilage was advised. At operation the pink injected margin of the articular cartilage was noted, and removal of a normal internal semilunar cartilage did not allow painless extension of the joint. The possibility of this condition must always be borne in mind in dealing with limitation of extension following a primary injury of the knee-joint. Tenderness may appear to be more marked on the line of the internal cartilage, but if the articular margins of the condyles of the femur are also tender, and pain is present both on forcing flexion and extension our prognosis should be guarded. Operation should be advised only in cases in which the nature and severity of the injury suggest the probability of the complication of cartilage displacement. Manipulation during the period of inflammation is useless, but when pain and all local tenderness have gone, it may be utilised to establish a full range of movement.

Manipulative Surgery

The knee is perhaps second only to the spine as a field for the activities of the manipulative surgeon, but it is amazing to me how seldom we who deal constantly with joint injuries have occasion to employ it. It should always be utilised to ensure full extension of the knee when displacement of a cartilage is the probable cause of limitation of this movement, except in cases of recurrent displacement, when the diagnosis is clear. In these cases the patient should be advised to have the cartilage removed by operation, which is the only means of preventing recurrence of the trouble. I find that at least 90 per cent. of the professional footballers on whom I have operated have previously had their joints manipulated by a bone-setter. The majority of the cases which they cure are, however, cases of joint strain which have recovered from the usual reaction of a joint to trauma or mild arthritis, but the patient still complains of pain on certain movements. During the stage of active reaction forcing of movements can do nothing but harm, but there does come a time following injury at which forcing of movements, although painful at the moment, may be dramatically effective in its results. It will not, however, usually be necessary if other measures have been adopted to restore the fullest possible range of painless movement.

The volume of recent literature dealing with injuries of the knee-joint is a sure indication that the question of their diagnosis and treatment has not yet been standardised. This is probably due to the fact that the frequent association of injuries makes the presentation of the clinical picture and the assessment of the value of statistics difficult.



A B C

FIG. 9—Same case. Photographs showing the patient's control of the joint ten weeks after injury: (A) extension; (B) flexion: (C) body-weight supported by injured limb.

These observations on some of the common injuries of the knee-joint are offered so that we may by our discussion help to clarify some of the problems which we all meet.

I am much indebted to Mr. A. M. Hendry for his help in reviewing the cases, and to Dr. Brailsford for preparing the slides and photographs.

Summary

1. That damage to an intra-articular fibrocartilage occurs in almost 50 per cent. of severe injuries of the knee-joint. 2. That the posterior segment of the cartilage is most frequently the site of the primary injury. 3. That lesions of the external semilunar cartilage are relatively more frequent than published statistics would suggest. 4. That congenital abnormality of the external cartilage may frequently be diagnosed in childhood, and should be dealt with surgically. 5. That a loose body causing a sudden persistent irreducible limitation of extension is wedged in the intercondylar notch. 6. That in repair of lesions of the extensor apparatus muscle pull should be overcome by a removable suture. 7. That the results of operation for repair of rupture of the crucial ligaments are uncertain, and that a complete recovery of function may take place as a result of conservative treatment. 8. That while accurate diagnosis of an original injury may be difficult, the cause

of a recurrent lesion can usually be established as a result of a carefully taken history, together with clinical and X ray findings. 9. While conservative or manipulative treatment is successful in many cases, a surgical exploration of the joint will always be necessary for the cure of a large number. 10. In the surgical approach to the inner side of the knee, incisions which may divide the patellar branch of the internal saphenous nerve should be avoided.

THE RÔLE OF THE LIVER IN THE METABOLISM OF CARBOHYDRATE AND FAT *

By C. H. Best, M.D., D.Sc. Lond., F.R.C.P. Canada

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF TORONTO

III.—THE DEPOSITION OF LIVER FAT

In the first lecture of this series the evidence that the liver is an important site of formation of the ketone bodies was briefly reviewed. The rapid disappearance of these substances from the blood of diabetic animals after removal of the liver, their formation from long chain fatty acids with an even number of carbon atoms in the perfused liver, and the behaviour of these fatty acids when incubated with liver slices, furnish the main points which permit us to attribute to this tissue a special significance in the oxidation of fatty acids. I will not attempt to discuss this phase of the subject in detail or to review the evidence for the attractive hypothesis that fatty acids are desaturated in the liver. It appears at present that selective retention by the liver cells of the more unsaturated fatty acids may provide as satisfactory an explanation of the facts observed as does desaturation. Recent work indicates that the double bond may not always be the point of rupture of the fatty acid chain.

The excessive increase in the neutral fat of the liver, the so-called "fatty infiltration," and the change in the physical characteristics of the fat with more or less extensive damage to the liver cells, the so-called "fatty degeneration," are the most striking phenomena encountered in a superficial study of the rôle of the liver in the metabolism of fat. The multiplicity of conditions in experimental work and clinical studies with which excessive deposition of fat in the liver may be associated indicates either that these conditions produce some effect common to all of them or that one of the most easily disturbed properties of liver cells is their ability to deal with fat.

Little information is available on the effect of different fatty acids in the production of fatty livers. Miss Ridout and I found that certain saturated fats tended to produce greater deposition of liver fat than unsaturated mixtures. On the other hand, two fatty materials, butter and beef dripping, iodine numbers 32 and 40, varied greatly in this regard. Beef dripping was much more effective than butter. We soon realised, however, that among the significant factors the choline content of these mixtures must be considered, and that until this had been determined the effect of unsaturation or of the number of carbon atoms of the ingested fatty acids on the deposition of fat could not be decided. It is now known that the amount of depôt fat influences the extent of the deposition of fat in the liver during starvation (Mottram; Dible). A complete statement of the conditions which lead to these changes is unnecessary, but I may remind you that they are observed in the first stage of starvation, and are easily produced in the livers of young animals of many species by diets rich in fat. The amounts required to produce similar effects in adult animals of some species, the dog for example, are much greater. Prominent among the list of substances which may induce these fatty changes are cholesterol, alcohol, phloridzin, chloroform, phosphorus, carbon tetrachloride, and phenylhydrazine. Bacterial toxins may cause an unmasking of the liver fat and also an increase in the amount. Extensive fatty changes are, of course, characteristic of experimental and clinical diabetes in the absence of insulin. Pregnancy in rabbits may be accompanied by fatty changes (Mottram), but in the experience of Huntsman and MacLean in my laboratory these are seen much more frequently in rats. Pernicious anæmia, yellow fever, acute yellow atrophy, eclampsia, and poisoning with some of the chemicals listed above are among the many clinical conditions in which "fatty livers" are encountered.

The mechanism of production of these fatty changes is obscure, but it is fascinating to speculate, as Fischer and Hooker have done, that in many of these conditions the alkali reserve of the liver cells may be decreased. While there is no direct evidence for this hypothesis it is worthy of extensive investigation. Experiments in which ammonium chloride has been fed to rats have thus far provided no support (Huntsman). I will not attempt a comprehensive discussion of these fatty changes but will take the opportunity of presenting to you a series of results which, even if their physiological importance should prove to be slight, have served to attract to this fascinating field a new group of workers. This study of certain of the factors which control the deposition of liver fat is an outgrowth of the insulin investigation in Toronto and may be said to have its inception in the work of Allan, Bowie, Macleod, and Robinson,[1] who found it necessary to provide fresh pancreas in the diet of depancreatised dogs in order to enable the animals to live for more than five or six months under the prevailing experimental conditions. When pancreas was not provided the animals eventually died, and at autopsy presented very fatty livers as the outstanding—and in some cases the sole—abnormal feature. I think the story will be somewhat clearer if I state at this point that results have recently been obtained which suggest that some influence is affecting the liver cells of these diabetic animals which prevents them from performing their normal functions, before there is an obvious or even a detectable increase in fat.

The evidence for this statement is based upon study of liver tissue in several animals which were apparently in the same condition, in so far as rate of sugar production by the liver was concerned, as others in which abnormal amounts of liver fat were found. The usual history of the diabetic dogs is that after pancreatectomy they excrete large amounts of sugar on a fixed diet and dosage of insulin, but that the glycosuria becomes less and less, until little or no sugar is present in the daily urine samples. If a sample of liver is then obtained, the total fatty acid plus unsaponifiable fraction may not be abnormally high. Some animals may excrete little or no sugar on a low insulin dosage for several months without exhibiting this excessive deposition of liver fat.

---

* Three lectures delivered for the University of London at University College on Jan. 11th, 15th, and 18th.

This finding might easily have been overlooked for a much longer period of time if we had not adopted the practice of obtaining evidence by analysis of liver tissue obtained at biopsy rather than depending upon the insulin requirement, the excretion of sugar and bile-pigments, on the results of liver function tests and on the general health of the experimental animal, as indices of the state of the liver cells. This falling off in sugar excretion is not due to depletion of the glycogen reserves. Our attention has, of course, been focused on the anterior pituitary and this gland is being carefully examined in the hope that the histology may suggest the state of its activity under these conditions. Another possibility, which is difficult to eliminate, but for which we have obtained no evidence, is that a few islet cells have regenerated. The most likely explanation appears to be some change in the liver cells which proceeds and possibly predisposes them to the fatty changes.

In many of these animals large amounts of fat eventually accumulated in the liver. The diet which they received was low in calories—300 g. lean beef, 100 g. sucrose. It was found, as stated above, that the accumulation of liver fat in these diabetic dogs did not occur when fresh pancreas, 100 g. daily, was provided.

Macleod and his co-workers naturally considered the possibility that pancreatic lipase might be concerned in this effect, and this feeling was perhaps strengthened when the fatty livers were not observed in animals which received a commercial lipase preparation. This material is usually prepared by "defatting" the minced glands with acetone, a procedure which does not remove more than a small amount of the phospholipoid. Prof. Macleod was primarily interested in the metabolism of carbohydrate in these diabetic dogs but he provided facilities for Hershey to continue the investigation of these fatty changes. The problem was to determine the constituent of the pancreas responsible for the effect. The great difficulty in this very tedious type of experimentation is that the dogs exhibit vitamin deficiencies and it is usually not feasible to provide highly purified fractions in the large amounts necessary. The possibility that the phospholipoid fraction might be exerting an effect on liver fat was made prominent by Leathes' emphasis on the probable significance of these substances in fat metabolism. Since it was not feasible to prepare this material from pancreas, a commercial phospholipoid fraction from egg yolk was first investigated by Hershey.[2] These experiments were continued in the Department of Physiology from 1926 to 1932 and the results (Hershey and Soskin; Best and Hershey) eventually convinced us that the phospholipoid fraction from egg yolk not only exerted an effect comparable to that of the fresh pancreas, as the original findings had indicated, but that the action of the former material was not due to the vitamins which it contained. In subsequent experiments upon these diabetic dogs, vitamins (Bemax, activated ergosterol, and tomato juice) have been provided.

The onset of fatty changes in the liver, apparently similar to those previously studied, can be produced relatively rapidly in most of these animals by adding fat to the diet. We studied many dogs before we encountered one which would retain large amounts of ingested fat without exhibiting these characteristic changes in the liver cells. An animal which is remarkably resistant to these effects of a diet rich in fat has been encountered recently. Experiments upon diabetic dogs are very tedious, and in the search for more satisfactory test objects for these effects produced by the phospholipoid fraction we found that normal white rats could be used (Best, Hershey, and Huntsman). Some component of this material prevents the deposition of fat in the liver, which takes place when rats weighing between 150 g. and 250 g. are placed on a diet containing 40 per cent. beef suet. In the search for the active component of the phospholipoid Miss Huntsman and I found that this was choline, and we have had occasion to use choline to prevent deposition of fat in the livers of rats in a large number of experiments.

The chemical results of a certain group of these experiments are summarised in Table I. The figures in this table show that the livers of animals fed upon a stock diet with 40 per cent. added fat contain on the average 14·2 per cent. fatty acid plus unsaponifiable material, while those which have received what may be considered an adequate dose of choline have an average value of 4·5 per cent. It is satisfactorily established, therefore, that choline possesses the property of preventing deposition of fat in the rat's liver under the conditions of these experiments.

TABLE I

Stock diet plus fat (fat 40 per cent. of total food) for 21 days.

No. of rats.	Choline daily. mg.	Fatty acids of liver per cent.
203	—	14·2
109	75	4·5

To make sure that this effect of choline in rats was not a quite different matter from the action of the phospholipoid fraction in diabetic dogs, Ferguson, Hershey, and I[3] investigated the effects of choline in these latter animals.

In some dogs the sugar excretion is apparently greatly increased by choline administration, and there is reason to believe that deposition of fat in the livers of these animals, or perhaps better, the development of the condition which leads to decreased sugar excretion, is prevented by choline. It is always more satisfactory to demonstrate the change produced by a substance in an individual animal and not to rely upon the differences exhibited by a series of control and test animals. This is particularly important in these experiments with diabetic dogs because it is seldom possible to use more than a limited number. Evidence based upon direct examination of liver tissue (Best, Ferguson, and Hershey) in an individual animal has been presented which appears to demonstrate that choline is effective in decreasing the fat content of the liver. In this particular animal chemical analyses made on a section of liver secured on a certain date revealed the presence of 20·6 per cent. fatty acid. The diet and insulin dosage were maintained at a constant level. Choline was provided and one month later another section of liver was secured. The content of fatty acid was 6·7 per cent.

This result appears to provide satisfactory evidence that choline is effective under certain conditions in decreasing the fat content in the liver of a diabetic dog and suggests that the action of choline is curative as well as prophylactic. It is reassuring that Miss Huntsman and I have been able to demonstrate what appears to be a similar phenomenon in rats. It has been possible to show that choline not only prevents the accumulation, but also causes the disappearance of excess fat from the livers of rats.

In the first curative experiment the control animals with fatty livers were allowed to remain on the diet rich in fat. The test animals received choline. At the end of 21 days the test animals had a normal content of liver fat, while the livers of the controls were uniformly fatty. In the second experiment the control animals received, instead of the diet rich in fat, the stock diet composed of mixed grains. The test animals received the same amount of the grain diet and, in addition, choline. The figures show that the fat disappeared more rapidly from the livers of those animals which received the added choline.

More recently Miss Huntsman and I have conducted a different experiment.

Fatty livers were produced in a large group of rats by feeding fat in the customary manner. The control animals were then placed on a diet containing 80 per cent. sucrose and 20 per cent. "fat-free" casein (British Drug Houses). The 2 g. of casein which each rat received daily contained 6 mg. of fatty acid. The test animals received the same diet as the controls, but in addition 70 mg. of choline per day. The decrease in the fat content of the livers of the test animals was very rapid, but the fat content of the livers of the control animals remained at quite a high level. The interesting point arises as to whether or not the difference in the fat content of the two groups of control animals is related to the choline content of the diet which they receive. Analyses for choline made for us by Mr. Fletcher indicate that the animals on the grain diet were receiving 10 mg. of choline daily, while the animals on the sucrose and casein ration received only approximately 1 mg. of choline daily. The minimum effective amount of choline has not yet been determined accurately, since in the past we have not paid sufficient attention to the choline content of our stock diets. It appears very likely, however, from the figures which we have available, that 10 mg. per day is an effective, although not an optimal, dose for a rat under these conditions.

These results, together with those which Miss Ridout and I had obtained earlier, indicate that future experiments on diabetic dogs and normal rats should be conducted with the control animals on a choline free diet. These experiments are interesting from two other points of view, and I may have occasion to refer to them again. You will remember that Rosenfeld[4] has shown that diets high in carbohydrate may prevent the development of fatty livers in phloridzin poisoning. It is apparent from our results that choline is much more effective than a diet containing 80 per cent. sucrose and 20 per cent. casein in the elimination of the deposits of fat from the livers of these white rats. The second point to which I would like to call your attention is that these results exclude the possibility that the principal effect of choline is to decrease the rate of absorption of fat from the intestine. I will discuss this matter again later. One other result may be briefly mentioned. Miss Huntsman and I planned another experiment to determine the relative merits of a very high carbohydrate diet and of choline in the cure of these fatty changes.

Rats with fatty livers were placed on a diet composed exclusively of sucrose. One-half of the animals received choline. The livers of the sucrose fed animals became steadily more fatty until at the end of twelve days an average value of 24 per cent. was reached. The animals receiving choline responded in much the usual way and the average fat content after twelve days was approximately 5 per cent.

This unexpected increase in liver fat when the diet contains no choline provides us with further problems.

Another point which may be mentioned here is that Miss Ridout and I found, in confirmation of previous workers, that the addition of cholesterol to the diet of rats or rabbits produces very intensive fatty infiltration and degeneration of the liver. It has been shown that this change may be prevented in rats if sufficient choline is added to the diet. Much more is required in these experiments than in those in which fatty changes were produced by feeding fat. This point has not received sufficient attention from other investigators, who have stated that their results were not completely in harmony with ours. While we have not as yet had an opportunity of investigating many substances similar in chemical structure to choline, it has been shown that betaine is effective in preventing the development of fatty livers in rats which are receiving a diet rich in fat (Table II.) or in cholesterol.

Choline and the Fatty Liver of Starvation

Miss Huntsman has had the opportunity of securing large numbers of figures on the increase in the fat content of the rat's liver during starvation. If choline is given only during the period of starvation an effect is not clearly demonstrable, but if it is added to the stock diet for some weeks previously and during the period of starvation the accumulation of liver fat does not take place. These results suggest that some of the choline may be stored or that it is possible to affect the mechanism which controls the deposition of liver fat by the previous administration of choline. We have not as yet found it possible, however, to detect any difference in the amount of fat deposition in the livers of rats when they are placed on a diet rich in fat after they have received for a period of three weeks large amounts of choline in addition to the stock diet. The livers of the animals receiving the choline are quite as fatty as those in the control groups. It is rather difficult without using very large numbers of rats to demonstrate a definite deposition of fat under these conditions before the animals have been on this diet for six or seven days. At the end of this interval there is no difference in the fat content in the livers of the two groups. There may be a definite difference during the first few days. One would not expect that large amounts of choline could be stored.

It may be pointed out here that the total choline in a tissue can be quite satisfactorily estimated by freeing the bound choline by acid hydrolysis in alcoholic solution. The alcohol and much of the acid are removed by distillation. The choline may then be acetylated and the acetylcholine assayed against standard acetylcholine on the isolated rabbit's intestine. Fletcher will report in due course the results of choline estimations on the various tissues of rats, some of which have received choline in large amounts. The question of whether any choline exists in a free state in the body has perhaps not been settled, though the recent report of Strack, Neubaur, and Geissendörfer[5] holds considerable interest. Their results and those which have been obtained in my department suggest that there is very little free choline. Fletcher and Solandt find that beef pancreas contains approximately 200 mg. per cent. of choline. The diabetic dogs studied by Allan et al. received approximately grs. 100 of pancreas per day. If these animals had received grs. 500 or 600 of beef muscle, as many diabetic dogs do, the choline content might have been sufficient to postpone the onset of the fatty changes. On the other hand, the data we have at present available do not suggest that 200 mg., the amount available in the pancreas, would be an effective curative dose of choline. It might well be sufficient to postpone the onset of the fatty changes. There is a possibility that betaine and other substances closely related to choline may also be present in appreciable amounts in this tissue. When studies of choline content of tissues are made precautions should be taken to prevent enzymatic loss of the active material (Bernheim; Fletcher).

The Mechanism of Action of Choline

If we knew more about production of fatty livers by such agents as phosphorus or chloroform, and so forth, a lead to the mode of action of choline and betaine might be supplied. The most obvious way in which choline might affect liver fat would be to decrease the amount absorbed. However, we have never been able to obtain any evidence that fat excretion is increased by choline. Furthermore, there is no difference in the change of weight in animals with and without choline. Miss Huntsman, Solandt, and I were never able to find any change in body fat in the animals which received choline. The experiments with which Miss Ridout, Prof. Channon, and I have recently been occupied provide satisfactory evidence that there is no appreciable change in the amount or character of the depôt fat attributable to choline. The possibility still exists, however, that although the amount of fat absorbed was not decreased the rate might be affected. It is possible that the rapid absorption of fat would produce fatty livers while the slower absorption might not. Miss Huntsman and I have demonstrated that it is not necessary for the choline to be administered with the fat, and also that choline administered subcutaneously definitely decreases the deposition of liver fat. If the choline hydrochloride is given in the morning and the rat is fed once a day in the late afternoon, the effect on liver fat is easily demonstrable. None of these experimental results eliminate the possibility that choline affects the permeability of the intestine to fat. As I have mentioned previously, we have not as yet been able to secure a reliable method by which the effect of choline on the absorption of fat can be determined. Work on fat tolerance curves has been abandoned, and up to the present the amount of fat which will be absorbed in the intestine of the rat in a certain time cannot be predicted with any certainty. The results which I have quoted previously, however, show that absorption cannot be an important factor. It will be remembered that in one of the experiments the animals were placed on a diet containing very little fat, about 6 mg. per day per rat. If choline had completely prevented the absorption of fat throughout the whole experiment the maximum loss to the liver would have been 60 mg. Since the liver of the control rats contained on the average 10 per cent. fatty acid at the end of the experiment and would weigh about 7 g., each would contain approximately 700 mg. fatty acid. The livers of the test rats contained 2·8 per cent. fatty acid and would weigh about 5 g.—i.e., each would contain approximately 140 mg. If the effect had been to prevent absorption, the 60 mg. present in the diet would produce relatively little effect in view of the fact that the liver has lost approximately 560 mg. Evidence pointing in this same direction is obtainable in the experiments on starved rats. It appears justifiable, therefore, to conclude that the chief action of choline is not on the absorption of fat.

Another possibility is, of course, that the oxidation of fat in the liver is increased. Miss Ridout has thus far been unable to obtain any evidence of increased oxygen uptake in rats which have received choline, but this result throws no light on what may be happening in the liver cells. The situation at the moment is, therefore, that this easily demonstrable action on liver fat is the only established effect of choline on fat metabolism.

One will hesitate a long time before concluding that this is in reality the only action of choline, but a study of the recent data in which Miss Ridout, Prof. Channon, and I are greatly interested, also focuses attention on the liver. These data are worth considerable study, and will be published in detail in due course. With the permission of my collaborators, I will review very briefly some of our findings and deductions. When fat is provided in the diet of white rats there is an accumulation of neutral fat in the liver. An increase in neutral fat can also be produced by cholesterol feeding, and under these circumstances there is also an increase in cholesterol ester and a very slight rise in free cholesterol. The main, and perhaps the initial, effect of choline is on the neutral fat of the liver, which is reduced to very low levels if adequate amounts of the base are provided. In the cholesterol-fed animals there is also a very definite decrease in the cholesterol ester, while the free sterol is practically unchanged. Choline has apparently very little effect on the phosphatide fraction. The improvement in liver function, which in some cases follows the administration of choline to diabetic dogs, may in part be due to elimination of the excess of neutral fat from the liver cells. The amount of fat which disappears from the liver is, after all, very small, and it is not surprising that it should escape detection if it is oxidised or carried to other tissues.

The deposition of fat in the liver is due either to the fact that excess is being presented to it, that the rate of oxidation or the retention of fat by the liver cells is changed, or that the factors which normally take fat away from the liver are not operating with sufficient speed. There is no increase in blood fatty acid when the liver becomes fatty in these diabetic dogs. The effect of choline on blood fat needs further study but we have no lead in this direction as yet. One of the most important possibilities is that choline stimulates the liver cells to oxidise fatty acids. Quastel's recent report suggests that the liver slice technique may permit the investigation of this problem in the Warburg apparatus.

There is another possibility to be considered. Early in this lecture I referred to the finding that the diabetic dogs lose some of their ability to produce sugar before there is any accumulation of fat in the liver. Miss Huntsman and I are now studying the effect of choline on sugar excretion under these conditions. If positive results are obtained the possibility will have to be considered that the action of choline on liver fat is secondary to one on sugar production.

The results of these researches have, I believe, provided us with new tools by the intelligent and energetic use of which our knowledge of fat metabolism may be augmented. Liver fat may be decreased by prolonged starvation, by thyroid feeding, or by insulin administration. We are not likely to under-estimate the significance of insulin in this connexion, but in diabetic dogs with a constant and apparently adequate amount of insulin and in normal rats receiving a diet rich in carbohydrate, which stimulates the liberation of insulin, choline exerts rather dramatic effects on liver fat.

It is a pleasure to acknowledge my indebtedness to my colleagues, whose names appear in the text, for their most helpful interest in these lectures.

A NEW TECHNIQUE FOR THE SELF-ADMINISTRATION OF GAS-AIR ANALGESIA IN LABOUR

By R. J. Minnitt, M.D. Liverp.

HON. ANÆSTHETIST, ROYAL INFIRMARY, DAVID LEWIS NORTHERN HOSPITAL, AND LIVERPOOL MATERNITY HOSPITAL, LIVERPOOL; HON. LECTURER IN ANÆSTHETICS, UNIVERSITY OF LIVERPOOL

Some analgesic for the sufferings of parturient women has been sought for a long time by those who sympathise with them. While gas-and-oxygen anæsthesia has been a satisfactory solution to the problem, the cost of the equipment and the necessary supervision by a medical man make it unavailable for the large majority of patients in labour. There appears, however, to be no question that the use of nitrous oxide should be developed. A method has therefore been evolved to combine this gas with a definite proportion of air, so that the constant mixture employed would produce analgesia without loss of consciousness.

The apparatus devised for this purpose was an adaptation of a McKesson oxygen therapy apparatus, and consists of a reduced pressure regulator, combined with a small rubber bag enclosed in a metal drum, so arranged that an automatic valve prevents the flow of gas when the patient does not inhale. The outlet of the machine is divided into two channels, one for the passage of gas and the other for air, admitted in a constant amount making a mixture of approximately 35 per cent. nitrous oxide in air. On the face-piece is fitted a spring finger release, which is pressed down during inhalation, but allows full air (thereby throwing the machine out of action) if the analgesia becomes deep enough to weaken the force used, or at the will of the patient. The expiratory valve is in the face-piece—non-adjustable, a spring allowing it to rise with expiration.

There are two models made, one in a carrying case as a portable model (Fig. 1) (overall size 12 in. × 8 in. × 18 in.; weight about 15 lb. without cylinders), and the other on an aluminium stand for hospital use (Fig. 2). The amount of gas consumed is on the average 35 to 40 gallons per hour; this depends on the frequency of pains and depth of breathing.

As the analgesia is self-administered the coöperation of the patient is essential. The important point is that at all times when inhaling the mixture from the machine the face-piece must fit in an air-tight manner.

Scientific work has been done in the Liverpool Maternity Hospital to show that there is no danger to mother or child by the use of the analgesia. Electrocardiograms were taken of a series of patients immediately before and at the end of the administration, and again a day or two later. Dr. Leslie Cunningham, Medical Officer in Charge of the Electrocardiograph Department of the David Lewis Northern Hospital, Liverpool, kindly reported upon these, and stated that they did not appear to be influenced to any significant extent as a result of the patients' experience. The alteration in the mother's pulse and the fœtal heart rates, estimated at approximately equal intervals during analgesia, were within normal limits.

A biochemical study was made of blood taken from a maternal vein and the umbilical cord in a number of patients immediately after delivery, with and without analgesia, and conclusions were drawn that although the administration of gas and air reduced the oxygen content of the mother's blood, that of the umbilical cord did not show any marked alteration.

As far as could be ascertained from observatio made on 81 primigravidæ and 47 multigravid making use of the analgesia for varying tim including delivery, the average length of the seco stage was within normal limits.

The apparatus has been in constant use, both the Liverpool Maternity Hospital and the Wellhou Hospital, Barnet, Herts, since the middle of Octob last, and over 300 cases have had the benefit of t analgesia. In the former of these hospitals the meth of the administration has been supervised by D Hilda Garry, under my direction, a grant having be given to the hospital by the National Birthday Tru Fund. In the latter Dr. John Elam, of Barne enthusiastically organised the inauguration of t new technique, under the supervision of Dr. H. Rolar Segar, the Medical Superintendent. Except in a fe cases which were found unsuited for this form analgesia, the relief from pain and distress w uniformly very good, both during the second sta and at the delivery. The failures, which did not com to more than 9 per cent. of all the cases observe were due to the following causes :

(1) Non-coöperation of the patient.

(2) Dislike of inhaling anything which migl produce unconsciousness, there being some difficult in persuading this type of patient that this would n happen.

(3) Hysterical conditions, which prevented th proper control of the method.

(4) A tardy administration, which meant tha education of the patient in the proper use of th apparatus was not possible before the birth of th child. The earlier the administration is commence the greater is the relief, as there is more time fo acquiring coöperation.

From my personal observation I feel that this ne

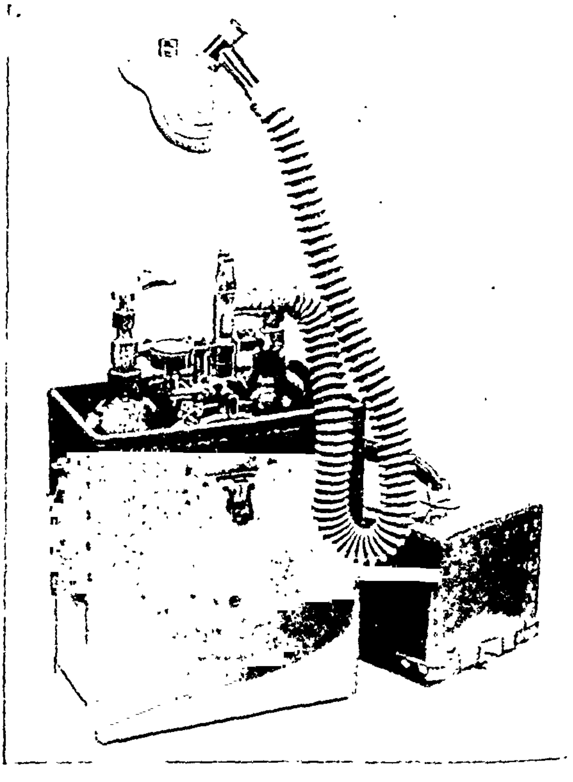

FIG. 1.—Portable model.

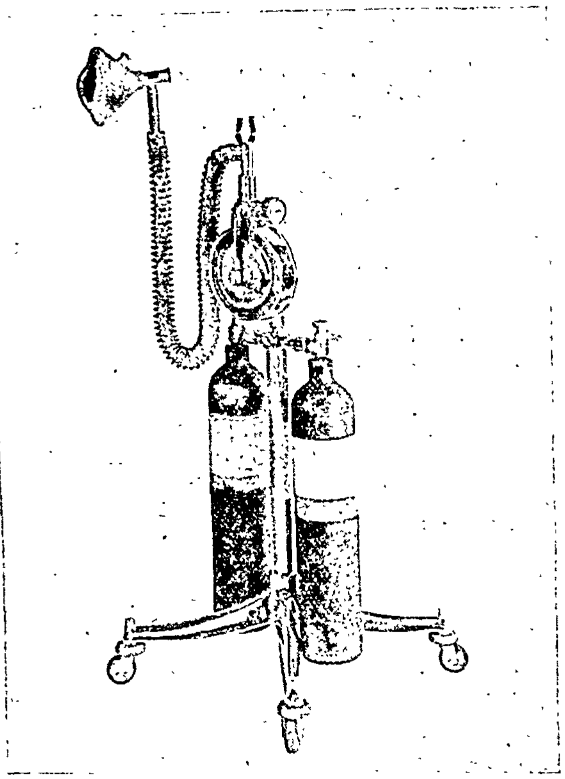

FIG. 2.—Hospital model.

technique has the following advantages. First, there is analgesia, which I define as insensibility to pain without loss of consciousness, so that the patient is able to understand and carry out any instructions given. Secondly, the apparatus is under her personal control, which permits the general practitioner or midwife to carry on the obstetric work without interference. Thirdly, the well-being of the patient both during labour and afterwards is conspicuous. It should be realised, however, that the apparatus was only designed for use in normal labour, and therefore is not applicable for such procedures as version, the application of forceps, or any extensive repair of the perineum. Anything of this kind carried out under analgesia, and not anæsthesia, might give rise to grave symptoms of shock.

As a general rule cyanosis should not appear during administration, although when the patient is holding her breath owing to bearing down slight blueness may be observed. As cyanosis is one of the signs of serious heart or lung disease, any depth of this should raise suspicion and the cause should be sought.

I can see no reason why an organised scheme should not be developed for the use of the method in domiciliary work (for patients attended by midwives) and I look forward to the day when the authorities will coöperate with the public in this enterprise.

Messrs. A. Charles King Ltd., London, are the manufacturers of the apparatus, which is known as the Minnitt gas-air analgesia apparatus.

UNIVERSITY OF LONDON.—It is announced that the Kent County Council have decided to make a grant of £40,000, payable over ten years, towards the cost of erecting new university buildings on the Bloomsbury site. The Worshipful Company of Butchers have also made a grant towards the ceremonial hall to be built on the site.

VITAMIN C IN THE HUMAN PITUITARY

By J. Gough, M.D. Wales

LECTURER IN PATHOLOGY IN THE WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF

AMONG the methods which have been devised for the detection of ascorbic acid (vitamin C) is the histochemical test of Szent-Györgyi.[1] This depends on the strong reducing properties of ascorbic acid, and when tissues rich in this substance are brought into contact with a dilute solution (0·4 per cent.) of silver nitrate for 15 minutes (in the dark) they become blackened from deposit of reduced silver. In animal tissues Szent-Györgyi found the strongest reaction to be obtained in the adrenal cortex, whilst in certain other tissues, such as brain, liver, and muscle, the reaction was practically negative, and he therefore concluded that the adrenal is specifically concerned with ascorbic acid. Later, Gough and Zilva [2] found that the anterior lobe of the pituitary in certain species—e.g., man, ox, and dog—yielded a stronger Szent-Györgyi reaction than the adrenal, and also that the corpus luteum in the dog was relatively strongly reacting. Further, they found by biological assay that the antiscorbutic potency of the anterior lobe of the ox pituitary was about twice as great as that of the adrenal. The pituitary, in the ox at least, appears to be the richest of the known vitamin-C containing tissues, and seems indeed to be as rich as any of the well-recognised natural sources of the substance, such as mango (Perry and Zilva [3]) and paprica (Svirbely and Szent-Györgyi [4]). Regarding the corpus luteum, Huszác [5] has shown by biological assay that this tissue in the pig contains as much vitamin C as the adrenal. Thus the three tissues which are already known to give a strong reaction with the silver nitrate test have been shown by other methods to be rich in the vitamin.

THE HUMAN PITUITARY

Applying the silver nitrate test to material from 42 hospital autopsies, Gough and Zilva found that the pituitary in man practically invariably stained darker than the adrenal, but they also noted that there was a considerable variation in the intensity of the reaction in different individuals. A series of 100 cases have now been examined, and the observation has been made that the intensity of the reaction in the pituitary runs roughly parallel with the state of nutrition of the body, as judged by the presence or absence of emaciation. On the whole a poor reaction occurs in persons who have suffered prolonged illness and are obviously emaciated, whilst a strong reaction is usually seen in those who appear to have suffered no appreciable disturbance of general body nutrition as a result of the fatal illness.

INTENSITY OF THE REACTION IN RELATION TO DISEASE

The Szent-Györgyi silver reaction was applied to 100 consecutive post-mortem cases of death from various diseases, and the cases were investigated and classified according to the intensity of the reaction into the following four groups—viz., strong, moderate, slight, and negative reactions.

Strong reaction (38 cases).—General nourishment of the body appeared approximately normal in 34. There was obvious wasting in only 4, and in none of them was this severe. The majority of the cases were of rapidly fatal illnesses. Of the 4 which showed wasting 3 were children 2–5 years of age dying of septic meningitis, pyonephrosis, and strangulation of the intestine respectively. The fourth was a woman of 36 years dying of cystitis one month after parturition. Of the remaining 34 cases—i.e., those in which nourishment was normal—17 were of illnesses lasting less than seven days, including 11 of acute infection (septicæmia, pneumonia, and meningitis), 2 of post-partum pulmonary embolism, 2 of obstructed labour, 1 of strangulated intestine, and 1 of ruptured basilar aneurysm. Seventeen cases were of longer illness; but of these 4 were ambulatory cases of papilloma of larynx, fibroid uterus, meningioma, and glioma respectively, in which death followed within 24 hours of surgical operation. These were virtually short illnesses. The remaining cases were: 3 of cerebral abscess, 2 of gummatous meningitis, 2 of leukæmia, and 1 each of tuberculous pericarditis, acute myelitis, aortic aneurysm, gastric ulcer, pseudohypertrophic muscular palsy, and carcinoma of the colon. In the last-mentioned case there was no apparent wasting and the first symptoms, due to acute intestinal obstruction, occurred ten days before death.

Thus although the cases giving a strong reaction were of a miscellaneous nature, they did not include a single case of long-standing disease with severe emaciation.

Moderate reaction (25 cases).—General nourishment of the body appeared normal in 16. There was moderate wasting in 8 and severe emaciation in 1 (tabes dorsalis) case. The cases of moderate wasting were: 2 of carcinoma of stomach, 1 of carcinoma of bladder, 1 of carcinoma of adrenals, 2 of leukæmia, 1 of miliary tuberculosis, and 1 of pericarditis. Those of normal nourishment were 9 of acute infection (septicæmia, meningitis, pneumonia), 4 of chronic cystitis, and 1 each of cholecystitis, pericarditis, and cerebral softening. It is to be noted that the cases of carcinoma of stomach showed little wasting, and both died within a few days of surgical removal of the tumour.

Slight reaction (26 cases).—Thirteen showed severe wasting, 9 showed moderate wasting, and only 4 appeared of normal nourishment. The cases of normal nourishment were cerebral softening, strangulated hernia, papilloma of bladder, and infantile convulsions. The cases of moderate emaciation were carcinoma of lung, glioma, empyema, chronic nephritis, congenital hydrocephalus, 2 of cystitis, and 2 of pernicious anæmia. The cases of extreme emaciation were carcinoma of lung, œsophagus, and pancreas respectively, malignant melanoma, sarcoma of jaw, Hodgkin's disease, obstructive jaundice, hyperemesis gravidarum, stenosis of œsophagus, 2 cases of gastric ulcer, and 1 of abscess of lung.

Nearly all the cases giving a slight reaction were thus of long-standing disease, and most of them showed emaciation.

Negative reaction (11 cases).—Eight showed severe emaciation and 2 moderate emaciation. In only 1 case was the general nourishment normal. All the cases were of illness longer than three months' duration. The case in which nourishment was normal was of carcinoma of the colon in a man of 75. The cases of moderate emaciation were syphilitic pneumonia and carcinoma of the tongue. The cases of extreme emaciation were 2 carcinoma of the stomach, 1 of œsophagus, 1 of lung, Hodgkin's disease, tuberculous peritonitis, pyelonephritis, and chronic ethmoiditis with meningitis.

In the 100 cases generally it will be seen that those in the first two groups are largely made up of deaths from short illnesses, while those which gave slight and negative reactions, on the other hand, are made up mainly of deaths from long-standing wasting diseases.

In order to ascertain as far as possible the state of the pituitary in the healthy individual, 7 cases of persons dying of rapidly fatal injury have been examined. Five of these gave a strong reaction (ages 16, 20, 21, 33, and 35 years), and two gave a moderate reaction (ages 63 and 67 years). The first-mentioned degree may thus be tentatively accepted as usual in younger persons, and the moderate degree in those over 60, and throughout the whole series it was noted that the reaction tended to be stronger in the young and middle-aged than in the aged. Strong reactions have been found in individuals of ages ranging from a few months to 60 years. It is interesting to note, however, that in the newly born the reaction was only of moderate intensity. (During the
course of this investigation four cases of neona
death were examined. These are not included in t
cases dealt with above.) There was no obvi
seasonal variation in the intensity of the reaction, a
strong reactions were obtained as frequently in t
winter as in the summer months. In this connexi
however, it may be pointed out that the temperat
at which the reaction is carried out must be st
dardised, as it has been found that at low temperat
the reaction is retarded. In the present work t
tests were carried out at normal room temperatu
The time at which the autopsy was carried out af
death did not appear materially to affect the intens
of the reaction, provided that it was not greater th
60 hours. All the bodies used in this investigat
had, however, been kept in a refrigerator.

DISCUSSION

In guinea-pigs, withholding of vitamin C from t
diet depletes the content normally present in t
adrenal (Svirbely [6]; Svirbely and Szent-Györgyi
and causes a diminution of the silver reaction (Mo
and Ray [7]; Siehrs and Miller [8]). That the failure
the human pituitary to give the reaction in cert
cases is due to a diminished content of the vitan
would seem to be a natural conclusion. Harris a
Ray,[9] however, have cast doubt on the reliability
a negative silver reaction as an index of the abse
of vitamin C. They base their views chiefly on t
fact that in the ox the adrenal medulla, which conta
a large amount of vitamin C, fails to give the reacti
They, and Huszác,[10] have suggested that in t
tissue there is a substance which inhibits the sil
reaction, and Huszác has shown that if the tissue
first treated with lead acetate the reaction can
satisfactorily obtained. I have ascertained that
negative reactions in the human pituitary are not d
to the same reason, for they remain negative e
after the application of Huszác's modified test. Y
since it has not been found possible to carry
biological assay on the human material, it see
unjustifiable to conclude definitely that the negat
reactions in the human pituitary are due to abse
of the vitamin. It is significant, however, that
healthy people dying as a result of accident or
those dying of acute disease the reactions were stron
positive, while in those dying of long-standing wast
diseases, especially when diet had been grea
restricted, the reactions were slight or negative. T
although the reaction was comparatively weak
most cases of malignant tumour, it was weakest
those cases of carcinoma of the alimentary ca
where emaciation was most severe. Again,
pituitaries from two cases of gastric ulcer where d
had been restricted showed only a slight reacti
while in another where diet had been normal a
death due to sudden hæmorrhage there was a stron
positive reaction. Perhaps the most significant c
was that of a child aged five months which had b
fed wholly on condensed milk. It developed sev
rickets and died of convulsions. It did not show a
signs of scurvy, but the Szent-Györgyi test
vitamin C gave only a feeble reaction in contrast to
intense one which was found in breast-fed infa
dying at that age. It thus seems possible to conn
the weak reactions with disturbance of food inta
Whether associated emaciation *per se* has a
influence, it has not been possible to determine.

In conclusion it may be stated that Vogt [11] h
found great diminution in the vitamin-A content
the pituitary in precisely those conditions which g
a poor silver reaction for vitamin C—namely, chro
wasting diseases.

SUMMARY

The Szent-Györgyi test for ascorbic acid (vitamin C) when applied to 100 human pituitaries obtained at autopsies showed: (1) that the reaction in the anterior lobe was intense in young and middle-aged individuals in whom general body nourishment appeared normal; (2) that the reaction was slight or negative in individuals who had died of long-standing disease with severe emaciation; (3) that the reaction was less intense in the aged than in younger subjects.

HYDATID DISEASE OF THE LUNG

WITH A CASE REPORT

BY R. G. PROSSER EVANS, M.R.C.S. Eng.

ASSISTANT TUBERCULOSIS PHYSICIAN, KING EDWARD VII. WELSH NATIONAL MEMORIAL ASSOCIATION, SWANSEA

ALTHOUGH hydatid disease is not rare in this country—contrary to the views often expressed by both physicians and surgeons—it may fairly be described as regional. For the past three years there have been admitted to the General Hospital, on an average, three cases each year from the Swansea district. These cases were mostly hepatic cysts. Human infection is usually due to eating unboiled vegetables soiled by the excreta of dogs or contaminated by flies (watercress is noted to be a frequent agent in the Swansea area). The swallowed ova develop into embryos which penetrate the wall of the bowel and are carried in the portal vein to the liver and thence to other parts of the body.

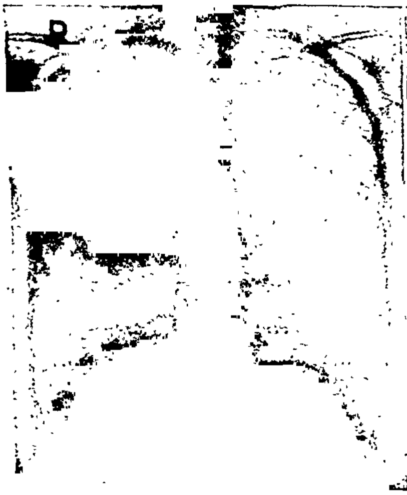

FIG. 1.—Radiogram taken three months after initial clinical examination.

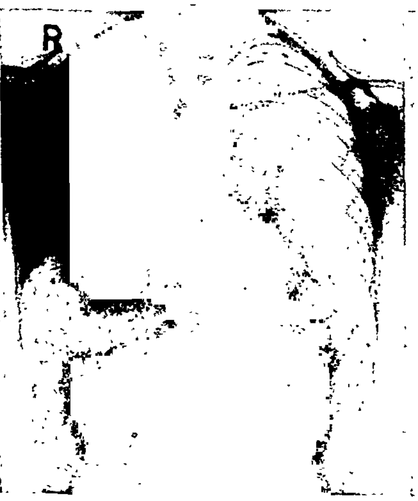

FIG. 2.—Showing increase in size of lesion in the right lung, with cardiac and tracheal displacement to the left. The left lung is clear.

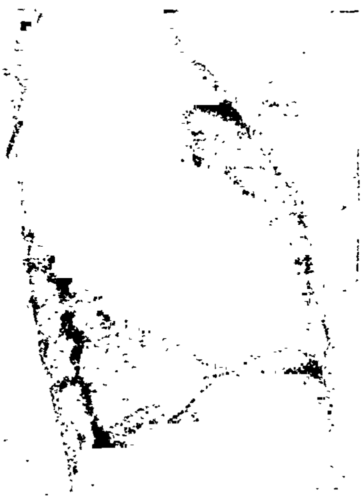

FIG. 3.—Lateral view, taken on the same date as Fig. 2. This localises the lesion mainly in the anterior part of the lung.

The commonest site for the disease is in the liver, the next frequent location is in the lung, in the ratio of about 10 : 1. Primary hydatid disease of the lung must be considered a rare form.

Klose[1] records only 4 cases of the primary form in a series of 62. In Megarth's[1] series of 93 children, only two showed the pulmonary site as early as 10 years. The secondary form of hydatid disease in the lungs may be due to rupture of a liver cyst or to metastases via the venous circulation or lymphatics.

Ortenberg[2] considers that when the disease metastasises by the blood stream the pulmonary lesion is always multiple and bilateral, the cysts are small and uniform in size, and are usually situated in the peripheral and subpleural portions of the lungs. The primary form may ante-date diagnosis for as long as six or even ten years. Ortenberg reports a case of rupture of a pulmonary hydatid cyst—probably of secondary origin—in a girl aged 12 years, with spontaneous recovery. Microscopic examination of the vomica in this case showed no hooklets; pus, elastic fibres, and alveolar cells were present. Puncture of the pleura was unproductive.

Green[3] describes a case in a child aged 11 years. The cyst ruptured into a bronchus, and microscopic examination of the vomica showed a laminated cyst wall and two scolices complete with hooklets. A blood count revealed a leucocytosis but no eosinophilia.

In 1908 Morquio[4] published in the *Archives de Médecine des Enfants* a memoir based on 12 cases. Since that time he has treated more than 100 cases. He mentions that the disease was more frequent in boys than in girls, and that the age of predilection is between 8 and 12 years. No cases were observed before the age of 4 years.

Hæmoptysis is said to occur in 60 per cent. of the cases of hydatid cysts of pulmonary origin. It may be the only clinical manifestation and varies in quantity and degree, although it is seldom very grave. A useful clinical classification is suggested by Morquio,[4] who groups his cases thus:—

(1) *Silent or latent.*—In this group there are no clinical manifestations, and the condition is discovered during routine radiographic examination—the appearances of which are characteristic.

(2) *Cases with physical signs and little or no functional disturbance.*—Repeated attacks of bronchitis are not without significance in this type. Occasionally a slight hæmoptysis occurs and physical signs may or may not be marked. A diagnosis of pulmonary tuberculosis or pleurisy is often made.

(3) *Cases with physical signs and symptoms.*—The

symptoms predominate in this group. They may be lassitude, dyspnœa on the least exertion, cough and expectoration, and sweats which are sometimes severe and persistent. The physical signs may or may not be marked.

(4) *Complicated cases.*—The pulmonary complications which may accompany the cyst are congestion, a peri-pneumonitis, lobar and broncho-pneumonia.

(5) *Cases in which the cyst ruptures into a bronchus.*—In Morquio's series of cases 50 of this variety are described.

The case to be reported here showed relatively few initial symptoms, but the physical signs were marked throughout.

DIAGNOSIS OF THE CONDITION

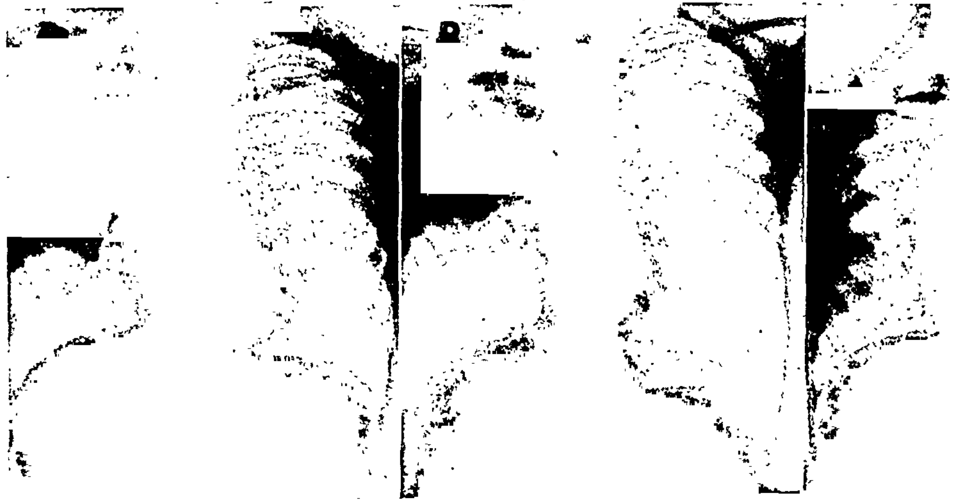
The diagnosis is clearly established after spontaneous rupture by finding hooklets, scolices, or portions of the cyst wall. Otherwise it may be fairly well confirmed by a correlation of the radioscopic appearances with the history, clinical and laboratory findings. If possible the sputum, vomit, urine, and excreta should be examined for hydatid membranes. The complement-fixation test of Axhausen, the precipitin-reaction test, and the Casoni intradermal test have been found reliable in a great proportion of cases, but it must be remembered that negative results do not negative the diagnosis and the presence of other tæniæ will vitiate the validity of the reactions. The blood count, too, typically showing an eosinophilia in hydatid disease, greatly assists in confirming the diagnosis, but again its absence does not negative it.

From the point of view of diagnosis the case reported here presented many difficulties. Owing to the initial diffidence of the patient's mother we were unable to carry out as many of the special investigations as we desired. The first clinical examination suggested a differential diagnosis between three conditions: (1) benign growth (cyst); (2) encysted effusion; and (3) pulmonary tuberculosis. The fact that the Pirquet cutaneous test was negative on two occasions was of no real significance in excluding tubercle as the cause; but with such marked physical signs as those present and the absence of any evidence of toxæmia, which one would expect to accompany these signs in a tuberculous process, this diagnosis was improbable. Exploratory needling of the chest might have cleared up the difficulty of diagnosis, but this is a case in point where this practice should be withheld *at least* until a radiographic examination has been made. In our case, especially, it was hardly justifiable in view of the graver possibilities which had to be borne in mind.

The initial radiographic examination (Jan. 28th, 1932) showed a definite lesion occupying the greater part of the right hemithorax (Fig. 1). There are various interesting features to be noted: (*a*) the increase in size of the right hemithorax, which may partly account for the lack of displacement of the thoracic viscera; (*b*) the defined lower and internal border; (*c*) the gradual shading into general haziness of the upper and outer border; and (*d*) the pronounced peak *of the diaphragm on the right side*. The condition was now considered to be non-tuberculous, and in spite of obvious difficulties a tentative diagnosis of pulmonary hydatid cyst was made on the radiographic appearances.

At first there was a complete denial of the child having associated with a dog at any period of her life, but later we were able to obtain a history that four years previously she had a wire-haired fox terrier which was bought from a stables. The dog had been ailing for two months and eventually was drowned. The child made a playmate of the dog and fondled it a great deal.

The next radiograms (April 25th, 1932) showed some bulging of the upper part of the right hemithorax. The trachea and heart were slightly displaced to the left. The lesion showed an increase in size downwards towards the diaphragm (Figs. 2 and 3). The two following radiograms—extending over a period of 12 months—showed what appeared to be improvement from a radiological standpoint. The lesion had contracted and now occupied the upper half of the right lung field. There was no cardiac displacement. The final radiogram (Fig. 6), taken on March 5th, 1934, showed evidence of fibrosis in the upper and inner part of the right lung. The trachea and heart are drawn over to the right. In the lower part of the lung field there are appearances suggesting peripneumonitis. Stereoscopic radiography suggested evidence of a localised atelectasis in the upper, inner, and anterior part of the right lung.



FIGS. 4 and 5.—Radiograms (taken at an interval of three months) showing contraction of the lesion in the right lung. There is evidence of fibrosis, and the mediastinum is slightly drawn over to the right.

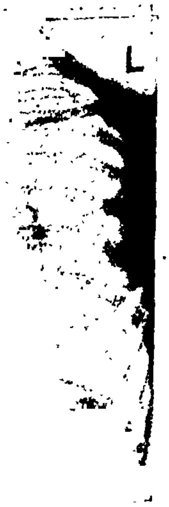


FIG. 6.—Radiographic appearance after spontaneous rupture of the cyst.

CASE RECORD

The patient was a schoolgirl, aged 8 years, and the only child. She was first seen at her home in October, 1931, at the request of the medical attendant, who suspected her of having pulmonary tuberculosis. Both her parents are alive and healthy, and there is no tuberculosis in the family. Her only previous illness was whooping-cough, from which she made a good recovery.

Present illness.—She was last quite well at the beginning of March, 1931. The first symptoms noticed were lassitude, listlessness, anorexia, and night sweats. At that period she was home from school for two weeks. She then remained fairly well until October of that year when she developed a somewhat similar attack, lassitude, anorexia, and night sweats being the predominant symptoms. There was a slight cough and scanty expectoration and ? loss of weight. She was kept in bed for three weeks. No record of the temperature was available, and no cause could be assigned to the symptoms.

Examination (Oct. 8th, 1931) at home. The general nutrition was good. The skin was normal in colour, but the mucous membranes showed some slight degree of anæmia. There were no scars or rashes present, no œdema, no incurving or ridging of the nails, and no clubbing of the fingers. No evidence of dyspnœa or cyanosis was noted, and the pulse-respiration ratio was normal. Throughout our entire observation of the case we were unable to get a specimen of sputum for examination, although this was said to be present but scanty.

The chest was well covered. There appeared to be some fullness over the whole of the right side, where movement and expansion were definitely restricted. The veins showed some prominence over the upper part of the chest wall, especially on the right side. No definite displacement of the cardiac impulse was noted. Palpation confirmed inspection. There was no rhonchal or friction fremitus present and no cardiac displacement. The percussion note was dull over the right upper lobe with some slight resistance. The area of cardiac dullness was not increased. Breath sounds were absent over the right upper lobe. Nothing abnormal was detected elsewhere in the body.

A Pirquet tuberculin test was done and this gave no reaction. It was repeated subsequently on April 28th, 1932, again with a negative result. The child was excluded from school and seen at frequent intervals up to last April.

Résumé of clinical notes.—Oct. 12th, 1931: physical signs more marked in right lung; dullness increased; coarse crepitations in right paravertebral area. April 25th, 1932: patient complained of dyspnœa on least exertion; heart slightly over to the left, otherwise no marked change in physical signs; note increase in size of lesion on radiogram (Fig. 2). July 28th, 1932: gaining weight; previous day patient had a hæmoptysis accompanied by much purulent expectoration; no systemic disturbance noted. Oct. 27th, 1932: intense bronchial breath sounds over right upper zone; pleural friction in basal region; no cardiac displacement; contraction of lesion in radiogram—apparently after partial evacuation of cyst on July 28th. Sept. 18th, 1933: still gaining weight; no marked change noted in physical signs in intervening period.

On Nov. 25th, 1933, the patient was admitted to hospital because a week previously she had been taken ill with repeated bouts of coughing. Temperature 102° F. During this time, on three occasions, she coughed up "pieces of skin," accompanied by much foul sputum. With these attacks she became very dyspnœic. She was admitted to hospital as an emergency case, and on the following morning she developed another bout of coughing and expectorated some material which was later identified as the wall of a hydatid cyst. Pus cells and bacteria were present, but no hooklets were found. During the next few days she became gravely ill, presenting symptoms of marked cardiac and respiratory embarrassment and developing an urticarial rash. Symptomatic treatment was adopted and the temperature settled to within normal limits on the sixth day after admission. Thence she made an uninterrupted recovery and was discharged on Dec. 14th, 1933.

Special investigations.—A differential white cell blood count showed percentages which were within normal limits. There was *no* eosinophilia. A Casoni intradermal test with two antigens was negative.

Recent history.—March 5th, 1934: continued gain in weight. Slight dry cough. General condition good. Slight restriction of expansion with impaired resonance over the right upper zone. Bronchial breath sounds in infraclavicular region. Pleural friction in mid-zone. Marked whispering pectoriloquy along upper dorsal spine. March 19th: no symptoms. Pleural friction disappeared, otherwise physical signs in statu quo. April 5th: patient fit and well—attending school. No symptoms. Physical signs in statu quo.

CONCLUSION

Despite the advances made in thoracic surgery during recent years, the removal of pulmonary cysts must still be fraught with grave risks and the operative mortality in children is high (15 per cent.). Spontaneous rupture is not free from danger either; immediate death from suffocation may occur or death may result from an acute intoxication of an anaphylactic nature. With reservations, the dictum of Trousseau must still be accepted—viz., "Generally speaking, the wisest course is to refrain from interference and be a watchful observer of nature's methods."

I should like to record my thanks to Dr. H. M. Williams, tuberculosis physician for Swansea, for his permission to publish this case; to Dr. W. Macdonald, hon. physician to the Swansea General Hospital, for permission to follow up the case while under his care in hospital; and to Dr. A. F. Sladden, pathologist to the hospital, for his reports on the laboratory findings.

Clinical and Laboratory Notes

EMPYEMA NECESSITATIS ASSOCIATED WITH PARAPLEGIA

By C. Allan Birch, M.D. Liverp., M.R.C.P. Lond.

LATE SENIOR MEDICAL REGISTRAR, ROYAL INFIRMARY, LIVERPOOL; DOROTHY TEMPLE CROSS TRAVELLING FELLOW

Many cases have been reported in which an empyema has ruptured spontaneously and the pus has pointed in unusual situations. The following case is recorded because of the possibility of direct causal relationship between thoracic empyema and true suppurative myelitis. Opportunities for detailed investigation before and after death were limited, but the known facts make an interesting story.

A. B., an unmarried girl aged 18, had no previous illnesses beyond scarlatina as a child and tonsillectomy at 13. She became ill with pain in the back and shivering and was thought to have influenza. Three days later her legs became weak, and on the fourth day she had a complete flaccid paraplegia with anæsthesia to cotton-wool touch and pin-prick, extending up to the middle of the thighs. She was incontinent of urine and fæces. She had no cough or sputum throughout her illness, and no dyspnœa, cyanosis, or chest pain.

The temperature was intermittent (102–104° F.) from the onset of the illness. She had no rigors. A certain amount of deep sensation returned in the legs, but anæsthesia to pin-prick extended as high as the middle of the sternum.

A few investigations were made early in the illness. A blood count showed 26,186 leucocytes per c.mm., of which 86 per cent. were polymorphs. Radiography of the spine (with a small portable machine) showed no apparent change. The Wassermann reaction was negative. She had a slight vaginal discharge, but no gonococci were present in it. At this time the urine was normal, but later she developed an acute cystitis. Physical examination was otherwise negative. A diagnosis of transverse myelitis of unknown ætiology was made. During the first four days of her illness three observers found no signs of disease in the lungs. When next seen by me two weeks later she was moribund and was not examined.

At autopsy the right pleural cavity contained about three pints of foul pus. The base of the right lung showed a small patch of consolidation and much fibrinous pleurisy. There was a patch of consolidation in the apex of the left lower lobe. The erectores spinæ were infiltrated with pus and there was a large abscess outside the vertebræ which communicated with a diffuse trough of pus in the spinal canal and in which the spinal cord could hardly be distinguished. Above the level of the seventh cervical vertebra the spinal cord was normal and the brain was normal. No localised disease of the vertebræ could be found.

There are three possibilities to be considered in this case: (1) that the initial lesion was a myelitis of unknown nature which was later complicated by a pneumonia and an empyema which invaded the spinal canal; (2) that the initial lesion was in the right chest and the paraplegia resulted from it by direct extension of pus; (3) that the lung and cord lesions arose simultaneously as part of a septicæmia.

The fact that the patient had no symptoms or signs referable to the chest at the onset is a point, admittedly not a strong one, in favour of a primary myelitis. The high initial temperature and the condition found at autopsy are in favour of an initial lesion in the lung. Blood cultures were not made. Whatever be the true order of events in this case the fact that an empyema may track into the spinal canal is shown.

A CASE OF MULTIPLE ANEURYSMS

By A. G. Sanders, M.B. Lond.

LATE SENIOR HOUSE PHYSICIAN, THE METROPOLITAN HOSPITAL, LONDON

The following case of multiple syphilitic aneurysms is sufficiently unusual to be recorded.

The patient, a Jewish woman aged 63 years, was admitted to the Metropolitan Hospital under the care of Dr. C. Worster-Drought in March, 1933, for cough and shortness of breath.

Family history.—Her husband is under treatment for neurosyphilis of the meningo-vascular type. He is now aged 61 years and was first seen in March, 1925, with a history that in February, 1924, he had a "stroke," remaining more or less unconscious for 14 days. He gave a history of specific disease 30 years before which was inadequately treated. On examination he showed right pupil greater than left, both reacting sluggishly to light and normally to accommodation; slight weakness of lower half of the left side of face; spastic condition of both left arm and left leg, left arm showing limited movement at shoulder and elbow but none at wrist and fingers. Left leg showed limited movement at all joints. All left arm-jerks greater than right; knee- and ankle-jerks brisk, left greater than right; left plantar extensor, right flexor; left abdominal reflexes absent. Gait that of spastic left-sided hemiplegia. Heart not enlarged, sounds normal, pulse 84, regular. Blood-vessels somewhat thickened. Blood pressure 140/83. Blood Wassermann reaction strongly positive. Cerebro-spinal fluid: 10 cells per c.mm., small lymphocytes with an occasional plasma cell; protein 0·045 per cent.; globulin faint trace; Wassermann reaction positive; Lange curve 122332100.

He was treated with periodical courses of Novarsenobillon and bismuth injections as well as iodides by the mouth and improved considerably. The movements in the left hand and at the left wrist returned; at the present time the arm shows only slight spasticity and he uses it well. Similarly, the left leg shows good movement and is only slightly spastic. The last cerebro-spinal fluid examination carried out in November, 1930, showed only 5 small lymphocytes per c.mm., total protein 0·03 per cent., globulin and Wassermann reactions negative, and Lange reaction 2221100000. Blood Wassermann reaction weakly positive. He remains well and is able to carry on his work as a small shop-keeper.

The only child is a daughter aged 49 years who shows no signs of syphilis and has two healthy children.

Previous history.—The patient had one miscarriage six years after her daughter was born—i.e., 36 years ago. She has never had any rashes or other secondary manifestations. Myomectomy 22 years ago.

History of present illness.—For one year the patient has not been able to bend down nor bend her head far forward as these movements brought on a "choking feeling" in the upper part of the chest. For about six months she has only been able to sip fluids as a large draught also brought on the same feeling. For three months she has become progressively short of breath, especially on exertion, while for two months she has had a harsh cough which increased the dyspnœa and also caused occasional cyanosis. She could not lie down without distress.

Present condition.—She has an occasional brassy cough with voice husky. On the right side of the neck a pulsating swelling can be seen, about the size of half an orange, and a smaller swelling on the left side. On palpation the first is found to be an aneurysm, presumably of the right common carotid artery involving its bifurcation, while the second is the left common carotid dilated to about ¾ in. diameter. The left subclavian artery is dilated and tortuous. There is a fusiform enlargement of the brachial artery at the bend of the right elbow, while the left brachial artery appears to be larger and more readily palpable than normally. No other aneurysms are found in the limbs. There is no "tracheal tug." The heart is dilated and the apex-beat felt in the fifth left interspace 3 in. from the sternal edge. The cardiac dullness extends upwards to the second space on the left side and ½ in. to the right side of the sternum in the second and third spaces. Auscultation reveals a soft, localised, systolic murmur at the apex. The aortic second sound is much accentuated, but there are no murmurs at the base of the heart nor can any be heard over the aneurysms in the neck and elsewhere. The pulses appear equal. B.P.: left 220/120; right 210/134. The lungs show mild general bronchitis. Abdomen normal. The pupils are irregular and inactive to light but react to accommodation. The tendon reflexes are all present but the knee-jerks are sluggish. Plantar responses flexor. The vocal cords and larynx are normal. The blood gives a "two-plus" Wassermann reaction and a positive Sigma test of 1·9 units.

The cerebro-spinal fluid is normal in all respects with negative W.R. The urine shows no abnormality. An X ray examination of the chest shows the following: "*Heart:* general enlargement. *Aorta:* arch is enlarged and displaced upwards and to the left. Descending aorta is also enlarged. Plaques seen in walls of arch. Diagnosis: aortitis ? atheromatous."

With several weeks rest in bed the patient improved sufficiently to return home where she has since been fairly well.

I am indebted to Dr. C. Worster-Drought for kindly allowing me to record this case and also for the notes of the husband's condition.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF OTOLOGY AND LARYNGOLOGY

THE summer meetings of these sections took place at the University of Birmingham on June 8th and 9th.

The President of the section of otology, Mr. W. J. HARRISON, was in the chair at the first session when Sir CHARLES BALLANCE read a paper on

Nerve Anastomosis

illustrated by slides and cinematograph films. He said that the earliest experiments on the suture of nerves were those of Fleurens, and that since 1895 surgeons had been uniting the peripheral end of a divided nerve to the central end of some other divided nerve of the neck. The recovery of the muscles of the face after such an operation, though often remarkably satisfactory in comparison with the preceding paralysis, was at no time functionally perfect. At the conclusion of the war he determined to try to ascertain, by the experimental method, the best procedure in operating for facial palsy. With this object, thirty experiments were carried out, in which the facial nerve was united to various nerves in the neck. At the end of six months the voluntary movement and the faradic response were normal in several of the animals, and the muscles on both sides of the face contracted together. But when the facial nerve was grafted to the hypoglossal, the descending hypoglossi, or the glosso-pharyngeal nerve, associated movements, varying from slight closure of the eyelids to contractions involving other muscles of the face and pinna, were present. Four years ago Dr. Arthur Duel, of New York, invited Sir Charles to join him in conducting surgical research and there they took up the question of the operative treatment of facial palsy. The decision to employ a nerve graft in the Fallopian canal was evolved after nearly a year of experimentation, the animals used being monkeys. There was, he said, no such thing as anastomosis of nerves. The distal segment of the nerve degenerated, and at the end of fourteen days it could be described as a bundle of tubes containing the broken-down fatty elements of the nerve sheath. The decision to perform an intertemporal operation for the cure of facial palsy was strengthened by the recognition that an injured nerve should be exposed at the site of the injury. In man, the complete or radical mastoid operation should be done before the outer wall of the aqueduct was removed. Decompression was the obvious course to adopt. In many cases it was best to expose the nerve from the geniculate ganglion to the stylomastoid foramen. A long graft was needed to fill up the gap. Neither the speaker nor Dr. Duel favoured an operation which aimed at shortening the course of the nerve by displacing it from the canal.

Expression of the emotions was, he continued, the best test in assessing whether the operation had been followed by the harmonious working of the two sides of the face. Dr. Duel was responsible for the use of degenerated grafts instead of fresh grafts, and he demonstrated their surgical value. The degenerated grafts consisted of a series of tubes filled with fatty masses due to the breaking up of the sheaths; through these tunnels the axis cylinders slid along with great facility. The use of this graft might determine the return of faradic excitability in the muscles of the palsied face in as short a period as a month. In 13 of the first series of 22 experiments on baboons, spontaneous contractions of the face muscles were observed, and in 8 of the 13 the facial nerve had been grafted to another nerve of the neck; in the remaining 5 the nerve graft operation had been done. Anæsthesia was noted to cut out the control of the neopallium. If the cerebrum was removed by section of the crura cerebri, the spasms of the facial muscles became still more exaggerated; the monkey continued to breathe, and lived on its brain stem. Neither Dr. Duel nor Sir Charles had observed, after operations on patients for facial paralysis, any spasm of the muscles, showing that in this respect the monkey differed from man.

Sir HAROLD GILLIES related his

Experiences with Fascia Lata Grafts

He said that the value of the support given by the fascia lata was comparable to that of the cock-up splint. It was essentially a palliative operation, but its use had been established, and in cases promising to recover it was a great aid in promoting recovery. There were two main methods of taking the graft: the open and the closed. In the first, a long incision was made down the thigh; in the second, a nick was made and a ring cutter inserted and a portion of graft removed. The usual positions for placing these strips of fascia lata were the centre of the lower lip, centre of upper lip, and the angle of the mouth. For paralysed eyelids he considered that the use of a temporal muscle slip *plus* its own temporal muscle fascia was best. Despite every care in asepsis, mild infection occurred in quite a considerable proportion of the cases; that was especially so if the graft perforated the mucous membrane. Sir Harold favoured the closed method, and by means of a cinematograph film he demonstrated the operation.

The subject was discussed by the PRESIDENT, Mr. LIONEL COLLEDGE, Mr. E. WATSON-WILLIAMS, Mr. HAMBLEN THOMAS, Mr. SYDNEY SCOTT, Mr. THACKER NEVILLE, Dr. DOUGLAS GUTHRIE, and Mr. HOLT DIGGLE.

Phonation and Articulation

Mr. STEPHEN JONES read a paper on Normal Phonation and Articulation, illustrated by diagrams, and Mr. V. E. NEGUS contributed one on Disorders of Phonation. He showed that it was necessary that the margins of the glottis should be even, otherwise a complete shutting off of the air current would not occur. Growths or ulcerations at the margins produced superimposed tones or noise. In the raising of pitch the contraction of the thyro-arytenoid muscle was increased; it was these muscles which imparted elasticity to the margins of the glottis. A high-pitch note was always more difficult to sustain than a low one. He maintained that the vocal cord was unnecessary for phonation. The use of the other muscles was to hold the scaffolding of the larynx in correct position during phonation. Laryngitis or laryngeal ulceration was responsible for extra puffs of air, with a resultant harsh quality of voice. He illustrated the comparative anatomy of the organs of phonation by a series of slides.

Miss FREDA PARSONS, who is in charge of the Phonetics Clinic at Queen's Hospital, and is concerned with re-education of the organs of speech and the mouth after operations, described her methods. Her main object was to instil into the patient a conception of the high function of speech, and to use every device to cause him or her—and most of her pupils were children—to feel a real joy in learning to talk distinctly. This was especially necessary, as people who were dumb and had serious speech defects were very depressed. If speech was impossible or difficult the personality became imprisoned, and, since speech was the chief means of social intercourse, failure of this function inevitably induced a feeling of inferiority. She taught her subjects to increase the flexibility of their speech organs, and the value of voiceless stops and voiceless continuance. If the tones were adequately taught, she found that the vowels fell into shape normally. For that reason she devoted special attention to the consonants. Every few days she devised some new means of sustaining the patients' interest and excitement. Miss Parsons demonstrated, in a number of children and one woman aged 56, the means by which she re-educated the speech capacity; in all the articulation was such as to form a model for some normal people. Before the exercises the woman, who had had a two-stage operation on the mouth, was unable to use the telephone; she did not fail in any of the requirements of her life.

Mr. BRAYSHAW GILHESPY remarked that the pitch of consonants was mainly in the region of 8192 double vibrations per second, or tuning fork C_6, and that the vowel sounds were situated lower in the scale—namely, between 400 and 2000 double vibrations per second. If the hearing below 2000 double vibrations was lost, there resulted great confusion in distinguishing certain vowels, apart from difficulty in hearing them, as certain pairs of the vowels had fundamental notes so close together that differences in frequencies could not be appreciated unless one of the pair possessed an overtone by which it could be recognised. People with nerve deafness failed in reference to their consonants. In conclusion, he remarked how little was taught of phonetics in standard text-books on ear and throat work.

Dr. T. C. GRAVES (Birmingham) read a communication, supported by two cases, on

Sphenoidal Sinus Infection in Relation to Mental Disorder

He showed that when mania arose from the existence of closed foci of sepsis the ordinary sedative drugs failed to remove the excitement. Both the patients had serious circulatory disturbance, which rendered the subjects unfavourable risks. The first patient, a woman aged 25, was certified, for the first time, in April, 1933, and was discharged in the following November, since when her recovery had been maintained. She had had nasal catarrh, and, later, cacosmia and cacogeusia; also headaches and soreness in the right temporo-parietal region, and the frontal at times. There was a history of two nervous breakdowns. She lost weight, developed faulty habits, was violent, and had severe general asthenia. Pus was found in the right sphenoid and left antrum, and was drained. Both ethmoids were hæmorrhagic. Septic tonsils were removed, and injections of colloidal sulphur were given. Improvement followed these measures, and she began to get well.

The other case was that of a woman aged 41, who was admitted to the mental hospital in August, 1929, and was not discharged until April, 1934. There was a history of familial chronic nasal and conjunctival sepsis, and she had frequent severe headaches and influenza. There were five normal pregnancies, and during the sixth she had an enlarged thyroid, and tremulousness, with cyanosis and vertigo. Periods of confusion and anger alternated with sleepiness. On admission she was grossly obese, and her tonsils were septic; also she had purulent conjunctivitis and blepharitis. Blood Wassermann was negative. There was evidence of sinus and tonsillar disease. Her menstrual function was profuse. Her mental state seemed to be secondary dementia with hallucinations and excitement. Examination showed infection of both sphenoids, yielding *B. influenzæ*, and the sinuses were drained intranasally. Following this there was mental improvement, and sedative drugs were no longer needed.

Mr. HAROLD ROUND demonstrated in a number of patients a remarkable dexterity and ingenuity in rectifying severe facial deformity following operation, and after removal of long-standing facial lupus.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A MEETING of this society was held at Leeds on May, 11th, with Prof. DANIEL DOUGAL (Manchester), the president, in the chair.

Puerperal Fever and Peritonitis

Mr. D. W. CURRIE read a report on a hospital epidemic of puerperal fever which lasted from the end of February to the middle of March, and was due to a hæmolytic streptococcus. Ten women were affected and four died. In comment on his investigation, Mr. Currie pointed out that the hospital had been over-full for several days, the average daily in-patients being about 120 for 108 beds. The number of patients in the labour department varied from 9 to 15 for 10 beds.

> Three patients were in the labour department over three days, and were frequently moved from the first-stage ward to the labour ward and back; although the linen was changed at each move, it is possible that a septic patient soiled more than one bed. This danger is obviously liable to occur in a large central labour ward such as the one involved, which has six beds.
>
> One definitely septic patient was moved after delivery to a clean lying-in ward. She should have been sent to the isolation block, or at any rate to a side ward.
>
> There was often delay in transferring feverish patients from the large lying-in wards to the side wards. This was due to the difficulty of managing the beds owing to overcrowding, but probably explains the infection of the two last patients.

He deprecated the practice of admitting "failed forceps" and other probably infected cases into the labour ward with clean cases. He also stated that the blankets and bed-pans had come under suspicion as possible vehicles of contagion.

Mr. Currie then gave a brief account of 17 cases of puerperal peritonitis operated on by him in the last four years. Clinically they were divisible into three groups—peritonitis following abortion, atypical peritonitis early in the puerperium, and typical peritonitis late in the puerperium. In the atypical group there were nine cases with one recovery. The most constant signs were distension and free fluid; others were a sudden rise in temperature and pulse-rate, slight superficial tenderness, and diarrhœa. The treatment in each case was laparotomy and drainage. Until lately a tube had been left in the pouch of Douglas and removed after three days, but the drainage was slight. Latterly, therefore, the tube had been inserted just into the cavity and left for a week; and in the successful case thin serous fluid drained for three or four days, then changing to thick pus. Another patient had her operation on the third day, after complaining of severe abdominal pain. She had typical signs of appendicitis with peritonitis, and the appendix was gangrenous: she recovered. Three cases late in the puerperium had signs typical of peritonitis; all three had local abscesses and recovered after drainage. Four cases were post abortum. This class was less dangerous because the infection tended to be limited to the pelvis. Two were drained by posterior colpotomy, and recovered; two died after abdominal drainage.

Endometriosis and Ovarian Dysfunction

Dr. T. N. A. **Jeffcoate** (Liverpool) read a paper in which he said that endometriosis is a state in which there is excessive formation of endometrial tissue in the body, comparable in all respects with overgrowth of the uterine mucosa. As it was established that endometrial hyperplasia is due to the action of œstrin, and the condition had been produced experimentally in castrated women and animals, he thought it logical to conclude that excessive œstrin secretion was the most important factor in the growth of endometrioma in any site. He had made a clinical and pathological study of 111 patients with endometriosis, to determine in each case the presence or absence of the forms of ovarian dysfunction characterised by excessive secretion of œstrin—namely, metropathia hæmorrhagica, hyperfollicular disorder, and granulosa-cell tumour. The results were as follows:—

Endometrioma of the uterine wall alone (33 cases).—The average age of the patients was 45·5; the youngest was 30 and the oldest 57. Most of the patients were sterile (over half of the married) or had not conceived for some years before operation. The commonest symptom was excessive loss, and as a rule this was of the type occurring in metropathia—i.e., metrostaxis, often preceded by amenorrhœa. A part of one or both ovaries was examined in 7 cases. One or more follicular cysts were present in 4 patients; in a fifth a degenerating corpus luteum was present on the ninth day of the cycle, which strongly suggests hyperfollicular disorder. Recent lutein tissue was not seen in any other case. The uterine mucosa was examined microscopically in 19 cases (including 5 of the specimens reported on naked eye), and in 18 specimens the features of hyperplasia were present and the appearance of the resting stage was constant except that in two cases the stroma was œdematous. In the endometriomata themselves all the characteristics of hyperplasia were found in 29 specimens out of 34. It is submitted that the frequent finding of all features of hyperplasia in the endometrioma, with similar changes in the uterine mucosa, can only be caused by the influence which determines the latter—namely, œstrin. The time of the operation in relation to the date of the last period was noted in all cases. At least 21 should have shown premenstrual or menstrual features in the uterine mucosa, or the tumour, or both, but the secretory phase was present in two specimens only (both mucosa and endometrioma of one case). The evidence appears conclusive that most of the patients were suffering from a disease analogous to metropathia, while 2 certainly, and probably 5, had hyperfollicular disorder.

Extra-uterine endometriomata (78 cases).—Of these patients 46 showed no uterine involvement. The average age was 38·4: the youngest was 21 and the oldest 53. The age-incidence corresponds to that of hyperfollicular disorder rather than that of metropathia. Nearly half of the married were sterile, and of the parous many had long periods of sterility before operation. The commonest symptom was excessive bleeding (51 patients, in 27 of whom the lesion was entirely extra-uterine): 22 had metrostaxis, often preceded by amenorrhœa: 16 had menorrhagia, and 13 epimenorrhœa or epimenorrhagia. This, especially in the absence of uterine endometriosis, is striking. The appearance of the ovaries was not discoverable in 12 cases. Follicular cysts, often multiple, were present in one or both ovaries in 29 of the 67 specimens. These cysts were unaccompanied by recent lutein tissue, save in one instance in which the ovaries were removed from a patient with epimenorrhagia. The uterine mucosa was examined microscopically in 30 cases, and 28 showed hyperplasia and adenomyosis. In 8 cases the stroma was œdematous, possibly indicating hyperfollicular disorder. The large number presenting œdema of the stroma corresponds with the lower age-incidence in this group, and also with the higher incidence of epimenorrhagia. Of 79 specimens, 67 showed all the criteria of endometrial hyperplasia, though there was slight œdema of the stroma in 27. In the other 12 the small amount of distortion of the endometrial elements made it impossible to determine the presence or absence of hyperplastic features. The time of the operation in relation to the date of the last period was noted in all cases; at least 37 specimens should have shown menstrual, premenstrual, or post-menstrual changes in the tissue of the mucosa or of the endometrioma; these features were only found in 2 cases.

In both groups Dr. Jeffcoate considered it had been shown that endometriomata are always associated with ovarian dysfunction. Endometriosis occurred at the age at which dysfunction is common, and the associated sterility could be attributed to absence of ovulation. The histological findings in uterus, ovaries, and tumour, fitted in exactly with the theory of the ætiology he had advanced. The occurrence of fibromyomata with or without endometriomata was probably, he thought, due to the same factor. Clinically these tumours appeared at the same age-period as ovarian dysfunction, and were accompanied by the same symptoms—menorrhagia and sterility. Pathologically, specimens containing fibromyomata always showed evidence of ovarian disorder, such as follicular cysts and endometrial hyperplasia.

In conclusion, Dr. Jeffcoate maintained that his view of endometriosis explained better than any other the symptoms and pathology of the disease. It accounted for the recurrence of these tumours in patients who had had conservative operations, and explained why they did not develop when castration by operation or radiation has been performed. He added that although the ovarian disorder had been regarded for purposes of convenience as primary—that is, in relation to the pelvic lesions—the cause of the alteration in behaviour of the ovaries lay almost certainly in the pituitary gland.

Mr. A. **Gough** described a case of menstruation starting at the age of 29, and showed specimens of a syncephalus thoracopagus (subgroup diprosopus diophthalmus) and of a cervical fibroid obstructing labour.—Dr. E. A. **Gerrard** read a communication on dystocia due to rigid cervix following colporrhaphy.

EDINBURGH OBSTETRICAL SOCIETY

A meeting of this society was held on May 9th, with Dr. **Oliphant Nicholson**, the president, in the chair.

Cæsarean Section

Dr. W. F. T. **Haultain**, with Dr. E. M. **Robertson** and Dr. J. B. **Dewar**, contributed a study of 463 cases of Cæsarean section with special reference to the late results in 174 cases, particulars of which were obtained by writing to all the patients who had the operation at the Royal Maternity Hospital, Edinburgh, during the years 1925–31. It was found that the general health of the mother was usually excellent in the years after the operation. About 11 per cent. stated that they were not in good health, but as a number of these women suffered from cardiac disease, this was not surprising. Only 15 per cent. suffered from any abnormality of the menstrual periods, and it was interesting to note that amenorrhœa and scanty menstruation were as common as menorrhagia. Dysmenorrhœa was present in 7 per cent. of cases and was chiefly premenstrual in type. The most interesting result of the investigation, however, was the fact that in some 63 cases in which operation might have been followed by a pregnancy, no pregnancy resulted. It was difficult to account for this high sterility-rate. The fact that 14 patients were delivered naturally in the pregnancies following Cæsarean section showed that the old saying, "once a Cæsarean, always a Cæsarean," was by no means true in this series. Pain probably or possibly due to the operation was present in nearly 20 per cent. of the cases, but in only 8 per cent. was it sufficient to make the patient seek medical advice. Urinary symptoms were present in 13 per cent., the predominant complaints being frequency and painful micturition. Constipation was prevalent as a new symptom in 12 per cent. of the patients operated upon, and could be traced as a cause of pain in a number of those who complained of this symptom.

Vaginal Discharge of Non-infective Origin

Dr. R. CRUICKSHANK and Dr. A. SHARMAN (Glasgow) pointed out that an excessive discharge per vaginam might arise from any one of three sources—vagina, cervix, or uterus.

The tubular glands of the endometrium were the source of a small quantity of watery and highly alkaline secretion from the normal uterus. The secretion from the racemose glands of the cervix was thick, mucoid, normally small in amount, and definitely alkaline, the pH ranging from 8·0 to 9·0. The normal vaginal secretion—not a true secretion since there were no glands in the vaginal epithelium—was white, cheesy, highly acid in reaction and consisted of epithelial squames, Döderlein's vaginal bacilli, some transudate and lactic acid. The lactic acid, which was responsible for the high acidity, resulted from the breaking-down of glycogen in the vaginal epithelial cells, probably by bacterial action. These conditions were found in the vagina during reproductive life and for a short period after birth when glycogen was also present in the vagina. The deposition of glycogen there was probably controlled by the œstrogenic hormone.

By laboratory examination it had been possible to classify a series of over 40 cases of virginal leucorrhœa into two categories—infective and non-infective. In the first the organism was usually *Trichomonas vaginalis*. Among the non-infective cases hormonal disturbance was often strongly suggested, either by the patient's "make-up" or by gross menstrual dysfunction. Spontaneous remission of the discharge tended to occur at intervals. The average age at onset was low (19 years). Sometimes the complaint dated from puberty and in three of the series excessive discharge was noted before menstruation had begun. In four out of five cases examined, excess of œstrin was present in the urine, while radiological examination showed an unusually small sella turcica in three of five cases. On vaginal examination no lesions, inflammatory or otherwise, were discovered. Excessive discharge of non-infective origin might occur in non-virginal patients and in pregnancy it was very common.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE ASSOCIATION.—We published an abbreviated report last week (p. 1231) of a discussion upon the Treatment of Peptic Ulcer which took place at a special meeting of the Fellowship on May 30th. It should have been mentioned that a verbatim of this report would appear in the issue dated June 12th of the *Post-Graduate Medical Journal*, the organ of the Fellowship of Medicine, a copy of which costs 2*s*.

INTERNATIONAL CONGRESS ON RHEUMATISM IN MOSCOW

MAY 3RD–7TH, 1934

(FROM A CORRESPONDENT)

DELEGATES from 26 countries represented at the recent IVth International Congress on Rheumatism in Moscow had every opportunity of judging for themselves the degree to which the modern U.S.S.R. is desirous of welcoming western medical ideas, and the stage to which she has herself progressed. With regard to the former, it would be difficult for them to have returned home without feeling that they had been welcome guests whose opinion had been sought and valued. The progress of medical science is difficult to assess during a stay of rather less than a month. Certain impressions were shared by a majority of those who attended the congress, and who took part in the subsequent tour of Southern Russia.

At the outset it is a little bewildering for representatives of "capitalistic" countries to find that public health under socialism includes the whole of medicine and surgery. "When a citizen falls ill from any cause, it is the duty of the State to do something, and to continue to do something until he is back at work in his original condition of health." This was said by a distinguished professor of medicine in the course of an address of welcome to the delegates. How far this ideal of state medicine has been put into practice it would be hard to say. It seems true of the highest grade workers in the large factories, but in the country districts, medical aid is probably hard to come by and far less highly organised.

In the large towns there is evidently no lack of doctors; in one hospital of 500 beds the medical staff numbered over 200. On the other hand, nurses seemed scanty; it was mentioned to us as one of the contributory causes of the predominance of women doctors that much of the more skilled nursing work, such as the giving of enemas, medicines, and feeding, falls upon the medical staff. Another is the comparatively poor pay received by the medical man. The social position of the medical profession has however risen since the revolution, at which time the doctor was classed as a category III. worker, and as such found it difficult to survive. At the present time he draws a monthly salary about equal to that of the average factory worker (but far below that of the skilled engineer), and this sum is raised by 20 per cent. after two years of satisfactory work, and thereafter up to a fixed maximum. He can retire on a 75 per cent. pension at the age of 55, but need not do so until 70. Every doctor must hold at least one post under the State; should he be ambitious, or require a double salary, he may hold two or even more such posts provided that he works in each for a minimum of six hours daily, and "does some scientific work in his spare time." During the last two years the medical man has earned the privilege of sending his children to the university, and of buying his food at the same price as does the worker.

The attitude of the majority of the medical men we spoke with was one of enthusiasm and hope for the future. It was pointed out that in former times there existed no plan for a system of public health, whilst during the last seventeen years an ambitious and idealistic plan embracing the whole scope of medical science has been worked out, and is partially in operation. It has naturally proved difficult for the older men to adapt themselves to the new régime, although in many cases they have done so with apparent success. Many are occupying chairs. They are however subject to political supervision by their juniors. In every hospital a "purge" is called for at periods of three years, when a joint meeting of the complete staff from senior physician to furnace-men is held, and criticism of all from all is encouraged. Every action criticised must be defended. In Odessa, a radiologist to the State hospital had recently been dismissed for diagnosing a gastric ulcer in two cases, both of which died subsequently from other causes. The complainant was one of the nurses. The system is stimulating and probably healthy but offers opportunities of abuse.

Delegates to the congress had the unusual honour of an invitation to dine in the Kremlin as guests of Kalinin, the ex-peasant President of the U.S.S.R. This was no doubt in recognition of the fact that they represented the first international gathering held in Moscow since the beginning of the new régime. We were also received by Kuminski, the 34-year old Commissar for Health, who is a medical student. Sight-seeing tours and special performances at the opera were arranged in addition to the heavy programme of sanatorium and clinic visiting. The 6000 miles journey was made in a special train which was met everywhere by representative delegations from the ministries and medical societies. In Kiev, the new capital of the Ukraine, we were received in the magnificent new Academy of Sciences, whose President informed us that they now summarised their proceedings in English.

It was interesting to find the modern generation of medical men all over the country thinking but little of drug therapy. Physical medicine is acclaimed as the rational therapeutic procedure, and fine institutes for this purpose are erected in all towns. Due in part no doubt to the scarcity of drugs, there is a definite swing of opinion in this direction. Treatment and prophylaxis were emphasised everywhere as the aim of medicine; of diagnosis less was heard, and it may be that the length of the present medical course is insufficient to provide adequate training in diagnostic method. Much use is being made of the natural resources of the country; in the spas of the Caucasus, and in the Crimea and adjoining Black Sea riviera, countless sanatoria and rest-houses have been put up for all classes of worker. The army sanatorium, just completed at Sotchi by an American architect, is said, with little fear of contradiction, to be the finest in the world. It may be noted that everywhere the finest buildings are for the use of the army or the coming generation—kindergartens, creches, and schools. Great importance is attached to adequate holiday and rest periods for the workers in suitable surroundings as a preventive of disease; organisation of this kind has, it is said, reduced the incidence of chronic arthritis by one-third in the last ten years.

While it may be too soon to judge of the scientific accomplishments of the new Russian medicine the tour certainly revealed much of scientific interest, heightened no doubt by the new approach to familiar problems as a result of the break with more traditional schools of thought.

REVIEWS AND NOTICES OF BOOKS

The Medical Annual

A Year Book of Treatment and Practitioner's Index. Edited by H. Letheby Tidy, M.D., F.R.C.P., and A. Rendle Short, M.D., F.R.C.S. Bristol: John Wright and Sons; London: Simpkin Marshall Ltd. 1934. Pp. 644. Illustrated. 20s.

In the introduction to the 1934 volume the editors record an attempt to meet the criticism that this book is designed too much for the specialist and not enough for the general practitioner, and suggest with good reason that the family doctor will find useful material in the present issue. Dr. H. Letheby Tidy has succeeded the late Dr. Carey Coombs as medical editor. This year we have browsed chiefly among the medical entries, though those devoted to surgery and the specialties certainly deserve no less attention. Special interest attaches to the sections on anæmia and on dietetics, which are compiled with particularly sound judgment. Ketogenic diet was briefly mentioned in the 1933 volume, but the reference was too sketchy to be of any real value. Now more space is devoted to it under the headings of pyelocystitis and pyuria in children; a sample diet is given, also figures showing that satisfactory results have been obtained in a considerable number of cases. Recent work on vitamins is discussed in some detail, and this summary will be appreciated by those who try to keep pace with this rapidly growing subject. Due prominence is given to the successful transmission of influenza to ferrets, recorded in our columns a year ago. Alkalosis is discussed in connexion with the intensive alkali treatment of gastric and duodenal ulcers. When this form of treatment was first introduced much was written and spoken about the dangers of alkalosis; subsequently it was found that this complication was a relatively rare event. It is now a little disturbing to hear that of 200 cases treated in this way at St. Thomas's Hospital nine showed characteristic symptoms of alkalosis, and a detailed clinical picture is given. The great importance of its early recognition is clear from the fact that the symptoms are ignored, and alkalis are persisted with; the patient will die in coma, but if the treatment is stopped he rapidly recovers. The section on insomnia will be read with particular interest in view of the recent controversy over the uses and abuses of the barbitone derivatives.

The evergreen discussion on the significance of low voltage electrocardiograms is continued in this year's volume. Last year two investigators were reported as having come to the conclusion that low voltage electrocardiograms—i.e., 5 mm. or less—were of serious prognostic importance in a patient with heart disease. During the year other workers have published figures which limit the serious significance to low-voltage curves in lead II. or in all three leads, and emphasise the fact that no low-voltage curve is of great importance unless considered in conjunction with the clinical picture as a whole. An interesting report on the effects of age on the electrocardiogram should help to extend our knowledge of the variations from the so-called normal which can be safely neglected. Those interested in the study of stammering will find a long article on this subject explaining the basic difficulties of the stammerer and methods for circumventing them. The section on asthma records no outstanding advances during the year. The selection of the most significant among the very numerous contributions to the subject of rheumatic disorders must have been a difficult task; a helpful account is given of the International Rheumatic Congress held in Paris; also of the report of the Strangeways Collection, and of the report of the British Medical Association's committee. The article ends with an extensive bibliography.

In endocrinology the pituitary body has recently received much attention; an adequate account of our knowledge up to date is given, based chiefly on Cushing's work. A special article on National Health Insurance practice provides a historical summary and brief account of the present position of panel practitioners which contains a mass of condensed information which should be very useful to those who are puzzled by the intricacies of the service to which they belong.

---

1. Modern Treatment in General Practice

Edited by Cecil P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., Editor of the *Medical Press and Circular.* London: The *Medical Press and Circular.* 1934. Pp. 426. 10*s.* 6*d.*

2. Treatment in General Practice

Second edition. By Harry Beckman, M.D., Professor of Pharmacology at Marquette University School of Medicine, Milwaukee, Wisconsin. London: W. B. Saunders Company. 1934. Pp. 889. 45*s.*

1. The 56 articles of which this volume is composed originally appeared in the *Medical Press and Circular.* A statement by the publishers that the articles are written for the general practitioner reveals the difficulty in which the editor has been placed in deciding what medical information is particularly needed by the general practitioner which is not needed by the whole medical profession. Most of the essays are useful compilations of accepted views, and the authoritative tone of many of them is justified by the positions of the writers. The publishers can fairly expect a large circulation for the volume in response to its modest price.

2. Though described as a book on treatment this is, in fact, a text-book of general medicine, including dermatology and obstetrics. Dr. Beckman's method, and a very effective one, is to preface each article on treatment with a short historical and clinical summary of the disease concerned. Throughout he contrives to be comprehensive without being tedious, and definite without being dogmatic. Moreover, he has an engaging trick, not overdone, of asking the reader questions without himself supplying the answers. Among many other interesting methods of treatment discussed are the use of normal beef-serum in the treatment of anthrax, and of glucose-insulin-antitoxin in diphtheria. There is a valuable note on the management of diphtheria carriers. Dr. Beckman believes that all children, from six months to six years, should be immunised against this disease. Talking of the "influenzal" group of disorders, which he lumps together under the comprehensive term "Catarrhal Fever," he has nothing but scorn for the doctor who sticks heroically to his post with influenza upon him. His advice is "Go home when you feel it!" "Glandular Fever" (in inverted commas) is given as a synonym for epidemic sore-throat; true glandular fever is considered separately. The convalescent serum and adult whole blood-serum treatment of measles is well described, and the author wonders if all medical students know how to support an inflamed scrotum in mumps—presumably a reference to the time-honoured use of an empty champagne bottle. For pain or restlessness in pneumonia he advocates the opiates, though some will dispute the wisdom of giving morphia, for example, except in the early stages of that disease. The treatment of rheumatic fever by cinchophens and other methods less well known than salicylates is fully described; also chorea by nirvanol. Dissuasion, says Dr. Beckman, is the best sedative in typhoid delirium. The account of the modern treatment of syphilis is, perhaps, one of the best things in the book; it is taught that repeated negative C.S.F. Wassermann reactions should be the only acceptable standard of

cure. Some fourteen pages are devoted to meth
of inducing anæsthesia in obstetrics. Some practi
obstetricians will question the wisdom of deepen
anæsthesia in non-instrumental deliveries at
moment when the head is crowning. This is essei
ally the time when, by conscious coöperation betw

Physics for Medical Students

A Supplementary Text-book. By J. S. Roge
B.A., M.Sc., F.Inst.P. Edited by T. H. Lai
F.R.S. Melbourne: Melbourne University Pre
Pp. 205. 11*s.* 6*d.*

This attractive book may well make us won
whether the medical student of to-morrow is goi
on in the same old way, learning his physics beca
he has to, or whether he is going to learn it w
a definite idea that it will be of assistance to him
medical work. Mr. Rogers has called his work
supplementary text-book, and certainly the mate
with which it deals is still outside the scope of
premedical of most universities. The subject mat
is well chosen, and in practically every branch
physics the author has taken up just those aspe
which seem to weld into medical science. T
brings us back to our starting point. As medi
science enlarges its borders in ever-widening circl
will it still be possible for those trained for the gene
practice of medicine to acquire sufficient knowled
of the basic sciences to equip them to tread th
outer regions, or will these have to be explored
others whose discipline has been deeper and l
wide? In any case this book is of a type of whi
more will be needed in the future.

Aids to Sanitary Science and Law

Second edition. By C. F. White, M.B., Ch.
D.P.H., D.T.M., Medical Officer of Health, P
of London; and H. Willoughby, M.R.C.
L.R.C.P., D.P.H., D.T.M. & H., Assistant Medi
Officer, Port of London. London: Baillië
Tindall and Cox. 1934. Pp. 321. 4*s.* 6*d.*

This little book, published in 1926, has been revis
with the object of bringing it up to date. It is intend
to include in small compass the sort of informati
which may be useful, as a supplement to knowled
obtained from larger text-books, to those studyi
public health for the D.P.H., for a medical qualific
tion, and for various other qualifications.
deals in 14 chapters with water-supply, air a
ventilation, food, sewage and refuse disposal, sit
and buildings, climate and meteorology, infecti
and disinfection, school hygiene, infant welfa
industrial disease and hygiene, tropical diseas
parasites, vital statistics, and sanitary law. This is
wide field to cover in a book of this size and comple
information cannot be expected. It would see
impossible, indeed, to deal with a subject like vit
statistics in ten small pages, and the many inaccuraci
and misleading statements in this chapter mar t
book. The chapter on sanitary law, also, is not

entirely successful attempt at compression, and space is wasted in description of procedure for repair, closure, and demolition of houses and the scheduling of insanitary areas according to the Housing Act, 1925, which were amended by the Act of 1930, some reference to which is made elsewhere. It is strange, too, to read in 1934 that the Vaccination Acts are (sic) administered by boards of guardians.

It is admittedly hard to know what should be selected from the wide province of sanitary science for those who are still students—even post-graduate students—but at least they ought to get nothing which is out of date and nothing which is not strictly accurate.

1. The Dermatergoses or Occupational Affections of the Skin

Fourth edition. By R. Prosser White, M.D., C.M. Edin., M.R.C.S. London: H. K. Lewis and Co., Ltd. 1934. Pp. 716. 35*s.*

2. The Common Diseases of the Skin

Second edition. By R. Cranston Low, M.D., F.R.C.P., Consulting Physician to Skin Department, Royal Infirmary, Edinburgh. London and Edinburgh: Oliver and Boyd. 1934. Pp. 317. 12*s.* 6*d.*

1. This work has become the standard text-book on its subject in all English-speaking countries. Its author, an excellent portrait of whom faces his memoir in this edition, died in his eightieth year last January, content that he had created a lasting record of an increasingly important branch of medicine. A reduction in the size of the type has reduced the number of pages from 734 to 716, although a considerable amount of new material has been added, with 14 new illustrations and an amplification both of the general index and that devoted to authors' names. The amount of information contained is really monumental, and must be of the utmost value to factory surgeons, dermatologists, assessors, and referees, and in the complicated cases that are continually being fought and discussed both in and out of court under the Workmen's Compensation Act, 1906. The abundant references—as many as six or seven in a footnote to some pages—bear witness to the energy and industry applied by the author and by Miss Anne Newbold, who compiled the indices in their collection.

The general plan and the headings of the 12 chapters remain unchanged.

2. The author of this excellent little book on the common diseases of the skin has contributed much to our knowledge of the mechanism of cutaneous allergy. The chapter on eczema alone is worth the modest cost of the whole volume. In general arrangement it follows the classic outlines of the larger text-books, and the 18 chapters are apportioned with due regard to ætiology where this is certainly known, and to the ruling clinical features where it is doubtful or obscure. The illustrations and diagrams reach a high standard of reproduction. Interesting examples of the diagrammatic method are the small line-drawing depicting the author's theory of the histopathology of alopecia areata (p. 161) and the anatomical diagram of the common sites for the eruption of herpes zoster of the head and face. Those depicting histological structure display great skill in indicating all that it is necessary for a student or practitioner to know, and no more detail than is essential.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

VI.—TECHNIQUE OF STERILISATION

There must be few, if any, surgeons in this country who have or would wish to have any large experience in operations performed to render procreation or conception impossible. Vasectomy may be performed as part of the operation of suprapubic prostatectomy, and salpingectomy when there is strong medical reason for preventing pregnancy. In both these cases the operation may be regarded as prophylactic, in the first place to prevent epididymitis, in the second to avoid the dangers of pregnancy or labour in special cases. These cases present no ethical problem to the surgeon; provided the operation is safe and effective the justification is clear. It is not quite the same, however, when the operation is to be performed in the interests of the community or of the race, rather than in the interests of the patient and for a definite therapeutic indication.

Apart from the legal aspect—which it is presumed will shortly be made clear—the surgeon may have a doubt in his mind whether the good of the community constitutes a sound ethical justification for such an operation according to the spirit, if not the letter, of the Hippocratic oath. Though compulsory sterilisation need not be considered, seeing that it has been condemned by the Brock Committee, the consent of a mentally defective person may not entirely remove his doubts. The committee has however made out a strong case for voluntary sterilisation in certain classes of mental defect, and it is probable that the majority of surgeons will be convinced by the evidence and conclusions set out in the report. This evidence was conclusive on the essential point that sterilising operations (vasectomy and salpingectomy) produce only the result desired and have no ill-effect on the health or sexual life of the individual. On one point the committee was unable to give a definite opinion—viz., whether vasectomy performed before the age of puberty would interfere with physical maturity—and for that reason they were not in favour of the operation being performed until maturity was reached. Since the report was published, however, animal experiments carried out by Mr. J. Hammond, F.R.S., at the School of Agriculture, Cambridge, have shown that ligature of the vas before sexual maturity does not interfere with physical or sexual development or capacity for sexual intercourse (see letter from Mr. C. J. Bond, Brit. Med. Jour., Feb. 3rd, p. 212).

It is not only in cases of mental deficiency that sterilisation may be required. In most instances in which the writer has had occasion to do these operations the indication has been blindness in men and women who wish to get married. The committee of the institution by which these people are employed and cared for believes that it is undesirable from every point of view that children should be born to blind parents, and it is on these persons, at their own request and that of the chairman of the institution, that most of the operations have been performed. Sometimes it is the man who wishes to undergo the operation, sometimes the woman. When one considers the miserable fate of a child born to such parents, doomed to be separated at once from its parents and likely (in some of the cases at least) to be blind, one feels that sterilisation in cases of this sort is reasonable and humane.

Vasectomy and salpingectomy are the methods advocated by the Brock Committee, and no others need be considered. Castration, ovariotomy, and hysterectomy have disadvantages so obvious that they could rarely, if ever, be called for. Sterilisation in the female by means of X rays was considered and discussed in the Brock report and it was suggested that this method might occasionally be employed when, in the opinion of a psychiatrist, operation would have an unfavourable effect on the mental condition of the patient. One objection to X ray sterilisation is that, to be effective, a heavy dosage is required, which would probably (though perhaps not necessarily) completely destroy the functional activity of the ovaries and bring about an artificial menopause. Another is the risk of an ovum which has not received a fatal dose of radiation continuing to develop in a damaged form leading to defective or monstrous offspring.

VASECTOMY

This is satisfactorily performed under a local anæsthetic. The skin of the scrotum having been prepared in the usual way, the spermatic cord is taken up by the thumb, index and middle fingers of the left hand and the vas identified at the back of the cord and manipulated into a subcutaneous position. It is held there firmly with the skin stretched over it, while 1–2 c.cm. of 1 per cent. novocain is injected into the skin over the vas. It is convenient at this stage to fix the vas by a pair of light towel forceps (preferably with blunt points) below the point at which it is steadied by the fingers; the fingers should not be moved until the incision has been made. The vas is exposed by an incision about half an inch long and it is then secured by forceps or by passing a needle and catgut ligature under it. The fingers of the left hand may then be removed, and the vas ligatured above and below and divided between the ligatures. The wound is then closed. In most cases patients have been kept in bed for a day or two, though probably there is no necessity for this.

Vasectomy by this method is very simple and has the advantage over open dissection that there is less risk of injury to the spermatic vessels. It is generally advised that the incision should be as near to the external abdominal ring as possible; the important point is to choose a place at which the vas can be identified with certainty and held securely in a subcutaneous position while the incision is made.

As there is no definite evidence as to the duration of life of spermatozoa in the seminal vesicles, it is advisable, as suggested by Mr. Bond in his evidence before the committee, to forbid intercourse for a period of about three weeks after vasectomy.

SALPINGECTOMY

Simple ligature of the Fallopian tube is by no means an infallible way of preventing conception; even after ligature and division of the tubes cases have been reported where pregnancy has occurred. In fact it may be said that even after the most radical salpingectomy there is a remote possibility that an ovum may reach the uterus. However, for all practical purposes the usual method of performing the operation—as, for instance, after Cæsarean section—may be regarded as adequate. As this operation is only likely to be performed by gynæcologists or general surgeons of experience (as recommended in the report) it is hardly necessary here to go into details of technique. The writer's practice is to divide the tube about half an inch from the uterus, ligature the divided ends and to bury the proximal stump under the peritoneal covering of the uterus. A fold of the broad ligament may be stitched over the incision to obviate the possibility of a coil of bowel becoming adherent.

ASSURANCES TO THE PATIENT

If, as is here assumed, sterilisation is to be voluntary, it is desirable to go very carefully into the question both of efficiency and of possible risk. The Brock Committee inquired of a number of teaching hospitals in London and elsewhere, obtaining definite information from 22 places. Judging by the replies it seems quite clear that no prejudicial mental or physical effects have been known to follow double vasectomy; and the same is true of double salpingectomy, except that occasionally some regret may have been expressed for the loss of fertility. The Californian experience, as already noted, is equally definite on the point.

So much for the after-results. The operation itself may be regarded practically as free from risk in the case of the male; even the minor degree of shock which may follow ligature of the vas is avoided in the official German method, the vas being drawn within reach by passing a director behind it and simply divided, thus avoiding interference with the network of sympathetic and parasympathetic fibres contained in its sheath. There seems no reason to regard this simple division of the vas as likely to lead to restoration of the lumen. In practice urologists are well aware of the technical difficulties of restoring the lumen of a vas which has been narrowed or occluded by inflammation. American experience, however, suggests that vasectomy need not be regarded as permanent; a careful survey in California has shown that with proper technique operative restoration of fertility is not only possible but has been accomplished.

The position is rather different in the female, for although the risk to life of the operation may be slight it has to be taken into account. A surgeon has estimated the risk as comparable to that involved in a quiescent appendicectomy. There is, too, in the case of the woman no guarantee that sterilisation will be effective. Gynæcologists recognise the remarkable regenerative power of the Fallopian tube, and experimentally both crushing and tying operations have proved no safeguard against pregnancy. It was long supposed that the technique described by M. Madlener in 1919 had effectually circumvented nature. His method was to raise a knuckle of tube at its mid portion, crush it to paper thinness, and tie a ligature around the furrow, the loop thus including two portions of the tube and a portion of the mesosalpinx. Visualisation of the result by lipiodol has shown the hope to be unjustified, and recently two clinical failures have been reported, whether from the restoration of continuity, the formation of fistula between the peritoneal cavity and the tube somewhere in its course, or the slackening of the ligature. The official German method is based on the experience of A. Döderlein (Munich), who has since 1926 treated 30 cases by the method of Flatau. In this the tube is first rendered free by division of the mesosalpinx; it is then tied on itself in a knot and a silkworm ligature tied not too tightly around this knot. If carefully carried out there is little probability either of the lumen being restored or of any fistula formation. Although there is no mention of it in the German account presumably the possibility exists of restoring continuity if that should prove desirable by removal of the ligature. That has proved to be the case after temporary sterilisation by burying the fimbriated end of the tube beneath the peritoneum.

THE LANCET

LONDON: SATURDAY, JUNE 16, 1934

DIPHTHERIA AND THE HUMAN HERD

A NEW report by Surgeon-Captain S. F. DUDLEY and his colleagues[1] on the results of diphtheria immunisation in Greenwich Hospital School brings to a close a decennium of study of the remarkable epidemiological conditions which have obtained in the Greenwich School. Circumstances allowed of opportunity of observing, without interference, a human herd intensely infected with the diphtheria bacillus and the observers have made the best possible use of the occasion. This intense and continuous survey in relation to infection of a "semi-closed" institution with a population of approximately 1000, has few parallels in the literature of epidemiology. In 1921 permission was obtained to Schick-test Greenwich Hospital School where for some years much anxiety and sickness had been caused by diphtheria. Since then up to the time when Greenwich Hospital School left London in April, 1933, it has been possible to watch the distribution and production of immunity and infection with diphtheria bacilli in the institution. The fact that the authorities permitted Schick-testing from 1921, but withheld permission to inoculate the school against diphtheria until 1928, presented a unique opportunity to study the natural development of antitoxic immunity in a herd in which the diphtheria morbidity was exceptionally high. Had not the authorities banned the employment of anti-diphtheria inoculations it is unlikely that any modern immunologist would have dared to withhold artificial active immunisation in view of the serious drain on the time, health, and finances of the school, and no chance of studying the natural latent immunisation of the school would have occurred. Moreover the acceptance by the school authorities of inoculation against diphtheria in 1928 introduced a variable which allowed a close comparison of natural immunity, acquired by a community in which diphtheria was endemic, with a condition of immunity artificially induced by inoculation. It was found that three doses of diphtheria toxoid can produce in three months as high an immunity as three years' residence in a community where diphtheria is endemic; and further the natural process was necessarily accompanied by a high incidence of diphtheria, whereas artificial immunisation was followed by the almost complete disappearance of clinically recognisable diphtheria.

The intense degree of infection prevailing at the school during the period of observation may be judged from the following facts. During the years prior to the introduction of active immunisation the average number of cases of diphtheria notified per annum was 45. At one time during the survey 13 per cent. of the boys were carriers of the "gravis" type of bacillus, at another time over 30 per cent. of a sample of Schick positive boys became naturally Schick negative within four months. In such an institution latent immunisation proceeds at an extraordinary rate and it is calculated that three years' residence in the school produced as effective an immunisation as the usual prophylactic procedures. It must be emphasised that the natural immunity which was so induced was dearly bought. To every three or four latent immunisations one case of diphtheria occurred. It is generally accepted that in the normal population it is rare to find a Schick positive individual harbouring virulent bacilli without showing symptoms. At the same time if one accepts the "Durchseuchung" theory of the development of natural immunity to diphtheria one must suppose that most Schick positives must at some time or other harbour virulent bacilli. Under the conditions of intense infection at the Greenwich School five virulent carriers were found among 58 Schick positive boys. In this special series Schick positives were not significantly less likely to be carriers of virulent bacilli than Schick negatives. It may be noted, however, that in four out of the five Schick positive carriers, the Schick positive had been preceded by the Schick negative state, and it is likely that the boys had some measure of active immunity even though antitoxin had disappeared from their blood. After the methods of active immunisation had been introduced into the school, the "gravis" type of bacillus replaced the "mitis" as the prevailing type and coincident with this change there was an outbreak of "modified" diphtheria among boys who had been passed as Schick negative. The disease in these boys was mild and was mostly unrecognisable on clinical grounds but cogent reasons can be given for accepting the majority of them as genuine diphtheria. It is interesting to note that the incidence was greater among the artificially immunised than among the naturally immune. The circumstances were such as to put the greatest possible strain on modern methods of prophylaxis and these proved equal to the test.

A conclusion in the report which is likely to arouse controversy is that under certain conditions increase in the number of immunised individuals in a community increases the number of virulent carriers, and *ipso facto* the risk to the Schick positives of the same community. Such a possibility has often been contemplated by students of diphtheria prophylaxis but very little evidence that it is more than a possibility has hitherto been produced. Surgeon-Captain DUDLEY supports his closely sustained argument with observations outside the Greenwich School such as those of E. S. GODFREY, but we question whether these observations really support his contention. Nevertheless in matters of ecology it is recognised that interference in one direction may lead to unforeseen results in another and the provocative views advanced in this report are likely to stimulate investigation. The authors constantly remind us that the conditions at Greenwich were exceptional and what is true of that institution is not necessarily true of others. The key of the situation at Greenwich may perhaps be found by looking at the two photographs that serve as frontispiece to the report. One called "the human herd" depicts the Greenwich boys closely packed at dinner, and the other their grossly overcrowded sleeping quarters. Anyone with a sense of modern social progress might well wonder whether the phrase "the human herd" is here used in a scientific or in ironical sense, but perhaps in this case the meanings are not far apart.

---

[1] Active Immunization against Diphtheria: its effect on the Distribution of Antitoxic Immunity and Case and Carrier Infection. By Sheldon F. Dudley, Percival M. May, and Joseph A. O'Flynn. Medical Research Council. Special Report Series No. 195. London: H.M. Stationery Office. Pp. 140. 3s.

Many who have studied the successive reports of the diphtheria infection at the Greenwich School must have been disposed to criticise the hygienic arrangements of the school. The Governors of the school, like the Pope's mule, have indeed saved up their kick for a number of years but it must be admitted that they have eventually used it to some purpose. Within the last year or two the school has been removed to splendid quarters in the country; it may be anticipated that in its new and ideally healthy environment it will cease to provide such a wealth of material for the study of herd infection. To the practical hygienist the end of trouble is not the least instructive part of it and we hope that the epidemiological history of the school will some day be continued, though it is likely to prove uneventful. It would, we think, complete an excellent commentary on the right and the wrong way of "herding" human beings. Meanwhile for those interested in the broader aspects of epidemiology and herd immunity, as well as those concerned with diphtheria prophylaxis, the report provides a mine of interesting data.

THE DETERMINATION OF POST-MATURITY

THE incidence and dangers of post-maturity of the fœtus are subjects on which writers and teachers of obstetrics are unduly reticent. It is perhaps too readily assumed that, where the calculated date of delivery has long passed, the patient has been inaccurate in recording her last menstrual period or that impregnation has immediately preceded the first missed period. Medical officers working in maternity hospitals have learned to place little reliance upon the statements of patients unless these are corroborated by the results of physical examination, and among such patients there are indeed many reasons why a wrong date for expected delivery may be offered either in good faith or to hide some failure to comply with rules or doctor's orders. Ignoring errors arising from inaccurate information or calculation which can often be corrected by physical findings, it is remarkable how many patients in actual obstetric practice do not spontaneously go into labour on the date which was expected for their delivery. Most of these ultimately produce babies which present the recognised signs of maturity in respect of length, condition of skin, finger nails, absence of lanugo, presence of plentiful vernix caseosa, and, in the male infants, testicles in the scrotum; and where these things are so it may be supposed that one or other of the common explanations will be correct. A few cases of pregnancy of longer than expected duration result in intra-uterine fœtal death which is followed at varying intervals by spontaneous delivery of a macerated fœtus and a placenta which has undergone degenerative changes indicative of senility, such as white infarcts of varying size. Investigation brings to light no explanation of the death of the fœtus beyond the microscopic appearance of the placenta which shows some degree of obliterating endarteritis of the small vessels. In other cases where delivery deemed overdue has occurred spontaneously or after induction of labour, the child at birth shows characteristics which are generally ascribed to post-maturity, the placenta also appearing senile. Such fœtuses are definitely longer than the normal 20 inches. The head is larger in all its diameters, the bones of the vault are harder, so that moulding is slight, and the sutures are narrow, so that overriding is minimal. A large unmoulded head obviously conduces to delay in the second stage of labour, and may result in laceration of the perineal body and even in stillbirth. The classical picture of such a post-mature child is with skin thicker and more opaque than usual, and colour nearer grey than the healthy pink of a normal fœtus at term. Peeling tends to occur all over the body, being especially marked on the palms of the hands and the soles of the feet. As the liquor amnii in these cases is usually green in colour from admixture of meconium, the threads of peeling skin are stained green or greenish-yellow, so that during the first few days after birth the child has a more or less piebald appearance until the peeling is complete. The nails of the fingers and toes extend beyond the tips of the digits. Presumably as a result of a placenta no longer sufficient, the child is usually very thin and its weight is low for the size of its skeletal framework. Whether this is a picture occurring significantly more often in children born after the expected date is not certain. It is at least possible that variations in rate of development occur in individual babies.

The proportion of children born alive after the expected time who show definite signs of post-maturity seems to have been somewhat neglected by those searching the records of maternity hospitals for statistical data, possibly because experience has made them sceptical of expected dates. But all obstetricians can quote cases that have been watched almost throughout the antenatal period and have failed to go into labour at term. When, because of the increasing size of the fœtus and the distress of the mother, pregnancy has been terminated a week or two after the expected date of delivery, a fœtus 20½ to 21½ inches in length has been born. One lying-in hospital records the following patients:—

A private patient whose virginity before marriage was not doubted was found to be 12 weeks pregnant 13 weeks after marriage; quickening occurred at 18 weeks, and engagement of the fœtal head at 36 weeks. Labour took place 34 days after the expected date, when delivery was effected by forceps of a female child weighing 10 lb. and measuring 22½ inches in length. In a second pregnancy labour was induced one week after term and the female child delivered weighed 9¼ lb. and measured 20½ inches. At the third pregnancy labour was induced at term and a mature male child was delivered who weighed 9 lb. and measured 20¼ inches. At the time of induction of the second and third labours the cervical canal was not taken up, and there were no signs of the onset of labour. Another patient gave birth to a female child weighing 7¼ lb. and measuring 21½ inches, born three weeks after the expected date of delivery. Induction of labour in the second pregnancy at term resulted in the birth of a female child weighing 6¼ lb. and measuring 20 inches.

When, whether because of the previous obstetric history of the patient or her present history or physical condition, post-maturity is suspected, the obvious course is to attempt to induce labour medicinally. The method of induction used in these circumstances varies in different clinics; a favourite one consists of the administration of a large dose of castor oil, followed by quinine or intramuscular injections of pituitrin in ♏iii doses at two-hourly intervals to a total of 2 c.cm. If labour fails to start after this treatment, it is highly probable that after all the patient is not at term, and therefore surgical interference would be contra-indicated. It is not, however, the choice of a method of induction that troubles the practitioner, but the determination of the criteria for intervention in any individual patient, and here obstetric literature gives him little help. Careful records of the case-histories of maternity patients among educated women might be of great value in estimating the frequency of pregnancy lasting longer than the expected duration of 280 days. Details of length and weight of fœtuses, with notes on cutaneous appearance and the condition of the placenta, would serve to determine how many of them showed the accepted criteria of post-maturity; and it should be remembered that evidence of stage of development of a fœtus is valueless unless it is supported by records of fœtal length, which is much less variable than its weight. X ray examination of the tibia immediately after birth may reveal a centre of ossification in the upper epiphysis of the tibia, of which the significance will depend on the sex of the child. Generally speaking this centre is manifest in girls before birth, but in boys does not normally appear until four weeks or even longer after birth.

DESENSITISATION FOR HAY-FEVER

Hay-fever is one of those minor maladies which the doctor, if not a sufferer himself, is apt to deal with a little light-heartedly, but which the patient cites as a reproach to the state of medical knowledge. In Germany the patient's protest has taken the form of a Hay-Fever Association which (appropriately enough) holds its annual meeting in the middle of the hay-fever season in some such refuge as the open treeless island of Heligoland. The medical adviser on the association's committee recently published a review[1] of the treatment of hay-fever, concluding with an imposing table—compiled apparently from the records of the association—in which the therapeutic effects of no fewer than 90 drugs and methods of treatment in over 2000 cases are set forth and analysed. He strongly advocates "rational therapy"—i.e., identification of the sensitising pollen by skin-testing (Urbach,[2] of Vienna, prefers the direct intranasal application of pollen extract on a swab) and subsequent desensitisation of the patient.

The German methods and results of desensitisation are critically considered by Hansen,[3] who treats from 300 to 600 cases of hay-fever annually in Lübeck. He finds, by skin-testing, that over 90 per cent. of his patients are sensitive to grass pollens, while from 10 to 20 per cent. of them are sensitive to the pollens of the lime tree and the acacia. His desensitisation follows Walker's method—namely, a series of 20 subcutaneous injections of increasing small amounts of pollen extract (from 0·2 c.cm. of 1 in 1,600,000 to 0·7 c.cm. of 1 in 5000) at three to four-day intervals, timed to end at the opening of the hay-fever season in the latter half of May. Alternatively he sometimes uses an intensive series of daily doses for a month, and sometimes spreads the course throughout the year. This treatment has enabled over 70 per cent. of his patients to run the gauntlet of the pollen season almost or quite without symptoms. In less than 10 per cent. it has failed completely. Hansen attributes some unsatisfactory results to the use of grass-pollen extract only, in patients sensitive to tree pollens as well, and others to inadequate dosage: he is emphatic that the early doses and the increases must both be small, while the final dose attained must be large. A successful desensitisation is seldom permanent, and in most cases the treatment must be repeated annually, at least for several years. Anaphylactic reactions of appreciable severity occurred once in every 300 injections, in the form of immediate shock, urticaria, œdema of the Quincke type, or focal exacerbations, and seemed to be relatively more common in women in the four days preceding menstruation; they were treated by the recognised procedure of applying a tourniquet above the point of injection and giving adrenaline and calcium gluconate. Rice[4] has recently added the refinement of applying a second tourniquet (in the form of a sphygmomanometer cuff) to the opposite arm above the site of injection of the adrenaline; this was done in a patient who had by accident received a gross overdose of pollen extract, and the rates of absorption of both extract and adrenaline could then be nicely controlled in accordance with the resulting symptoms by appropriate short relaxations of the two tourniquets.

[4] Jour. Amer. Med. Assoc., April 14th, 1934, p. 1222.

The experience of these German workers accords well with that of FREEMAN[5] in this country, described in our columns a year ago. Since the hay-fever season is now upon us, it is mostly too late to offer its victims for this year any but symptomatic treatment; but this is the time to assure them that if they will submit themselves to thorough desensitisation under careful and expert supervision, beginning about March, they will have some prospect of comfort next season.

UNEMPLOYMENT AND MENTAL DISORDER

THE number of unemployed people in England is lessening, but they are still an urgent problem in politics and national economy, and, though less obviously, in mental hygiene. It cannot be supposed that men can remain idle and impoverished for long periods without suffering harm to their mental health. If unemployment is considered without regard to this, its effective cure is likely to be delayed, however good the social measures for removing it. No one can tell what proportion of those long unoccupied would be unable for psychological reasons to return at first, or at all, to employment when it became available.

The absence of adequate information about the psychological effects of unemployment is probably due to the understandable reluctance of the unemployed man to submit to minute inquiry into his private life. General impressions are supplied by many people whose work brings them into contact with the problem, but these remain impressions, seldom confirmed by statistics and usually biased by the particular circumstances of the relationship or by the sentiments of the observer. A psychiatrist, for example, sees only those who have developed some form of mental disorder, and he might on inadequate grounds assume that these patients represented a fair sample of the unemployed or that in them unemployment was the main causative factor of their illness. A different but even stronger objection may be made against the use for scientific purposes of first-hand accounts of uncertain provenance. Those contained, for example, in a recently published work entitled "Memoirs of the Unemployed,"[6] are doubtless authentic, and are possibly as typical as the collectors hope; but the described method of collection leaves this uncertain. Such a book is painfully interesting; its anonymous authors tell individual tales of suffering and often of moral deterioration, undeserved and resisted, that cannot but excite sympathetic discontent at our imperfect social order, but they cannot be a basis for defensible opinions on the general physical or mental effects of unemployment. The concluding chapter, by Dr. MORRIS ROBB, shows how easily the observer may be led into dubious induction; a few patients whose mental illness is the selective factor, and second-hand accounts from friends and acquaintances, cannot be regarded as providing adequate material for the assessment he offers of the psychological effects of unemployment.

There is no reason to doubt that discontent, resentment, irritability, anxiety, depression, laziness, and other ills of the spirit commonly go in company with forced unemployment and unfilled leisure; there is no clear evidence for it, but it is probable and understandable. This is, however, by no means true of the morbid heightening of such effects which we see as mental disorder. In a carefully examined series of patients in whom psychosis or psychopathic disturbance of personality is associated with long-standing unemployment, the constitutional factor may be found to be more significant than the social situation in many cases. To say that "unemployment is often the immediate cause of a severe psychic illness" is to be dogmatic on poor grounds; such a causation is demonstrable only in rare instances. There is strong reason to believe that forced unemployment favours the manifestation of mental, as of physical, ill-health in predisposed persons, but in this it is not specific; it acts as do other adverse circumstances, and its importance has not yet been determined by a study of unexceptionable material. Material that is in other regards unexceptionable, such as that in the volume under consideration, does not meet the strict requirements for forming a medical judgment. It may be that general conclusions are here impossible, or that the necessary data are hardly to be collected; well-informed impressions are perhaps the best that can be obtained. In any case, though unemployment is an evil, all will agree, to be combated on medical as on social grounds, it is better to recognise the vagueness of our present knowledge of its effects than to let it be invoked as a cause of manifold mental troubles in much the same way as the war was invoked some years ago.

WALTER FLETCHER

WE publish elsewhere a letter setting forth the unanswerable reasons why a permanent memorial to the services of Sir Walter Morley Fletcher, first secretary of the Medical Research Council, should be instituted. It is signed by persons whose positions, official, scientific, and literary, are such that words in explanation of the authority with which they write would be intrusive, while the suggested form which the tribute to Fletcher's memory should take is admirable. First, they say, the memorial should be personal, and secondly it should be associated with the furtherance of the causes which Fletcher had so much at heart and for which he worked with such devotion and success. With all the signatories Fletcher must have come into close contact personally in Cambridge, London, and the social world, as well as officially, and they set out a simple and eloquent justification of his claims upon the memories of us all. The memorial should be instituted, and in the form suggested; we hope and believe that our readers will share this view, and help to make the movement a large and prompt success.

ANNOTATIONS

TRELOAR HOSPITAL COMPLETED

FOUNDERS' Day at Alton on Monday last gave the patrons of Lord Mayor Treloar Cripples' Hospital their first opportunity of seeing as a going concern the hospital completely rebuilt in bricks and mortar. It is one of the many remarkable features of Alton that for nearly thirty years the pioneer work of the hospital was carried on, and carried on efficiently, in timber structures remaining as a legacy of the South African War. The foundation-stone of the new buildings was laid nearly five years ago and for the last few months all the five new ward blocks have been in use. On Monday there was not a single bed in the wards; all the three hundred children were on the terrace, 984 feet long and 25 feet wide, which joins the five ward blocks and is the last word on sun-and-air treatment in this or indeed any country. Colonel the Hon. Frederick Lawson, chairman of the hospital, who welcomed the guests, including the Lord Mayors of London and Portsmouth, took the unusual course of saying nothing in commendation of the completed scheme, simply asking visitors to see for themselves and draw their own conclusions. The cost to date has been in the region of £150,000, and another £50,000 are required to rehouse the nurses and staff on the same modest but efficient scale, for although the hospital as such is complete, the administration is still suffering from lack of space and out-of-date equipment. During the afternoon the visitors found attraction in demonstrations of treatment in the new light department, of school handicrafts, of the manufacture of splints, and of remedial exercises. In conclusion we may recall a remark made in these columns when the rebuilding was commenced: when complete the Treloar Hospital will have a material framework worthy of the character and spirit of the work carried on within it. Happily that is now the case.

SPECIFIC THERAPY AGAINST TYPE III. PNEUMOCOCCUS

IN studies reported within the past two years O. T. Avery and R. Dubos have described the isolation from a soil bacterium of an enzyme active against the specific polysaccharide of the Type III. pneumococcus. Although the destruction of its capsular polysaccharide does not kill the pneumococcus it appears to render it susceptible to the normal defence mechanisms of the body, since the enzyme protects mice against infection and exerts a curative action on an experimental infection already established. K. Goodner, Dubos, and Avery later showed that a similar curative effect was exerted on rabbits previously infected by the intradermal injection of Type III. pneumococci. The effect of this enzyme, in vitro and in vivo, is, it should be noted, strictly type-specific. It does not attack the polysaccharides produced by other types of pneumococci, nor does it exert any protective or curative effect on infections produced with them. Two further reports from the Rockefeller Institute would seem to increase the probability that this enzyme may prove of service in the treatment of Type III. pneumonia in man. In the first,[1] T. Francis, Jr., and E. C. Terrell describe the production of a typical lobar pneumonia by the intratracheal or intrabronchial inoculation of Type III. pneumococci into Java monkeys (*M. cynomolgos*). The records of these infections are very complete. They include repeated blood cultures, repeated leucocyte counts, and repeated X ray photographs during life, and complete necropsies on those monkeys that died. There can be little doubt that the experimental disease in the monkey is closely similar to the natural disease in man. In the second paper,[2] Francis, Terrell, Dubos, and Avery report the results obtained in the treatment of these experimental monkey infections with the bacterial enzyme. They note the difficulty of obtaining adequate controls, because of the wide variations in the severity of the disease in untreated monkeys; but their results are clearly encouraging. They divide their treated and untreated animals into four groups, according to the severity of the bacteræmia during the first three days of the disease. In the two intermediate groups, with bacteræmia of moderate severity, the treated animals showed a definite advantage over the untreated controls. One of 24 treated monkeys died as against 18 of 32 untreated. In the mild infections there was little opportunity for the enzyme to give evidence of its therapeutic effect. No rabbit died in either group. In the severest cases it appeared to be relatively ineffective in modifying the course of the disease.

BACTERIOLOGICAL ANALYSIS OF WATER

THE tendency towards standardisation of technical procedure in routine analysis is exemplified in the report recently issued by the Ministry of Health on the bacteriological examination of water-supplies.[3] Hitherto every public health laboratory has employed its own technique, and it is not therefore surprising that discrepancies should have occurred in the reports of different analysts on the same samples of water. Where, as in water examination, an essentially quantitative technique is required, it is especially important that all workers should use the same methods; otherwise interpretation must vary from one laboratory to another. On the other hand, it is against the interests of progress to standardise too rigidly; a certain margin of freedom is not only permissible but actually desirable. The committee responsible for the present report [4] seem to have been well aware of this, and have therefore chosen to lay down detailed descriptions of the simple procedures, such as the agar plate count, while allowing a considerable latitude for the determination of the various indices of excretal pollution. An admirable description, likely to be of great assistance to the sanitary inspector, is given of the precautions to be observed and the points to be noted in the collection of samples, and a maximum interval of eight hours between the taking of the sample and the commencement of its analysis is recommended. In the analysis itself the old gelatin plate count is replaced by an agar count at 20–22° C., and most useful information is provided on the ways in which the experimental errors inherent in the plate count may be reduced to a minimum. In the determination of coli one

[4] Dr. T. Carnwath (Ministry of Health), chairman: Dr. M. M. Barratt (assistant bacteriologist, Lister Institute), Dr. John F. Beale (Counties Public Health Laboratories), Mr. H. T. Calvert, D.Sc. (Ministry of Health), Sir Alexander Houston, F.R.S. (late director of water examination, Metropolitan Water Board), Dr. W. M. Scott and Dr. F. R. Seymour (Ministry of Health), Mr. A. F. Standfast, Dip. Bact., and Prof. G. S. Wilson (respectively research worker and professor of bacteriology, London School of Hygiene and Tropical Medicine).

50 ml., five 10 ml., five 1 ml., and in certain samples five 0·1 ml. quantities of water are to be examined; and to avoid the customary but most unsatisfactory way of issuing the report as "Present in 10 ml., absent from 1 ml.," tables are provided, calculated from a formula based on the theory of probability, by which the most probable numbers of coli in 100 ml. can be determined. The further differentiation of coli into the fæcal coli, the intermediate, and the aerogenes-cloacæ types is made contingent on the probable number of organisms giving the presumptive coli reaction. Here the committee are very diffident in expressing an opinion. They suggest, however, that if less than two coli are present in 100 ml., the water is of sufficiently high standard to render differentiation unnecessary; again, if ten or more coli are present, the water is probably so bad that differentiation is waste of time. If, however, there are between two and ten coli per 100 ml., it is advisable to ascertain the proportion of the different types present. If they prove to be mainly fæcal coli, the water is condemned; if, on the other hand, they are mainly of the intermediate or aerogenes type, no immediate steps towards improving the source of supply need be contemplated. Appendices contain a description of the standards to which apparatus should conform, and of the preparation of the media that are recommended in the text. The report will be welcomed by all who are engaged both in the analytical and the administrative control of water-supplies.

NERVOUS COMPLICATIONS OF MUMPS

THE nervous complications which may precede, accompany, or follow an attack of mumps are varied and striking but fortunately rare. C. B. McKaig and H. W. Woltman[1] report the occurrence of myelitis, of which they can find only one other example in the literature, and take occasion to review the other nervous sequelæ. Their case of myelitis occurred in a girl of 16 years on or about the fourteenth day after an attack of mumps from which she had apparently recovered completely. General malaise and prostration lasting some hours was followed by intense pain between the shoulder-blades. Thereafter symptoms and signs of transverse myelitis at the level of the sixth cervical segment developed, although the subsequent course of the case led the authors to think that there was also extensive destruction of the cord below the level indicated. McKaig and Woltman consider that encephalitis is probably the gravest complication to be feared, although recovery is the rule and residual troubles for the most part clear up eventually. Meningitis may precede the parotid swelling but more commonly makes its appearance within the first two weeks after the attack, though according to A. Wallgren[2] it may be the sole manifestation of infection. The course of mumps-meningitis is benign. Lymphocytosis is the most constant finding in the cerebro-spinal fluid. Discussing neuritis and polyneuritis, McKaig and Woltman express the view that the lesions are more likely to be secondary to meningitis rather than to arise in the peripheral distribution of the affected nerves and that therefore the term meningo-radiculitis would be more appropriate. There are, however, several cases on record of flaccid paralysis of all four limbs associated or not with other paralyses. Although complete recovery is the rule, one case is reported of a fatal terminal bilateral diaphragmatic paralysis which followed mumps-tetraplegia in a woman aged 37.

Paralyses of the Duchenne-Erb and Aran-Duchenne type have also been recorded. Th. Merrill[3] describes a case of mumps in a woman of 65 in whom the right parotid only was affected and was not greatly swollen. The initial symptoms which persisted throughout the attack were severe earache and deafness. Ultimately the 2nd, 3rd, 7th, 8th, and 9th cranial nerves on the right side were involved, giving rise to characteristic paralyses which lasted for two months before disappearing completely. On the other hand, according to McKaig and Woltman, deafness following mumps is usually complete and permanent. Fortunately it is unilateral in three-quarters of the cases, occasionally on the side opposite to the parotitis. The onset is rapid and may be accompanied with tinnitus and vertigo; the usual explanation is that a sudden exudate into the labyrinth has occurred. Mental disturbances in mumps are uncommon but may coincide with the onset of orchitis when they usually take the form of violent delirium lasting a few days. Psychoses such as hallucinations and depressive mania have also been reported. Many years ago M. H. Gordon[4] showed that the causal agent of mumps was a filtrable virus and recently C. D. Johnson and E. W. Goodpasture[5] have confirmed this; but it is not definitely known whether the same agent is responsible for both the parotitis and the nervous manifestations, or whether the latter arise as a result of activation of a virus already present in the nervous system. McKaig and Woltman note in this connexion that the results of serial and repeated spinal punctures suggest the involvement of the nervous system in most cases of mumps and that nervous symptoms may precede the parotitis.

COÖRDINATION OF MEDICAL RESEARCH IN EAST AFRICA

THE various services concerned with medical, veterinary, and agricultural problems in the East African Territories have in the past worked more or less independently, and there has thus been considerable overlapping and duplication of effort. Now, thanks partly to improved communications by air which have brought the administrative centres within a few hours of each other, coördination is progressing. Advantage has been taken of the periodical meetings of the Governors to arrange a series of technical conferences. So far four have been held, devoted respectively to the tsetse fly and trypanosomiasis, to general medical problems, to veterinary matters, and to agriculture. Other meetings are being arranged and it is hoped that they will become annual fixtures. The recently published report of the conference on general medical research shows the advantage of pooling information and of measures to ensure personal contact between officers engaged in various branches of work. Not the least important feature is the subdivision of labour by the allotment of special subjects for inquiry to areas and laboratories best equipped for their study. The conference, which was held at Entebbe, lasted three days and was attended by delegates from Kenya, Uganda, Tanganyika, Nyasaland, and Zanzibar. The administration of the Belgian Congo was represented by Dr. Luc Fontana, director of medical services for the Eastern Province. Dr. W. H. Kauntze, director of medical services in Uganda, presided, and the members of the conference included the directors of the Kenya and Tanganyika services and experts in bacteriology, pathology, medical entomology, biochemistry, and veterinary medicine from the various territories. The presence of the veterinarians proved of great assistance, and it was agreed to invite to future meetings representatives of other allied technical services. Among the subjects proposed for study is the basal metabolism of the African. Little is known about this at present, and the extensive inquiries which have been made into dietetics in the native have been founded upon the basal metabolism of the European. A general inquiry is also to be made into the incidence of malignant disease, particularly the site and histology of tumours. Research is to be carried out on anæmia which is said to be almost universal in the indigenous population. Here again only European standards are available for comparison.

The bacteriology of water-supplies, the study of native foodstuffs, and rural sanitation are in the programme, and there are to be special investigations of malaria, dysentery, tuberculosis, and helminthiasis. The veterinary staff will collaborate in several of these inquiries. A valuable outcome of the conference has been an arrangement for the interchange of sera between the laboratories to ensure comparable results, notably in yaws and syphilis. It is proposed to circulate quarterly interim reports of the work in progress at different centres and there is little doubt that these reports will provide a valuable stimulus to research.

ABSORPTION OF FLUID FROM THE PLEURAL CAVITIES

WITH a view to gaining knowledge of the effect of certain factors on the absorptive activity of the pleura, R. C. Brock[1] has carried out a series of experiments on the rabbit which possesses a mediastinum more stable and impermeable than that of many animals. He used intravenous nembutal anæsthesia and studied the effect on pleural absorption of: (1) the amount of fluid in the cavity; (2) the depth of respiratory movement; (3) inflammation of the pleural membrane; (4) the coincidence of pneumothorax. Rapidity of absorption was measured in every case by injection of a fluid containing a lethal dose of strychnine in a known volume. It was found that the more quickly the animal died the more rapid had been its absorption of the lethal dose. By withdrawal of the fluid remaining in the pleural cavity after death it was possible to prove that the volume absorbed had, in fact, been that which contained a fatal dose. Absorption rate was quicker with increase of the amount of fluid, and with increase in the depth of the respiration. If two rabbits each receive injections of 50 c.cm. of the strychnine solution the one to which CO_2 is administered dies twice as quickly as the other. When a large amount of fluid is present and the respiration is deep and laboured, Brock finds that absorption, and, therefore, death, occurred at a surprisingly rapid rate. Laboured respiration produces its effect, he believes, by increasing the circulation in the pleural vessels. Injection of a few minims of turpentine produced an intense serofibrinous reaction of the pleura within twenty-four hours. The effect of this inflammation was to hasten absorption; death from the strychnine solution was three times as rapid. This was not due to increased sensitivity of the sick animal, since a lethal dose injected into the sound side in an animal with unilateral acute pleurisy caused death no sooner than a corresponding dose in a healthy animal. It is clear that inflammation definitely increases the rate of absorption, and this is attributed to the increased vascularity. The death of these animals from absorption of strychnine solution from their pleural cavities answers the question sometimes raised whether absorption is possible while fluid is being actively poured out by the pleura. The accumulation of fluid in pleurisy is evidently to be accounted for by the excessive rate of its excretion, and not by failure of absorption on the part of the inflamed membrane. Contrary to the result expected, the presence of a pneumothorax at least doubled the rate of absorption. Brock's remark that "the patient who is grossly dyspnœic with a large pyopneumothorax, and an acutely inflamed pleura is absorbing toxins at an alarming rate," sums up the clinical application of his observations.

The clinical bearing of these results is discussed. The factors influencing the absorption of fluids from the pleural cavities is of importance, since it may be of great advantage to a patient that disappearance of a large chronic effusion should be hastened, and still more valuable would be knowledge that would enable us to control the processes at work in an acute empyema. Pyothorax of the synpneumonic type has quite often, temporarily at least, to be left undrained, because the condition of the underlying lung precludes operative interference. Meanwhile the patient may be absorbing micro-organisms and toxins. Brock draws from his experimental results the conclusion that during the course of an acutely infected pleurisy aspiration should be repeatedly practised to diminish the total volume of fluid. Aspiration twice daily is not too much, and will have the added advantage of relieving dyspnœa. The replacement of fluid by a *smaller* quantity of air will, he thinks, do little harm, whereas the *addition* of air to fluid already present will definitely increase absorption. Where the aim is to aid absorption, replacement of fluid by a larger amount of air and giving the patient CO_2 to inspire is logical treatment.

THE DANGERS OF CARBON BISULPHIDE

IT is not generally realised that carbon bisulphide is not only unpleasant in smell but noxious. Workers exposed to its vapour even in small quantity over some weeks or months are liable to symptoms of ill-health of which the first to appear are nausea, indigestion, headache, and giddiness, sometimes accompanied by emotional disturbances which may frankly be hysterical in character. The breath has a characteristic odour, the tongue is pale and flabby, and the face is pale. An appearance of anxiety with sweating of the hands and forehead suggest mild absorption; with continued exposure the disturbance increases and is accompanied by impairment of memory, mental dullness, and depression. The speech may be affected and later there occurs a contraction of the visual fields with diminution of the power of accommodation. In acute poisoning, following exposure to high concentrations over short periods, the symptoms are those associated with acute mental disturbance and, in some cases, acute mania. A memorandum just issued[1] from the Home Office calls attention to these symptoms which should be watched for in persons working in artificial silk or viscose paper works, rubber works, or places where carbon bisulphide is made or may be used.

It is poisonous in concentrations of about 1 in 3000

ABSORPTION OF FLUID FROM THE PLEURAL CAVITIES

WITH a view to gaining knowledge of the effect of certain factors on the absorptive activity of the pleura, R. C. Brock[1] has carried out a series of experiments on the rabbit which possesses a mediastinum more stable and impermeable than that of many animals. He used intravenous nembutal anæsthesia and studied the effect on pleural absorption of: (1) the amount of fluid in the cavity; (2) the depth of respiratory movement; (3) inflammation of the pleural membrane; (4) the coincidence of pneumothorax. Rapidity of absorption was measured in every case by injection of a fluid containing a lethal dose of strychnine in a known volume. It was found that the more quickly the animal died the more rapid had been its absorption of the lethal dose. By withdrawal of the fluid remaining in the pleural cavity after death it was possible to prove that the volume absorbed had, in fact, been that which contained a fatal dose. Absorption rate was quicker with increase of the amount of fluid, and with increase in the depth of the respiration. If two rabbits each receive injections of 50 c.cm. of the strychnine solution the one to which CO_2 is administered dies twice as quickly as the other. When a large amount of fluid is present and the respiration is deep and laboured, Brock finds that absorption, and, therefore, death, occurred at a surprisingly rapid rate. Laboured respiration produces its effect, he believes, by increasing the circulation in the pleural vessels. Injection of a few minims of turpentine produced an intense serofibrinous reaction of the pleura within twenty-four hours. The effect of this inflammation was to hasten absorption; death from the strychnine solution was three times as rapid. This was not due to increased sensitivity of the sick animal, since a lethal dose injected into the sound side in an animal with unilateral acute pleurisy caused death no sooner than a corresponding dose in a healthy animal. It is clear that inflammation definitely increases the rate of absorption, and this is attributed to the increased vascularity. The death of these animals from absorption of strychnine solution from their pleural cavities answers the question sometimes raised whether absorption is possible while fluid is being actively poured out by the pleura. The accumulation of fluid in pleurisy is evidently to be accounted for by the excessive rate of its excretion, and not by failure of absorption on the part of the inflamed membrane. Contrary to the result expected, the presence of a pneumothorax at least doubled the rate of absorption. Brock's remark that "the patient who is grossly dyspnœic with a large pyopneumothorax, and an acutely inflamed pleura is absorbing toxins at an alarming rate," sums up the clinical application of his observations.

The clinical bearing of these results is discussed. The factors influencing the absorption of fluids from the pleural cavities is of importance, since it may be of great advantage to a patient that disappearance of a large chronic effusion should be hastened, and still more valuable would be knowledge that would enable us to control the processes at work in an acute empyema. Pyothorax of the synpneumonic type has quite often, temporarily at least, to be left undrained, because the condition of the underlying lung precludes operative interference. Meanwhile the patient may be absorbing micro-organisms and toxins. Brock draws from his experimental results the conclusion that during the course of an acutely infected pleurisy aspiration should be repeatedly practised to diminish the total volume of fluid. Aspiration twice daily is not too much, and will have the added advantage of relieving dyspnœa. The replacement of fluid by a *smaller* quantity of air will, he thinks, do little harm, whereas the *addition* of air to fluid already present will definitely increase absorption. Where the aim is to aid absorption, replacement of fluid by a larger amount of air and giving the patient CO_2 to inspire is logical treatment.

THE DANGERS OF CARBON BISULPHIDE

IT is not generally realised that carbon bisulphide is not only unpleasant in smell but noxious. Workers exposed to its vapour even in small quantity over some weeks or months are liable to symptoms of ill-health of which the first to appear are nausea, indigestion, headache, and giddiness, sometimes accompanied by emotional disturbances which may frankly be hysterical in character. The breath has a characteristic odour, the tongue is pale and flabby, and the face is pale. An appearance of anxiety with sweating of the hands and forehead suggest mild absorption; with continued exposure the disturbance increases and is accompanied by impairment of memory, mental dullness, and depression. The speech may be affected and later there occurs a contraction of the visual fields with diminution of the power of accommodation. In acute poisoning, following exposure to high concentrations over short periods, the symptoms are those associated with acute mental disturbance and, in some cases, acute mania. A memorandum just issued[1] from the Home Office calls attention to these symptoms which should be watched for in persons working in artificial silk or viscose paper works, rubber works, or places where carbon bisulphide is made or may be used.

It is poisonous in concentrations of about 1 in 3000 of air and dangerous in concentrations of 1 in a thousand. It is moreover very volatile, boiling at 46° C., and yielding a vapour which will fire at 125–135° C.—not very much above the boiling point of water. The flash point of the liquid is below minus 20° C. Most chemists who have used carbon bisulphide as a laboratory solvent have experience of the readiness with which it will ignite when only ordinary precautions are taken, and of the choking smell of the sulphur dioxide produced when it burns. A liquid which easily yields a highly poisonous and inflammable vapour and a poisonous product of combustion is, clearly, a source of danger to those who use it, and compulsory notification of carbon bisulphide poisoning in accordance with the order of the Secretary of State of Dec. 31st, 1924, is obviously a wise precaution.

EVIPAN AND ASTHMA

SINCE evipan is at the present time finding great favour, particularly for use on patients whose respiratory mechanism is at fault, its effect in a case reported in the *Münch. medizin. Wochenschrift* of Feb. 16th (p. 257) is noteworthy. The patient was a woman of 39, a subject of pulmonary tuberculosis and of asthma, on whom it was desired to perform a short gynæcological operation. Evipan in a 3 c.cm. dose was injected over a period of six minutes—i.e., at a rate slower than usual. The respiration came to a standstill and it was only after intravenous injection of 10 c.cm. coramine and the performance of artificial respiration that it was restarted after some minutes. That the author, Dr. P. Feldweg, regards this experience as a warning against the use of evipan on asthmatic subjects is made clear in the significant title of his article, "Bei Asthma kein Evipan"!

CONFERENCE ON VITAMIN STANDARDISATION

AN international conference on vitamin standardisation is being held this week at the London School of Hygiene and Tropical Medicine, under the auspices of the Permanent Commission on Biological Standardisation of the Health Organisation of the League of Nations. The following are taking part in the Conference, over which Prof. E. Mellanby is presiding: Prof. J. C. Drummond (University College, London); Prof. H. V. Euler (Stockholm); Prof. L. S. Fridericia (Copenhagen); Prof. B. C. P. Jansen (Amsterdam); Prof. P. di Mattei (Pavia); Prof. E. M. Nelson (Washington, D.C.); Prof. E. Poulsson (Oslo); Madame L. Randoin (Paris); Prof. H. Steenbock (Wisconsin); Prof. A. Szent-Györgyi (Szeged); with Dr. W. R. Aykroyd (League of Nations, Geneva) and Miss H. Chick, D.Sc., Technical Secretaries. The following are attending the Conference as observers: Dr. M. H. Brown (Connaught Laboratories, University of Toronto); Miss K. H. Coward, D.Sc. (Pharmaceutical Society of Great Britain); Mr. P. Hartley, D.Sc. (National Institute for Medical Research); Dr. Lormand (Laboratoire National de Contrôle des Médicaments, Paris); Dr. Mendez (Instituto Tecnico de Farmacobiologie, Madrid); Dr. M. Tsurumi (Japanese Delegate to the Health Committee of the League of Nations); Dr. A. Jung (University of Bâle). This Conference is the second of its kind. The first Conference, held in 1931, established standards and units for vitamins A, B, C, and D, which have since been widely used in many countries throughout the world. Although the standards originally recommended have on the whole worked well, the rapid advance of scientific work in this field has made it necessary to review th findings of the first conference in the light of recentl acquired knowledge. Several vitamins are no available in a relatively pure state, and it is probabl that the present conference will recommend th replacement of the standards chosen in 1931 b purer preparations than were available at that date especially in the case of vitamins C and D.

ADRENAL DENERVATION

Dr. Crile is now able to summarise [1] no less tha 308 cases in which denervation of one or both of th suprarenal glands has been carried out. He find that the unilateral operation, performed in 52 cases is followed by no ill-effects but is less effective tha the bilateral; the latter, however, is occasionall followed by attacks of vomiting and diarrhœa. Hi 308 cases include 76 of neurocirculatory astheni (hyperadrenalism), 79 of hyperthyroidism, 37 o peptic ulcer, 40 of epilepsy (in some of which adrena lectomy was done), and a few of diabetes. Th clinical results are stated to be good. Of the patient with neurocirculatory asthenia, 87 per cent. wer cured and 7 per cent. improved. Of those wit hyperthyroidism, 95 per cent. were cured. Th treatment advocated for the majority of thyrotoxi patients is thyroidectomy, adrenal denervation bein reserved for those with residual or recurrent hyperthyroidism. In the cases of peptic ulceration, it i stated, cure followed in 93 per cent. and improvement in 7 per cent., and Crile does not hesitate t recommend the operation when the customar medical and surgical treatment has failed. Of th epileptic patients, 33 per cent. are described a improved or cured. Adrenal denervation is held t be contraindicated in established cases of hypertension, and has proved useless in Raynaud's diseas and scleroderma. The series included two deaths both due to serious injury to the adrenal glands.

AFTER discussing many aspects of medical education (see report on page 1306) the General Medical Council appointed a Curriculum Committee with the following membership: Dr. H. L. Tidy (chairman); Prof J. B. Leathes; Prof. J. S. B. Stopford; Sir George Newman; Dr. H. G. Dain; Prof. L. P. Gamgee; Prof. R. J. Johnstone; and the president ex officio. This committee is to consider information and proposals received by the Council with respect to the revision of the curriculum, and to report to the Council.

THE Albert medal of the Royal Society of Arts for 1934 has been awarded to Sir Frederick Gowland Hopkins, president since 1930 of the Royal Society, "for his researches in biochemistry and the constituents of food." This medal was instituted in 1862 as a memorial to the Prince Consort, sometime president of the Society, and is awarded annually for distinguished merit in promoting arts, manufactures, or commerce.

A DISCUSSION on the Nature of Sex and its Sociological and Legal Implications will take place in the section of obstetrics and gynæcology of the Royal Society of Medicine on Friday, July 6th, at 8.15 P.M., and the members of the Medico-Legal Society have been invited to take part. Sir Bernard Spilsbury, president of the Medico-Legal Society, and Lord Riddell will, it is hoped, join in the discussion.

PROGNOSIS

A Series of Signed Articles contributed by invitation

VI.—PROGNOSIS IN JUVENILE RHEUMATISM*

In juvenile rheumatism the disease of the heart arditis) is not only the sole cause of death, but the ly manifestation of the infection which may lead permanent damage. All the other lesions clear completely. Persistent joint disease is not a quel to acute rheumatic arthritis. Subcutaneous odes may linger long before they disappear. Even orea, though it may last off and on, more or less, r two years or more, or may be subject to relapses r several years, will, if the child survives, ultimately bside, leaving much the same type of nervous stem as before its development. It may, however, appear later during pregnancy.

We are, therefore, mainly concerned with the rognosis in rheumatic heart disease in young subects ; and it is well recognised that nothing like ccuracy in this matter can be attained owing to one pecial factor—namely, the great tendency shown by ll rheumatic children to develop recrudescences of heir infection. The heart of a child, once compensation is established, never deteriorates, still less breaks own, from mere mechanical overstrain ; it is always resh infection that turns the scale against it. And he same is true to a far greater extent than is generally ecognised in the rheumatic heart disease of adults.

Thus, when considering prognosis in juvenile heumatism, we have first to discuss the liability to uture reinfections. But before going into detail, ince the outlook differs very materially in cases n which the heart disease is mild and those in which t is severe, it is necessary to describe in what sense hese terms are to be used here. In the *mild* class nay be grouped cases showing tachycardia without bvious heart defect ; those showing mitral incompetence with only moderate enlargement of the left ventricle ; and those showing an apical mid-diastolic bruit with or without a mitral regurgitation of moderate degree. In the *severe* group may be included hearts that have suffered from serious pericarditis (and seldom is it anything less than serious), and those showing mitral incompetence with considerable ventricular enlargement (the apex-beat being an inch or more outside the nipple line), or complicated by the presence of aortic regurgitation or pericardial adhesions. Mitral stenosis, fully developed, is a rarity in childhood ; it must be classed amongst the severe cases.

Liability to Fresh Rheumatism and Carditis

It is agreed that juvenile rheumatism is overwhelmingly a disease of hospital, as opposed to private consulting, practice ; and environmental factors play so great a part in its production (or unmasking) that we can only act on the assumption that no rheumatic child, living in its own home and attending compulsorily an elementary day-school, is ever free of the danger of relapse. Nor, unfortunately, will prolonged sojourn in ideal surroundings away from home ensure it against serious relapses on its return to its original environment. But although this is undoubtedly true, experience teaches us that there are large numbers of rheumatic children in whom the outlook is quite favourable. To what proportion of the whole rheumatic child population this applies depends on whether we include such early and slight cases as are seen in a rheumatism supervisory centre or outpatient department, or think only in terms of rheumatic in-patients ; for it is the early and slight cases that do well, and the severe and advanced cases that do badly. Nor is this altogether the trite saying that at first glance it appears to be, for it connotes that it is not as a rule the cases in the mild group which deteriorate to become the cases of the severe group. For some years now it has been my experience that when a really severe case of rheumatic heart disease, the so-called cardiac cripple, comes under observation it is rarely a child whom one has had under care previously ; on the contrary, it is nearly always the case that such a child comes first under observation with its heart irreparably damaged.

MILD GROUP

Supervising a large number of rheumatic children whose hearts are unaffected or only slightly diseased, it is gratifying to watch how well most of them do. It is exceptional for them to suffer from such relapses as require in-patient treatment ; and it is still rarer for them to develop serious heart disease. In a few instances aortic regurgitation may develop, often insidiously ; and occasionally the signs of mitral stenosis may supervene, but this lesion may be largely the result of healing rather than fresh inflammatory processes. In children who have been through one or two attacks of rheumatism (in-patient type) without developing persistent heart disease the outlook is likewise good, and it is uncommon for them to acquire such heart trouble in any further relapses which they may have. Personally, I think too that in these early cases the enucleation of septic tonsils has its best chance to safeguard rheumatic children from the more serious forms of their disease. The operation will not necessarily prevent reinfections set up by epidemic hæmolytic streptococcal sore throats, since in these the lateral walls of the pharynx may be severely attacked ; but in my opinion it prevents the spontaneous attacks of tonsillitis to which rheumatic children are so prone, and renders carditis less frequent and convalescence cleaner and less prolonged. In this large group of rheumatic children, with at most only the milder form of heart disease as defined above, the outlook is favourable, and it is to be hoped that the supervision and periodic re-examination given at a rheumatism centre are factors in producing this happy result. They do quite well remaining at home and attending school. For the worst of them the schools for physically defective children are invaluable ; partly owing to their own régime, partly owing to the escape from the harmful effects of compulsory attendance at an ordinary elementary school. Special care should be taken of the children during the winter months and after epidemic catarrhs, scarlatina, and diphtheria. Holidays should be spent when possible with relatives in the country rather than at convalescent or holiday homes, which are rarely suitable for rheumatic children.

SEVERE GROUP

In the class with severe heart disease the outlook is, as might be expected, much worse than in the

---

Wilkie, April 7th ; Prognosis of Diabetes in Children by Dr. R. D. Lawrence, April 14th ; Tuberculous Laryngitis by Mr. Harold Barwell, April 21st ; Prognosis in Enlargement of the Prostate by Prof. C. A. Pannett, April 28th ; and Prognosis in Eczema by Dr. Henry MacCormac May 5th.

group already described. Compared with the milder group they are still more prone to reinfections; such relapses rarely fail to affect the heart, and often fresh carditis is almost the sole feature of the reinfection. In addition, in the worst cases, the heart deteriorates insidiously between the obvious recrudescences. Epidemic catarrhs frequently set up serious carditis, which is one reason against massing such children together for treatment. Tonsillectomy, although it may lead to improved general health, is far less successful in preventing fresh attacks of carditis than in the milder and earlier cases.

In these two groups of rheumatic children, the mild and severely affected, the outlook is very different. In both groups there are exceptions. In the second group there are not a few instances in which the tendency to relapse subsides, and the ultimate result is more satisfactory than could have been anticipated. In the milder group the number of exceptions is small, and it is rare to watch this type of case go steadily to the bad.

Static Cases

Fortunately there are many children who, although acquiring heart disease in an early attack, cease to develop any further attacks. It is not possible to be sure in which instances this will happen; but, very roughly, such a favourable course is predisposed to by good social environment, a quick return to good constitutional health, and absence of tonsillar sepsis. In these circumstances the youth of the patient, combined with the freedom of the coronary arteries from disease, tend to make the myocardial compensation extraordinarily efficient and capable of carrying on without trouble to late middle age or longer. In about one-quarter of the cases of established mitral regurgitation of mild type, the heart will make a complete recovery within five years. Aortic regurgitation, once established, is permanent.

Fatal Cases

Deaths during childhood are rare in acute rheumatism. Occasionally the infection, even a first attack, will overwhelm a child, and pericarditis may kill even in a few days. In another group the fatal issue can be long foretold. Such children usually show severe pericardial adhesions, and as the years pass the child's periods in hospital become more prolonged and its times at home shorter, until somewhere between the ages of 12 and 18 renewed carditis causes death. I have known several such children to fall down dead although not thought to be in any particular danger at that moment.

In a third group the outlook is much more uncertain. The child, who has severe heart disease and usually a history of pericarditis, develops relapse after relapse; and then unexpectedly an attack develops which gets altogether out of hand, and after a long spell of fever the child succumbs. Subcutaneous nodules may be a feature in such a case, and pericarditis is almost invariably present, although, owing to repeated past attacks, the pericardium is so abnormal that no friction may be audible. Such cases deserve the clinical title of malignant rheumatic carditis; true pathological malignant infection, supervening on a rheumatic valvulitis, is a rare fatal sequence in childhood.

THE PREVENTIVE ASPECTS OF MEDICINE

A Series of Lectures in progress at King's College Hospital Medical School

XXV.—PUBLIC AGENCIES WHICH EXIST FOR THE PREVENTION OF DISEASE

(*Concluded from p. 1247*)

The Health of Children and of Expectant, Parturient, and Nursing Mothers

THE most remarkable development in public health work this century has been the establishment of the maternity and child welfare and the school medical services. So far as the reduction of infantile mortality is concerned, the former has scored a great success. A rate of infantile mortality in England and Wales of 132 deaths per 1000 births 30 years ago is now, in 1933, only 64. There are, however, disappointments; one is that maternal mortality is still far too high and shows little tendency to reduction, and another is that neonatal mortality (deaths under one month) is almost as intractable. The local authorities who administer these services may be either the county councils or the district councils and sometimes a district council administers the maternity and child welfare service and the county council, the school medical service. The latter is always, however, controlled by the education authority of the area, which may be the county or the district council. county boroughs, of course, administer both services.

An important part in the supervision of the welfare of expectant and parturient mothers is exercised by midwives, who, in some parts of the country, are responsible for 80 per cent. or even 90 per cent. of the deliveries. The work of the midwives is supervised by inspectors of midwives appointed by the local supervising authorities under the Midwives Acts—i.e., the county and county borough councils and a few of the largest district authorities.

The Central Midwives Board make rules for regulating the conduct of midwives and any serious breach of the rules is reported to the Board by the local supervising authority. The case is heard by the Board and the name of the midwife may be removed from the roll. Under the rules of the Board the midwife must summon a doctor in the event of certain specified complications arising or if progress is unsatisfactory. In these circumstances the local supervising authority pay the doctor's fee in accordance with a scale prescribed by the Ministry of Health. The local supervising authorities are responsible for prosecuting at the local police-court any uncertified person who delivers women in childbirth except in emergency or under the personal direction and supervision of a registered medical practitioner.

For the purpose of reducing maternal mortality and morbidity, most maternity and child welfare authorities now provide antenatal clinics, maternity homes or hospitals, and postnatal clinics. They supply "home helps" to assist in the domestic work of the house during the mother's confinement. Sterilised dressings, extra nourishment for necessitous expectant and nursing mothers, provision of the midwife's fee in cases of necessity, services of a consulting obstetrician and bacteriologist, particularly in cases of puerperal pyrexia or puerperal fever, hospital treatment or home nursing for puerperal fever or pyrexia or ophthalmia neonatorum are also provided. In fact, there is complete provision for the welfare of expectant, parturient, and nursing mothers.

Though it has often been discussed there is no compulsory notification of pregnancy, though, in a few places, there is a scheme of voluntary notification by a midwife. In practice, most expectant mothers of the class which needs help from a local authority notify themselves by attending the local authority's antenatal clinic or by letting the health visitor know when she happens to be in the vicinity. But with regard to the fact of birth, there is compulsory notification within 36 hours of its occurrence to the medical officer of health, and this is in addition to registration within six weeks of birth by the registrar of births.

This notification has been obligatory since 1915, and imposes the duty not only upon the attendant at the birth but also on other persons present in the house. The purpose of the notification is to enable the health visitor who receives the notification from the medical officer of health to know where her services are required. Her duty is to visit the mother and to give her such advice as is necessary with regard to the upbringing of the child. She visits at regular intervals up to the end of the second year, and in many areas until the child is 5 years of age or has started school and comes under the medical supervision of the school medical service.

The maternity and child welfare authorities also provide infant welfare centres to which mothers bring their children for regular weighing and inspection by a doctor. These centres are not for sick children but for the purpose of keeping healthy children healthy. If they are sick they are referred to a private doctor or to a dispensary or hospital.

There are now 2783 infant welfare centres in England and Wales. Free milk is provided for necessitous children and dried milk is often sold at cost price. The main function of these centres is educational and, in addition to the individual instruction of the mothers, class teaching and lectures are given. There is a home nursing service in connexion with most maternity and child welfare schemes. It is generally given by district nurses and is available for cases of measles, whooping-cough, epidemic diarrhœa, and other specified conditions.

THE SCHOOL MEDICAL SERVICE

The school medical service had its origin in 1907, though Bradford, London, and other places had started such a service a little earlier. It affords the only example of routine medical inspection of a definite and important section of the community. All elementary school-children are subjected to routine medical inspections at entrance to school, at age 8, and at age 12. In London there are four routine inspections, at entrance, at ages 7 and 11, and just before the child leaves school at the age of 14 years.

In addition, the children are examined by a *school nurse*, primarily to ensure cleanliness of the head and body, two or three times a year. She notes any abnormality and refers such cases to the school doctor for special examination. Some 18 per cent. of the children are found, at routine medical inspections, to require treatment for some disease or defect apart from dental caries or lack of cleanliness.

School clinics.—It was soon found that facilities for treatment, either by private doctors or at hospitals, were inadequate, and these clinics were therefore established, of which there are now 1855. They deal mainly with minor ailments (impetigo, sore eyes, and so forth), prescription of spectacles, removal of adenoids and enlarged tonsils, ionisation treatment of otorrhœa, and X ray treatment of ringworm. The children are also inspected regularly by dentists, and dental treatment is afforded at the clinics. At some clinics orthodontic treatment is provided. A small charge is made for treatment (except for the prescription of spectacles) at school clinics, but it is remitted in necessitous cases.

The maternity and child welfare and school medical services also provide an orthopædic service with a view to the prevention of crippling. This includes, in most areas, hospital treatment and the provision of orthopædic clinics where treatment is given by massage, electrical treatment, and remedial exercise.

Most school medical authorities also provide special clinics for rheumatism. All cases of rheumatism, chorea, and rheumatic carditis are kept under close supervision, and, where necessary, hospital treatment is arranged.

Though the above is a broad outline of the duties of a school medical department, it carries out many other functions of a preventive character. For example, questions of school lighting and ventilation are considered, open-air schools are provided for the debilitated, and sight-saving classes for myopes and others who are partially blind. There is also a highly developed system of physical training. Necessitous school-children receive free meals in school and there are many voluntary milk clubs. There is also medical inspection in secondary schools. There can be no doubt that the school medical service is a most potent agency for improving the national physique.

Control of Tuberculosis and Venereal Diseases

Prior to the introduction of the National Health Insurance scheme in 1911 the efforts of public health authorities to deal with *tuberculosis* had been confined to notification in a few areas and to the provision of a few beds. There were, however, many cases of tuberculosis in the poor-law hospitals or in the sick wards of the workhouses. It was recognised that tuberculosis would be a serious drain on the finances of any insurance scheme which provided payment during incapacity for work and a special benefit called "sanatorium" benefit was provided in the Act. A committee was appointed under the chairmanship of the present Lord Astor to advise the government on what measures should be taken to combat this disease.

This committee recommended that an organisation should be set up which would deal with all cases of tuberculosis independently of whether they were insured under the National Health Insurance scheme or not, though, in fact, the arrangements for the treatment of the insured in sanatoria and tuberculosis hospitals remained under the Insurance Committees until 1921. To put it in the words of the committee, the scheme is intended—

> "to complete existing public health administration in respect of tuberculosis, and is based on the establishment and equipment of two units related to the general public health and medical work carried on by the medical officers of health . . . and working in harmony with the general practitioner. The first unit consists of the tuberculosis dispensary. . . . The second unit consists of the sanatoria, hospitals, &c., in which institutional treatment is given. . . . The committee are of opinion that the tuberculosis dispensary should be the common centre for the diagnosis and for the organisation of treatment of tuberculosis in each area, at which the various bodies and persons connected with the campaign against tuberculosis will be brought together. The aim should be that no single case of tuberculosis should remain uncared for in the community, and that whatever services the scheme provides should be available for all cases of the disease. Next to the tuberculosis dispensary should stand the second unit, consisting of a system of sanatoria, hospitals, farm colonies, open-air schools, &c. The tuberculosis dispensary should be linked up to these institutions, for which it will act as a clearing-house."

The dispensary acts as a receiving station and centre of diagnosis and a clearing station and centre of observation. It is also the place at or from which contacts are examined and the centre for after-care. The dispensaries fulfil a most useful function, and in some areas as many as 80 per cent. of the notified cases of tuberculosis are diagnosed at the dispensaries before the notification is sent in, as most suspected cases are sent there by their private or panel practitioners; other cases are discovered as a result of the examination of contacts by the tuberculosis officer.

The total number of beds in sanatoria and hospitals now provided by local authorities or paid for by them in voluntary sanatoria or hospitals is 26,373. At tuberculosis dispensaries 143,531 new cases were examined in 1932, including 48,531 contacts, and the total attendances were 782,602.

The authorities which administer the anti-tuberculosis scheme, as also the venereal diseases scheme, are the county councils and the county borough councils.

Mention may be made here of *bovine tuberculosis* which, it is estimated, causes 2000 human deaths a year. Tuberculosis is very prevalent amongst the cows of this country and some 10 per cent. of the churns of milk arriving in our great cities contain living tubercle bacilli, though much of it is heat-treated before sale to the public. When an urban medical officer of health has ascertained by the biological test that milk is tuberculous, he notifies the medical officer of health of the county of production. The latter then sends a veterinary inspector to examine the herd, and he has power to order the slaughter of any tuberculous animal he may discover. The farmer receives compensation for the loss of his cow.

The Tuberculosis Order requires a farmer to notify the local authority under the Contagious Diseases of Animals Acts when he suspects that one of his cows is tuberculous, and it is an offence for him to sell milk which he knows to be tuberculous.

The *venereal diseases scheme* was inaugurated in 1917 and followed the recommendations of the Royal Commission which had reported in the previous year. The war had brought into prominence the importance of taking every possible step to combat the ravages of these diseases and urgent action was essential. The essence of the scheme is the provision of clinics at which free treatment is given under confidential conditions to all who apply. At first the clinics were all at voluntary hospitals, but during recent years a number of ad-hoc clinics in separate buildings have been provided by certain local authorities and they have been very largely attended. The total number of clinics in England and Wales is now 177, and in 1932 50,824 new cases of venereal disease were treated, 31,125 cases of non-venereal disease came for examination, and the total attendances numbered 2,984,270.

Under this scheme in-patient treatment is provided where necessary and pathological examinations are made, free of charge, of specimens sent by private practitioners. Approved private practitioners—that is, those who have had special experience in intravenous medication—are also supplied free of charge with arsenobenzol preparations for use in the treatment of their private patients.

National Health Insurance Scheme

The preamble to the National Health Insurance Act of 1911 states it is "an Act to provide for insurance against loss of health and for the prevention and cure of sickness," &c.

There are many who think that its use as an instrument for the prevention of disease has not been great; but a system of capitation payment for medical attendance should, in theory at all events, have been the very greatest incentive to the practice of preventive medicine on a broad scale. There are 16,010,000 insured persons in England and Wales and some 16,780 practitioners engaged in health insurance work, and the day by day inculcation into their patients individually, wherever this is appropriate, of what they should do to prevent a return of the illness for which they have consulted their doctor should be of inestimable value in the promotion of public health. Certain panel practitioners have held meetings in halls hired by the Insurance Committee to which all their panel patients have been invited, and have addressed them on the subject of the prevention of ill-health. The local administration of the National Health Insurance Acts is in the hands of the Insurance Committees, which include in their membership representatives of approved societies, the insured persons, the doctors, and the county or county borough council as the case may be. Each county and county borough has its own insurance committee.

Control of Industrial Diseases

Beyond the inspection of workshops and workplaces by officers of the local sanitary authority, the "public agency" for dealing with the hygiene of factories and the control of industrial diseases is the Home Office, which acts through factory inspectors, factory surgeons, and a central medical staff. Factory surgeons examine juveniles on their entrance to factory life and reject them if they are unfit. It sometimes happens that dental or other treatment has been persistently refused while a boy is at school, but as soon as the parents learn that the factory surgeon will not pass him until the treatment is obtained, steps are at once taken to get it.

Cases of anthrax, lead, phosphorus, arsenical or mercurial poisoning and other industrial diseases coming to the notice of a practitioner must be notified to the chief inspector of factories at the Home Office.

General Hospital Provision

It is now an important part of the work of the county and county borough councils to administer the medical services of the former poor-law guardians. These include the management of hospitals and of sick beds in poor-law institutions and the control of the district medical service. Up to now their outlook has been largely confined to the curative side, but there is much scope for the exercise of preventive work which no doubt will be developed now that they are under the control of the large public health authorities.

In this connexion it must be remembered that the cure of a lesser ailment, which would otherwise develop into a major or even fatal one, is an important function of preventive medicine. The efficient treatment of fractures and other orthopædic conditions so that the patient can be returned to industry is essentially practical preventive medicine.

Mental Ill-health

Until comparatively recently mental hospitals were called "asylums" and their main function was the incarceration of those from whom the community needed protection. The cure and reinstatement in the community of those suffering from mental breakdown is attracting more and more attention. Recently the prevention of mental breakdown has occupied the attention of statesmen and others, and under the Mental Treatment Act, 1930, the counties and county boroughs are empowered to establish out-patient centres where patients suffering from mental illness may receive appropriate advice in the hope that a complete mental breakdown may be avoided. Provision is also made for in-patient treatment for a period without the need for certification as a lunatic. With regard to children, child guidance clinics are being established to give advice concerning maladjustment.

Prevention of Blindness

During recent years there has been a considerable reduction in the number of blind children. This is mainly due to the efforts which have been made by the maternity and child welfare authorities to prevent blindness resulting from ophthalmia neonatorum.

Under the Public Health Act, 1925, county and county borough councils are authorised to make such arrangements as they think desirable for assisting in the prevention of blindness, and some have established clinics for the purpose of advising persons who are blind or nearly blind as to what can be done to restore their sight.

Medical Research

The propelling force in advances in preventive, as in curative medicine, is research. The Local Government Board had a small sum available for research, but it was not until 1912 that a definite public agency charged with the duty of medical research was established. Its inauguration followed a provision in the National Health Insurance Act, 1911, to the effect that one penny per annum for every insured person was to be devoted to medical research. As a result of this the Medical Research Committee, now the Medical Research Council, came into being and the funds placed at its disposal by Parliament are now £139,000 a year.

Education of the Public

It will have been gathered from the above that public agencies for the prevention of disease have been generously provided. Some, like the improvement of environmental conditions, operate on all alike, though an appreciation by the public of their purpose would make them even more effective. For example, building by-laws require facilities to be provided for ventilation, yet the ignorant can render the by-law nugatory by stopping up the fireplace or the ventilator if they do not realise the importance of ventilation.

But many of the public agencies mentioned above cannot come into operation until the persons for whom they are provided apply for their assistance. For example, the tuberculosis dispensary organisation is useless if a tuberculous patient plies himself with patent cough medicines for months and only goes to his doctor or to the dispensary when the disease is already advanced. Again, the provision of hospital accommodation for measles is useless if the public regard measles as a trivial disease, wilfully expose their children to it so as to "get it over," and seek no medical advice until the patient is moribund.

Preventive medicine is only successful when it is in step with public opinion; but when public opinion is ready to accept a state or municipal service it should be there ready to hand. For these and other reasons representatives of the Society of Medical Officers of Health waited upon Mr. Neville Chamberlain, then Minister of Health, in 1924, and urged upon him the desirability of authorising health authorities to undertake educational work in their area by arranging for information to be supplied on questions relating to health or disease and for the delivery of lectures and the display of pictures in which such questions are dealt with. He acceded to this request and the necessary legislation for the provinces was included in the Public Health Act of 1925. Similar powers were given to London in the following year. This power, if properly used, should be of considerable value in promoting the public health. There is much knowledge with regard to healthy living which the public are anxious to learn. They read with avidity the advertisements of the vendors of patent medicines. It has been shown by the attendances at health exhibitions, health lectures, and at exhibitions of cinema films on health subjects that they are equally anxious to learn all that a local health authority is prepared to teach them, provided, of course, that it is put in an attractive way.

Conclusion

The above is a very brief outline of the work of public agencies for the prevention of disease. The tendency is for them to grow still further; but for even the present agencies to be fully effective the increasing coöperation of the public is essential. Progress in some directions, for example dental hygiene, is slow, but it is nevertheless sure. There is now a large cohort of persons, backed by all the power of the State, directly concerned in the prevention of disease. The results, though not uniformly successful, have been remarkable, and there is no doubt that as time goes on preventable illness and premature deaths will still further diminish.

W. ALLEN DALEY, M.D., M.R.C.P., D.P.H.
Principal Medical Officer, Public Health Department,
London County Council.[1]

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt. J. C. Gent is promoted to the rank of Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. T. C. Stevenson to *Effingham*.

Surg.-Lts. G. C. Martin and S. G. Suggit to *Rodney*; W. M. MacGregor and G. F. Jones to *Malaya*; G. H. C. R. Critien to *Excellent*, and J. O. Clyde to *Effingham*.

Proby. Surg. Sub-Lt. R. J. Carr to be Surg. Sub-Lt.

The following appts. are notified: Surg. Comdr. T. W. Drummond to *Malaya*; Surg. Lt.-Comdr. A. H. Shellswell to *Effingham*.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. A. S. Littlejohns retires on retd. pay.

Maj. R. W. Vint to be Lt.-Col.

The undermentioned Capts. to be Majs. (tempy. commns.): J. M. Pinkerton, J. B. Woodrow, J. D. C. Swan, and W. Parsons.

Lts. to be Capts.: J. R. Tobin, J. E. Moody, S. Griffin, D. K. Weston, and J. Davidson.

TERRITORIAL ARMY

Maj. W. W. MacNaught (Maj. Res. of Off.) resigns his commn. in the T.A.

Maj. W. McK. H. McCullagh to be Lt.-Col. and to comd. the 13th (4th Lond.) Gen. Hosp.

Maj. F. G. Widgery from 66th (S. Midland) Fd. Bde., R.A., to be Maj. with pay and allowances of a Capt.

E. A. Cormack, late Cadet Serjt., Edinburgh Univ. Contgt., Sen. Div., O.T.C., to be Lt.

INDIAN MEDICAL SERVICE

The prob. appts. of the undermentioned officers are confirmed: W. J. Moody, A. E. Kingston, B. A. Porritt, J. M. Sclater, J. D. Murdoch, C. F. Garfit, D. K. L. Lindsay, D. R. Tweedie, A. T. Andreasen, W. S. Morgan, M. S. Purvis, M. E. Kirwan, G. S. N. Hughes, J. W. Richmond, and A. D. Barber.

The undermentioned officers retire: Lt.-Col. (Bt. Col.) J. McPherson and Lt.-Col. V. N. Whitamore.

ROYAL AIR FORCE

Flight-Lt. E. A. Gudgeon is transferred to the Reserve, Class D.

RESERVE OF AIR FORCE OFFICERS

Flight-Lt. W. Heron relinquishes his commission on completion of service.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL

SUMMER SESSION, MAY 29TH–JUNE 2ND, 1934

The Pharmacopœia

Sir Henry Dale, introducing the report of the Pharmacopœia Committee, stated that 1407 copies of the British Pharmacopœia 1932, had been sold since November, bringing the total number of copies sold to date to 34,502. The Committee had received a second report from the Pharmacopœia Commission 1933–36, reporting that good progress had been made with the Addendum to the British Pharmacopœia 1932, which it was proposed to issue towards the end of 1936. This intermediate Addendum, said Sir Henry, was a new policy and would provide not only a convenient half-way stage between one Pharmacopœia and the next but also an opportunity to make such additions and adjustments as might be desirable in order to secure uniformity with the 11th United States Pharmacopœia which would be published in 1935. Active work was being carried on in the laboratory which the Council had provided, not only in preparation for the Addendum but also in dealing with the many helpful comments and criticisms which had been proferred on the 1932 issue. The Commission had given careful consideration to the newer remedies which were coming into general use, and monographs on a number of new chemical substances and preparations were under consideration by the Committee. It is obvious that every issue must contain as complete accounts as possible of vitamins and antitoxins, sera, and other animal products. Another problem before the Committee was the very large number of remedies which are virtually monopolies and which are continually taking their place in the practitioner's armamentarium. A recent meeting of the Committee had considered whether such substances ought or ought not to be included in the Pharmacopœia or in a companion volume, and a subcommittee had been appointed to discuss the matter. The adoption of the report was seconded by Dr. J. W. Bone and was carried unanimously.

Medical Education and Examination

The Examination Committee presented a report on the pre-registration examination and length of the curriculum, and on the English examination reports and visitations. The Education Committee also had two reports, one on the curriculum and the other on various matters referred to it. Prof. J. B. Leathes, introducing this report, pointed out the valuable data which were embodied in the tables showing the requirements of the licensing bodies in regard to the medical curriculum. These had been set forth in three groups: those licensing bodies requiring at least 5 years; those requiring more than 5 years; and the London schools. Three years for clinical study were now required by all the licensing bodies, and the scheme of a pre-registration examination in chemistry and physics had been followed by most of the bodies, particularly those who did not teach. The bodies which provided instruction, however, were less willing to relinquish the teaching of physics and chemistry to secondary schools and retained control of these subjects to some extent. The result had been an increase in the minimum duration of the curriculum, but at the same time the scientific foundations of medical education had become more secure, though possibly at some sacrifice to school training in Letters.

Another point on which the Council had laid much stress was the abolition of any separation between clinical and pre-clinical study. Courses in applied anatomy were now given in almost all schools, and courses in applied physiology also, though not so consistently. It was the experience of a number of teachers that students were far more eager to learn these subjects during their clinical years, when they were in a position to appreciate the value of them. Courses in radiology were given in most places in the final year, though some teaching bodies did not require special evidence of instruction, as the use of radiograms was so universal in medicine and surgery that examination in these subjects would reveal the ability of a student to interpret X ray findings.

"EVIDENCE OF GENERAL KNOWLEDGE"

The attention of the Committee had been drawn, said Prof. Leathes, to the fact that religious knowledge, though recognised by many university and licensing bodies as a subject of general education, was not so recognised by the Council. The Committee recommended that no action be taken in this matter.

Prof. Langdon Brown protested at this decision; he thought it was a great pity that it should go out from the Council that knowledge of Biblical history was not regarded as evidence of general knowledge. The University of Cambridge, he said, had drawn his attention to the matter and he asked on what grounds the Committee had come to this decision.

The Conjoint Examining Board, Prof. Leathes added, had addressed the Committee in November, 1933, drawing their attention to the variation in the scope and standard required in the London Matriculation, Oxford and Cambridge School Certificate, and College of Preceptors' Senior Certificate (Credit Standard) Examinations. The Examining Board thought it desirable that the whole of the preliminary examination should be passed on one occasion, and that it should consist of English, another language, any three of the following subjects, provided that one were taken from each section: (1) arithmetic, algebra, geometry; (2) zoology, chemistry, physics, and one of the following subjects: Latin, Greek, French, Spanish, Italian, history, and geography. They therefore thought it desirable that the present credit standard of the College of Preceptors be abolished and that an ordinary Senior Certificate of the College be accepted, provided that it was specially endorsed to show an aggregate of not less than 40 per cent. with a standard of not less than 30 per cent. in any subject. The Education Committee of the General Medical Council had agreed that these proposals would provide a preliminary examination that would be satisfactory evidence of general education.

Sir Henry Brackenbury dissented from this conclusion of the Committee. He would be willing to accept the words "A less unsatisfactory evidence," but he could not regard any preliminary examination in which mathematics was not essential as satisfactory evidence of fitness for medical study. He asked how it was possible for anyone to pursue scientific medical studies to the degree necessary for the public protection without, for instance, any knowledge of algebra.

Mr. Bishop Harman agreed, and pointed out that even the Examining Board had only used the expression, "More satisfactory evidence."

Dr. Letheby Tidy pointed out that a number of the licensing bodies did not require mathematics for amination for their matriculation, and named the niversities of Oxford, Cambridge. Manchester, iverpool. Sheffield. Birmingham, and Bristol. It uld not logically be said, he argued, that the eneral Medical Council considered mathematics ecessary if it accepted the examinations of these odies. Moreover, mathematics was often a matter very great difficulty to certain individuals, dividuals who did not necessarily make bad doctors.

Prof. J. S. B. Stopford said that there was a isunderstanding : the University might not demand athematics for its entrance, but there were faculty equirements over and above those of the University s a whole. In Manchester English, Latin, and athematics were always compulsory for the faculty f medicine.

Prof. E. Fawcett said that Bristol from the start ad demanded mathematics up to matriculation tandard for entry to the faculty of medicine though ot to the faculty of arts.

Mr. R. J. Johnstone suggested that the Report be mended to read "more satisfactory," and Prof. eathes accepted this suggestion, remarking; however, that the indirect attack on mathematics through physics might be just as good an education as the irect attack which some people found very difficult.

TUBERCULOSIS

The Education Committee had suggested in May, 1933, that they should inquire of the Licensing Bodies if they were satisfied that candidates had sufficient opportunity for studying the early stages of tuberculosis. All the licensing bodies had now replied that they were satisfied, with the exception of Birmingham and Cambridge.

Prof. Langdon Brown pointed out that at Cambridge candidates had not been taught that part of the subject within the bounds of the University, and the examiners had noticed a great variation among different candidates as to the knowledge of physical signs. They had correlated this with the varying opportunities given to the men to attend tuberculosis departments and institutions.

Sir George Newman remarked how satisfactory it was to get such a reply, as there had been widespread criticism throughout the country of the inability of medical schools to teach either maternity or tuberculosis. It was most gratifying to learn that there was in fact no difficulty, with the exception of Birmingham. He wondered what was the unique trouble of this university.

Prof. Gamgee said that the Report from Birmingham had given a wholly incorrect impression. There were plenty of cases in the out-patient department for the teaching of early tuberculosis and he would ask the University to send a supplementary report.

New Penal Cases—(*Concluded*)

ALLEGED FALSE REPRESENTATION OF FEES

The Case of Anczel Freitag, registered as of 27, Selhurst-road, South Norwood, S.E.25, L.M.S.S.A. Lond. 1929, who had been summoned to appear before the Council on the following charge :—

"That being a registered medical practitioner, you on Dec. 21st, 1932, in reply to an inquiry by the County Borough of Croydon Insurance Committee, did falsely represent to such committee that you had been paid the several sums by the several patients as set out : Edith Goldsmith, 3*s.* 6*d.*; Albert Moon, 3*s.* 6*d.*; Nellie Moon, 7*s.* 6*d.*; Jessie Plackett, 2*s.* 6*d.*; whereas in fact you had been paid the several sums by the several patients as set out : Edith Goldsmith, £1 11*s.* 6*d.* (being nine visits at 3*s.* 6*d.* each); Albert Moon, £17 6*s.* 6*d.*; Nellie Moon, 10*s.* 6*d.*; Jessie Plackett, 7*s.* 6*d.* Such representation was made by you improperly and fraudulently with the intent and for the purpose that the said committee when making the adjustment of payments due to you for your remuneration in respect of the treatment of insured persons under the National Health Insurance Acts should only deduct the several amounts set out by you in your letter of Dec. 21st, 1932. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The case was reported to the Council by the Minister of Health.

Mr. Hempson, solicitor to the Medical Defence Union, accompanied Dr. Freitag.

Mr. Hempson objected to the consideration of this matter by the Council at all, as the offence was a crime and a man accused of a criminal offence was entitled to be tried by jury under the rigid procedure of the courts. He suggested that the charge was an abuse of the Council's process by the Ministry of Health, which had its own appropriate remedy by inquiry.

Mr. Harper argued that the jurisdiction of the Council was to deal with the Register regardless of what happened outside.

The Council deliberated on the submission in camera and over-ruled it. Mr. Harper then addressed the Council.

Mr. Albert Moon, who is blind and partially paralysed, gave evidence; Mr. Harper read his statutory declaration and Mr. Hempson cross-examined him as to his attendances. He had paid respondent at each attendance; he had never had a receipt, nor had respondent made any record. He denied that the dispenser had told him the apparatus was out of order in December, 1932. His recollections were very hazy, he said. He had received a cheque for £17 odd from the Insurance Committee in repayment of fees.

Mrs. Moon gave confirmatory evidence.

Mr. Hempson objected to the admission of statutory declarations from persons not called as witnesses, and was over-ruled. Mr. Harper read a declaration from Edith Goldsmith, but was not allowed to put in evidence the finding of the Insurance Committee. The Minister, he said, had ordered respondent to refund sums to patients and had fined him £15.

Dr. Freitag gave evidence on his own behalf, agreeing that Moon and Goldsmith had been panel patients to whom he had given electrical treatment. He had sent in forms G.P. 45 in respect of them in 1931, showing that he was charging them fees for specialist services as set forth in the regulations. In 1929 he had made a similar claim, and simple sunlight treatment had been regarded by the committee as of specialist character. Not till 13 months after the forms had been sent in had he received the decision of the committee. He had given diathermy and faradism; and he produced his appointment books to show that only 47 treatments had been given. The battery of the faradic apparatus had run out in December, 1932, and had never been renewed, as the patient was not benefiting. Moon had paid 3*s.* 6*d.* on the first occasion, but no more. He produced his cash book in which he recorded all fees paid. He had been satisfied that the treatment was outside the panel service, on account of the 1929 decision. Mrs. Goldsmith had had diathermy and sinusoidal current and had paid 3*s.* 6*d.* the first time only; subsequently the dispenser had given the treatment. The visits were recorded in the appointment book. At the Insurance subcommittee there was no legal guidance as to rules of evidence and procedure, and accused was not represented by a lawyer. No inquiry at all had been held by the Ministry.

Mr. Harper read the finding of the Insurance Subcommittee to respondent, who recognised it. In reply to the Legal Assessor, he said he had produced his books to the subcommittee; he kept them himself, except for an occasional audit. He had not charged either patient after the first treatment because he had not given personal supervision.

Dr. E. W. Bone asked what the responsible body, the Croydon Insurance Committee, had done on receiving the report of its subcommittee, as this had not been stated. Dr. Freitag replied that they had accepted the report, and Mr. Hempson read the recommendation that respondent be severely censured and that the Ministry should be advised to withhold an appreciable sum from his remuneration. In reply to Sir Robert Bolam, Dr. Freitag said he knew he had a right to appeal but had not appealed because he had been working for his D.M.R.E. and had no time to spare.

Miss E. Pettitt, Dr. Freitag's dispenser, confirmed Dr. Freitag's account of the failure of the apparatus early in December and of the administration by her of treatment to Mrs. Goldsmith, who had never paid witness anything at all and had not seen the doctor privately so as to have an opportunity to pay a fee without witness's knowledge. In reply to Mr. Harper she said she had not given evidence before the subcommittee.

Mr. Hempson addressed the Council, repeating that this inquiry, if not an abuse of the Council's procedure, was at least a matter requiring careful consideration in the interests of the whole profession. Mr. Harper also addressed the Council, which did not find the facts proved to its satisfaction and therefore dismissed the case.

POLICE-COURT AND ASSIZE-COURT CONVICTIONS

The Case of William Graham, registered as of Bridge House, Manor-road, Tynemouth, M.B., B.S. 1923, U.Durh., who had been summoned to appear before the Council on the following charge :—

> "That you were at the Newcastle Assizes commencing on Oct. 30th, 1933, convicted of unlawfully killing one William Wood Walton and were fined £100 and ordered to pay the costs of the prosecution."

There was no complainant in this case.

Mr. Graham appeared, accompanied by Mr. Hempson, solicitor.

Mr. Harper, solicitor to the Council, explained that respondent had lost proper control of his motor-car due to sleepiness, and had overtaken a couple of pedestrians on the wrong side of the road and killed one of them. He had shortly before the accident discovered that he was driving on the wrong side of the road at 40 m.p.h., but had continued at that speed, thinking he had shaken off his sleep. No suggestion was made that drink was involved. Mr. Justice Humphreys, in passing sentence, had expressed the view that accused had been punished enough, and should be capable of continuing to live as a good citizen and doctor; he had not seen fit to disqualify the accused from continuing to drive. Mr. Hempson urged that nothing in Mr. Graham's conduct redounded in any way to his discredit as a medical man and a gentleman. He had been exhausted by hard work in his practice and by a number of night calls.

The Council decided not to direct the Registrar to erase Mr. Graham's name.

The Case of James Paton Neilson, registered as of 90, Liverpool-road, Southport, M.B., Ch.B. 1922, U.Glasg., who had been summoned to appear before the Council on the following charge :—

> "That you were convicted of the following misdemeanours, viz.: (1) On Dec. 9th, 1929, at Southport County Borough Police-court, of being drunk in charge of a motor-car, and were fined £15 and your licence suspended for 12 months; (2) on Nov. 21st, 1933, at the Lincoln City Police-court, of driving a motor-car whilst under the influence of drink to such an extent as to be incapable of having proper control, and were fined £50 and £3 13*s.* witness allowances, and disqualified for holding or obtaining a licence for five years."

There was no complainant in this case.

Mr. Carthew appeared on behalf of the respondent, instructed by Messrs. Le Brasseur and Oakley, solicitors to the London and Counties Medical Protection Society. Explaining that Dr. Neilson was in Canada, he read a letter from the respondent stating that he had obtained permission to practise in Canada, had started a new life in a lonely and pioneer district, and had already visited many families scattered over a vast area; he expressed deep regret for his "foolish self-indulgence" and requested the Council to accept his assurance of perpetual abstention and good behaviour in future. Mrs. Nora Neilson, respondent's wife, a medical practitioner, testified that at the time of the Lincolnshire incident respondent had been extremely anxious at the non-success of a new practice, and stated that she intended to join her husband with their children when he had established himself. Mr. Carthew read some statutory declarations testifying to the good character of the respondent. The Council decided not to erase Dr. Neilson's name.

The Case of George Francis Donaldson Perrott, registered as of 25, Bromefield, Stanmore, Middlesex, M.R.C.S. Eng. 1928, L.R.C.P. Lond. 1928, who had been summoned to appear before the Council on the following charge :—

> "That you were convicted of the following misdemeanours, viz.: (1) On April 13th, 1933, at the Staple Hill, Bristol, Police-court, of being in charge of a motor-car when under the influence of drink to such an extent as to be incapable of having proper control, and were fined £50 and £2 6*s.* costs and your licence suspended for five years; (2) on Nov. 17th, 1933, at the Marylebone Police-court, of being drunk and disorderly, and were fined 10*s.* 6*d.* or seven days' imprisonment."

There was no complainant in this case.

Dr. Perrott was accompanied by Mr. T. Carthew, counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors, on behalf of the London and Counties Medical Protection Society.

Mr. Harper laid the facts before the Council and Mr. Carthew addressed it. After consideration in camera the President pointed out that the respondent had been twice previously before the Council on similar charges. On the first occasion he had promised to abstain from alcohol and had produced satisfactory testimonials at the end of a year's probation. The President continued :—

> "Being a medical council, perhaps we are more familiar than an ordinary jury with the difficulties of your case, and we have decided to take a course which we believe to be very much in your interest. We will put you on two years of probation. At the end of one year, we shall expect to have reports on your conduct from persons such as those from whom you have previously submitted testimonials. . . If there should be any further lapse on your part during that time, you will be again summoned to appear before the Council."

Penal Cases Postponed from a Previous Session

The Case of Peter John Gormley (formerly Grimes), registered as of 167, Wigan-road, Ashton-in-Makerfield, Lancs, M.B., B.Ch. 1919, N.U. Irel., who had appeared before the Council at its summer session, 1933, on the charge of having been convicted on two occasions of driving a motor-car whilst under the influence of drink, and of other motoring offences. The Council at that session had postponed judgment for a year subject to the usual proviso that the respondent should within that time give the names of a number of his professional brethren from whom the Council could request a report on his character and conduct in the interval. Mr. Gormley now appeared, and Mr. Harper read a number of letters which showed that his behaviour had been satisfactory in every respect. The Council did not see fit to direct the erasure of his name.

The Case of Victor Cecil Tughan, registered as of 4, Stanton-court, Greenhill, Weymouth, M.R.C.S. Eng. 1925, L.R.C.P. Lond. 1925, who appeared before the Council charged with having been convicted on two occasions of driving a motor-car whilst under the influence of drink. Mr. Tughan should have appeared at the last winter session, but the hearing was adjourned because of his illness. After hearing the Council's solicitor and Mr. Tughan, the Council postponed judgment for six months subject to the usual provisos.

Penal Cases Reported by the Dental Board

In accordance with custom, the Council heard penal cases in public and deliberated on its findings in camera.

The Case of John Holden Beckett, registered as of 10, St. Peter's-road, Leicester, L.D.S. R.C.S. Eng. Mr. Beckett was not present, nor was he represented. He had been twice convicted of travelling on the railway without having paid the fare and with intent to avoid payment thereof. The Dental Board had found the charges proved and had required testimonials, all of which had proved unfavourable or inadequate. The Board had therefore found that his name ought to be erased from the Register. Mr. Harper, the solicitor to the Dental Board, gave the Council some details of the case, and after deliberation in camera the President announced that the Registrar had been directed to erase Mr. Beckett's name from the Dental Register.

The Case of Nathan Moss, registered as of 29, Shoot-up-hill, Cricklewood, London, N.W.2, dentist 1921, who had been found guilty by the Dental Board of advertising for the purpose of promoting his own professional advantage by the issue of circulars, 10,000 of which had been printed and circulated by an addressing firm. He had been warned by the Registrar previously. Mr. Moss appeared, accompanied by Mr. Scott Henderson, counsel, instructed by Messrs. Bulcraig and Davis, solicitors. The Registrar read the report of the Dental Board. Mr. Henderson addressed the Council on Mr. Moss's behalf. He expressed his client's regret, and criticised certain proceedings before the Dental Board and the wording of the charge. He adduced evidence that certain persons there mentioned had been in fact patients of Mr. Moss; and declared that the Dental Board had appeared to accept this evidence. He argued that non-attendance for two or three years could not make a patient a patient no longer.

Mr. Harper addressed the Council and admitted that the circular alleged to have been addressed to Mr. Alfred Smith, one of the persons whose evidence had been heard by the Dental Board, was addressed to "Mr. S. Smith" and might reasonably be supposed to have been intended for Mrs. Sophia Smith, the wife, who was in fact a patient of the practice.

The President, after deliberation in camera, announced that the Council did not see fit to direct the Registrar to erase Mr. Moss's name.

The Case of Lawrence Louis Symmonds, registered as of 58, High-street, Bargoed, Glam., L.D.S. R.C.S. Eng., who had been summoned before the Dental Board on a charge of setting up a dental clinic, with reduced fees, where only himself and his assistants were allowed to treat patients. The conditions of attendance were set forth in a circular which he had handed and sent to various medical practitioners in the attempt to obtain patients. The Dental Board had found him guilty of advertising to attract practice and had recommended the erasure of his name.

Mr. Symmonds appeared in answer to his notice, accompanied by Mr. T. Carthew, counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors, acting on behalf of the London and Counties Medical Protection Society. The Registrar read the notice and Mr. Carthew addressed the Council, saying that Mr. Symmonds had been a "Dentist 1921" before qualifying L.D.S., and had for years had the largest practice in the district. With one exception, he and his assistants had been the only dental surgeons in the neighbourhood; nor were there any other dental clinics. The area was a very poor one, and people could not afford to travel to Cardiff or Newport. Mr. Symmonds had taken responsible advice before opening his clinic, and had written to all the doctors in the neighbourhood asking for an interview, in order to obtain their views. They had all said that some such scheme was badly wanted.

There was no suggestion that the respondent had approached any but doctors; and he had offered to explain the scheme to the Rhondda Valley Medical Association. The scale of fees was not one which offered any profit, and he had refused to do the work for any patient who had not a certificate of poverty from a doctor.

Mr. Harper addressed the Council, and said that other dentists in the district ought, in the opinion of the Dental Board, to have been brought in; even if "only Dentists 1921" they were all dentists. He read certain question and answers from the report of the inquiry before the Board. He argued that the scheme had not been a charitable one, but an attempt to increase respondent's own practice.

The Council decided not to erase the respondent's name from the Register.

LISTER INSTITUTE OF PREVENTIVE MEDICINE

THE 40th annual report of the governing body records the research work in progress in the various departments. We select below from the mass of interesting material notes on a few of the investigations being carried out in the department of bacteriology, serology, and experimental pathology.

Studies on Viruses

Vaccinia.—Continuing his studies on the cultivation of vaccinia virus on cell-free fluid media, Dr. G. H. Eagles has completed a series of passages in which the washed elementary bodies obtained from deposits of

Berkefeld V. filtrates of dermal virus centrifugalised at high speed were used for the initial seeding. "Kidney extract," prepared by grinding, salting, and high-speed centrifugalisation, constituted the culture medium. Seven generations of subculture have been carried through without apparent loss of potency, the final subculture representing a multiplication of 20^7 times the original potency of the seeding as judged by animal titrations.

As in previous series, considerable irregularity was experienced among individual flasks set up at the same time. The few workers in other countries who have attempted the cultivation of vaccinia in cell-free media have not succeeded in securing definite evidence of growth, and in the attempt to reconcile such conflicting results, Dr. Eagles is now, in conjunction with Dr. A. B. Sabin (Fellow, National Research Council, U.S.A.), undertaking a fresh series of experiments and certain possible sources of error are being investigated.

The use of *elementary body suspensions for vaccination against small-pox* is being investigated. These suspensions, derived from filtrates of dermal virus by high-speed centrifugalisation, possess high activity and can be prepared with ease and economy. As they represent the virus in the purest form and are bacteriologically sterile, an investigation is being made of their activity under various conditions of storage.

Dr. C. R. Amies has found that such suspensions, in a medium of simple broth, retain their activity for considerable periods when kept at room temperature and, indeed, for several weeks, at 37°, the survival periods comparing very favourably with those obtained with crude pulp in saline or glycerol saline. At 0° C. the loss of activity is, as might be expected, small.

Dr. Amies has not been able to confirm the claim recently made by Russian workers that vaccinia virus can be readily cultivated in vitro in symbiosis with yeasts.

Dr. M. H. Finkelstein, using a modification of the complement-fixation technique introduced by Mackie and Finkelstein in 1928, has shown that no fixation takes place with hyperimmune sera and material from vaccinia if the elementary bodies are absent.

Varicella and herpes zoster.—Dr. Amies, following up his previous work on varicella, has fully confirmed the finding of elementary bodies in herpes zoster and has obtained pure suspensions of them by high-speed centrifugalisation of the vesicle fluid. Agglutination tests lend further support to the belief that the two viruses are closely related, if not identical. The relationship of fowl-pox to pigeon-pox is being studied by Dr. Finkelstein and the properties of louping-ill virus grown in vitro by Mr. D. W. Henderson.

A virus recovered by Dr. Sabin from a human case of acute ascending myelitis, associated with focal necroses in viscera ("B" virus), has been found to be readily communicable to rabbits, in which an ascending paralysis leading to fatal issue regularly followed an intradermal injection after an interval of some days. These animals, like the original human case, presented necrotic foci in certain viscera similar to those associated with highly virulent vaccinia and herpes infections. The further investigation of this virus from the point of view of possible relationship to the herpetic group of viruses is being actively pursued by Dr. Sabin.

Spore-bearing anaerobes.—Work commenced last year on the antibacterial mechanisms associated with *C. tetani* prophylaxis has been continued.

Experiments on the efficacy of high titre antitoxic sera in protection against *C. tetani* spore infection have shown that such sera only delay the onset of the disease, which later ends fatally. A successful issue may, however, be obtained by repeated intravenous inoculation of antitoxin until the local lesion produced by the activator is no longer effective in maintaining conditions suitable for the reproduction of the organism and the associated toxin production. The survival of spores in such recovered animals is being investigated.

Studies on virulence.—Dr. A. Felix, in collaboration with Miss R. M. Pitt, has studied the relationship between virulence and susceptibility to the action of the "O" antibody working with *B. typhosus*. In experiments with mice it has now been found that highly agglutinable strains of *B. typhosus* are of low virulence, while inagglutinable strains are highly virulent. Both types of strain were carefully tested by all the known methods for detecting "roughness," and were found to be perfectly smooth. There was also no difference in their content of "H" antigen.

The inagglutinability of these strains is strictly a property of the living organisms. The nature of the factor underlying the phenomenon is as yet entirely obscure. The results do not contradict the view that rough forms are non-virulent, but they do indicate that the mere presence of smooth "O" antigen does not completely define virulence. Some obscure property is required to render this antigen resistant to "O" antibody.

RESISTANCE TO INFECTION AND GENETIC CONSTITUTION

Through the kindness of Dr. L. T. Webster, of the Rockefeller Institute, and Prof. J. B. S. Haldane, of University College, selected and pure line races of mice have been obtained, and the breeding of them has been successful enough to permit of the testing of groups of these races for resistance to a variety of infective agents, including *S. typhi murium*, *S. enteritidis*, *M. pneumoniæ*, and the virus of louping-ill. Dr. H. L. Schütze and Dr. Finkelstein, who are conducting these experiments, have already been able to demonstrate very striking differences in the susceptibility of these strains of mice to the test infections selected, and it is hoped in this way to acquire some insight into various processes of immunity.

In the division of protozoology during the year Miss Muriel Robertson, D.Sc., has been concerned with the study of various aspects of the effect of gamma ray irradiation on the growth of *Bodo caudatus*.

(*To be concluded*)

MEDICINE AND THE LAW

Jurisdiction of the G.M.C.

OUR learned contemporary, the *Law Journal*, voices misgivings which have also been expressed elsewhere over the jurisdiction lately asserted by the General Medical Council in a case referred to it by the Minister of Health, and reported on page 1307 of our present issue. In effect, a panel practitioner was accused of a fraud amounting to a misdemeanour, and there was a question which was the proper tribunal, the G.M.C. or a court of law. The local medical service subcommittee had found that the practitioner had offended against the medical benefit regulations. The complaint against him was that he had understated to the Croydon Insurance Committee the fees paid to him by certain panel patients for special treatment. The suggestion was that he planned this alleged irregularity in order that the committee, when adjusting his remuneration, might make smaller deductions than would otherwise have been made. The Minister of Health fined him £15 on the report of the investigation and, without ordering a disciplinary inquiry under the National Health Insurance Act, sent the case to the General Medical Council. When the Council began the hearing on June 2nd, its jurisdiction was challenged on a preliminary objection on behalf of the respondent doctor. It was urged that he had a right to have this criminal charge of misdemeanour tried in a proper court of law before a jury and upon sworn evidence. The Council overruled the objection, examined the facts, and dismissed the case.

The Council has, of course, a statutory jurisdiction (under Section 29 of the Medical Act) to make due inquiry into an allegation of "infamous conduct in any professional respect," and no one will deny that an allegation of the fraudulent manipulation of accounts as to fees might come within these words in the section. But the authorities who administer the criminal law might well object to the Council assuming an original jurisdiction in every case of alleged felony and misdemeanour where the accused is a doctor. The very idea seems to recall the claim of the mediaeval Church to exercise temporal jurisdiction over its members—a claim which allowed "benefit of clergy" to furnish a simple form of clemency to first offenders. One inevitable question arises: if the Council exercises jurisdiction over the doctor in a charge of fraud, what is the effect on subsequent proceedings in a police-court or at assizes? There is an established rule of the common law that a man may not be twice put in peril for the same offence. The Council may not be within the letter of the rule as a competent tribunal whose acquittal bars any fresh indictment in the same matter. But if, in the recent case dismissed by the Council on June 2nd, fresh criminal proceedings were now instituted elsewhere, there would be a feeling that the spirit of the rule had somehow been broken.

VOLUNTARY HOSPITALS CONFERENCE

A CONFERENCE of voluntary hospitals, convened by the British Hospitals Association and the Incorporated Association of Hospital Officers, was opened on June 13th by H.R.H. The Prince of Wales. The Prince was received by the Lord Mayor, Sir Charles Collett, and Sir Arthur Stanley (President, British Hospitals' Association). After the appropriate presentations had been made, the Prince declared the conference open and a vote of thanks was proposed to him by the Lord Mayor and seconded by the Hon. Arthur Stanley. Owing to the sudden illness of Sir Ernest Morris, a paper by him on "Voluntary Hospitals, Past, Present, and Future," could not be read and the session devoted to the subject was abandoned.

At the session which immediately followed the opening ceremony the chair was taken by Lord Macmillan, chairman of the Hospital for Sick Children, Great Ormond-street, for a discussion on

The Out-patient Department

Lord MACMILLAN said that the out-patients' department presented difficult and important problems. It had two aspects: that of policy and that of method. Under policy came the great question whether the out-patients' department performed the functions it was designed to serve; whether it was attended by the right type of patient, both from the social and medical aspect; whether enough scrutiny was made of those attending; and whether the best possible use was made of the many organisations which had come into being since the hospitals were instituted. That blessed word "coördination" really did stand for something of moment. As to method, the mere mechanical handling of out-patients was difficult. Often the authorities were hampered by accommodation that had been completely outgrown; that was a problem for the architect. Then there was the question how to get patients there at the right time. He himself had an appointment with his dentist at 4 o'clock, but he was quite prepared to study antideluvian journals for some time before being admitted. If the private consultant could not keep precise appointments, what of those handling immense crowds? Waiting was no fault of the staff; none could tell how long a given case would take and no purely mechanical arrangement could be arrived at.

The Earl of ONSLOW, chairman of the Out-patient Committee of King Edward's Hospital Fund for London, opened the discussion. He said that one of the great difficulties of out-patient treatment was that of getting a true picture of the situation. There was really only one substantial complaint: overcrowding. One of its chief causes was the popularity of the hospital. Numbers of patients might just as well go elsewhere and could get the same treatment, often from the same specialists, in clinics provided by the local authorities. A certain amount of waiting was probably unavoidable, but something could be done by time-saving methods and by reducing the number of patients. No hard-and-fast rule could be laid down for every institution, but hospitals could now pool their experience, and the King's Fund had appointed a committee to this end. Undoubtedly old-fashioned and inadequate accommodation had accounted for much difficulty, and much structural alteration could be done at small cost. It was important that out-patient time-tables should be widely and accurately known, so that patients should not arrive far too early in error. Difficulties in the way of introducing an appointment system were the unpunctuality of patients, the necessity of securing a constant stream so that the consultant's time was not wasted, and the complication of unexpectedly short or long cases and the arrival of urgent cases. Moreover, a consultant who had all his patients for the afternoon before him could sift them, so that his assistants saw some while he got on with those reserved to himself and could leave as soon as he had finished. A partial appointment system, however, seemed possible; patients might be summoned in groups or classes at different hours, and appointments might be possible in special departments. Specialists should not have to do their own clerical work. As a counsel of perfection, there seemed much to be said for the British Medical Association's ideal of making the out-patient department purely consultative, but this seemed impracticable. The users of the hospital would object; they would not like asking their doctors for letters thus revealing suspicions of his treatment, and moreover many persons had no regular doctor.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE HOSPITALS SWEEPSTAKES AND MEDICAL RESEARCH

THE sweepstake on the Derby, which was drawn last week, brought a sum of £519,089 to the Hospitals Fund. The total amount which has been distributed, or is awaiting distribution, to the hospitals, as the result of the twelve sweepstakes which have been conducted, is £6,897,132. Some months ago the various hospitals which are associated in conducting the sweepstakes, agreed that they would be willing to allot a sum from the proceeds for the endowment of medical research, a method of allotment permitted by the Act of last year. A scheme has now been prepared by a representative expert committee and has been approved by the hospitals committee. The next step is to put it before the Hospitals Commission which advises the Minister as to the distribution of the Hospitals Fund. The details of the scheme are not likely to be made public until the scheme receives the approval of the Hospitals Commission, but it was stated last week that a substantial sum of money will be asked for and that the scheme will include provision for research to be carried out abroad, as well as at home, and by foreigners as well as by citizens of Ireland.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The annual elections at the Royal College of Surgeons in Ireland were held on June 4th. Mr. Seton Pringle has been elected president unopposed, and Mr. Adams A. McConnell, vice-president, also unopposed. Mr. Pringle has been vice-president since 1932. He is visiting surgeon to the Royal City of Dublin Hospital and surgeon to Drumcondra Hospital; he is also honorary lecturer on the pathology of bone in the School of Physic, Trinity College. Mr. Adams McConnell is senior surgeon to the Richmond Hospital, Dublin. He has been a Fellow of the College since 1911.

HEALTH COMMITTEE OF THE LEAGUE OF NATIONS

It is announced that Dr. Denis J. Coffey has been appointed a member of the Health Committee of the League of Nations. Dr. Coffey, who is the first Irish medical man to be appointed to this committee, is president of University College, Dublin, and also president of the Irish Free State Medical Registration Council.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

WATER SHORTAGE IN SCOTLAND

EARLY in the year the Department of Health suggested that the local authorities and other water undertakers should make a survey of their position and prepare plans for effecting economies in consumption and adding to their supplies. On June 4th they issued a second circular enclosing a summary of the Water Supplies (Exceptional Shortage Orders) Act. 1934. It is not in the cities that the greatest trouble will have to be faced. In the counties, when there is little snow in the winter, the wells tend to give out and typhoid fever used to appear regularly. Now typhoid is under better control, but other indirect results may have to be faced. Many of the small burghs are not very well supplied. The tendency in Scotland is to seek out gravitation supplies, and the departmental committee now sitting on the medical services some time ago issued an interim report recommending a survey of the water-supplies. This had been also recommended by the Royal Commission on Housing in 1917; but nothing has been done. The matter is urgent now and the department will have less trouble in rousing the activities of the local authorities. Previous experience would lead one to doubt whether advice to householders is likely to have much effect, but a stringent supervision of meters for "works" and particularly of street fire hose connexions ought to result in perceptible economy.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN

A total of 46,878 children received treatment last year at this hospital. During 1933 3013 cases were treated in the hospital. The average daily number of patients in the hospital during 1933 was 126, and the average duration 14·7 days. The ordinary income (not including legacies or special donations) amounted to £14,308, and the ordinary expenditure to £19,351. The number of in-patients is slightly less for 1933 than for 1932; but there has been a material increase of attendances at practically every branch of the out-patient department. Since the institution of child welfare clinics, which deal admirably with the minor diseases of children in their early stages, the hospital is now concerned almost entirely with acute medical and surgical cases involving greater care and attention from the nursing staff which has had to be increased. The extension of the off-duty hours allowed to nurses and probationers has also necessitated additions to the nursing staff.

ACUTE RHEUMATISM AND SCARLET FEVER

The report of this hospital also gives some interesting figures bearing on the relation between acute rheumatism and scarlet fever. During 1933 there was a very high incidence of acute rheumatic infection; 62 children who had not previously suffered from acute rheumatism, so far as could be ascertained, were admitted to hospital during the year, and a number of old cases readmitted. Now in 1933 there occurred in Edinburgh one of the largest epidemics of scarlet fever which the city has experienced, and it is significant that, coincident with this epidemic, there should have been a marked rise in the incidence of acute rheumatic infection. There is room here for a good deal of research, in view of the evidence that all these diseases are of streptococcal origin.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 2ND, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 2 (last week 2); scarlet fever, 2314; diphtheria, 1021; enteric fever, 21; acute pneumonia (primary or influenzal), 998; puerperal fever, 39; puerperal pyrexia, 109; cerebrospinal fever, 13; acute poliomyelitis, 8; acute polio-encephalitis, 4; encephalitis lethargica, 7; dysentery, 11: ophthalmia neonatorum, 98. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 11th–12th was as follows: Small-pox, 3 under treatment, 0 under observation (last week 5 and 0 respectively); scarlet fever, 1585; diphtheria, 1705; measles, 1890 (last week 2160); whooping-cough, 283; puerperal fever, 30 mothers (plus 6 babies); encephalitis lethargica, 269; poliomyelitis, 2; "other diseases," 153. At St. Margaret's Hospital there were 18 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 43 (11) from measles, 11 (3) from scarlet fever, 35 (7) from whooping-cough, 28 (5) from diphtheria, 40 (11) from diarrhœa and enteritis under two years, and 48 (9) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 4 fatal cases of measles; Barnsley, Gateshead, Newcastle-on-Tyne, Grimsby each 3: no other great town more than 2. Liverpool reported 6 deaths from whooping-cough, Birmingham 5.

The number of stillbirths notified during the week was 278 (corresponding to a rate of 37 per thousand total births), including 44 in London.

PUBLIC HEALTH

The L.C.C. Consultant Service

THE scheme to provide a consultant and specialist service in hospitals under the jurisdiction of the London County Council came into partial operation in July of last year and into full operation in October. The list of consultants and specialists participating in this scheme has since been published with the number of weekly sessions allocated to each ; during the last few months 197 of the 223 weekly sessions authorised have actually been held. Last Tuesday the Council reviewed the existing arrangements and decided that they do not call for radical amendment at present but should be continued at all events up to the end of the present calendar year. It is noteworthy that, although in March, 1933, scales of salaries were approved for full-time consulting physicians and surgeons, no appointment has been made of either, although two medical superintendents act as part-time specialists, as and when required, with additional remuneration. The appointment however of a full-time consulting radiologist is now being considered. The weekly sessions are shortly to be still further increased ; the authorised total of 223 sessions will apply to the group service as a whole without limitation of any particular type of consultant. Some minor readjustments are to be made. Extra remuneration is to be given for emergency visits when a consultant's total visits exceed the number for which he has been engaged ; the fee suggested is £2 12*s*. 6*d*. a visit. The same arrangement applies to part-time otologists and to thoracic surgeons, in the latter case the fee being £3 3*s*. a visit. In view of the fact that whole-time radiologists are not generally employed on Sundays, it is proposed to form a rota of consulting radiologists willing to undertake Sunday duty. The employment of refractionists to relieve the consulting ophthalmologists is contemplated when the alternative would be the employment of a new consultant for a weekly session ; the refractionist costs £95 a year for one session a week against the ophthalmologist's £125. Special anæsthetists have been called in as required at a fee of £2 2*s*. a session and this fee is now to replace the existing fee of 34*s*. for general anæsthetic purposes, which is regarded as too low. Thoracic surgeons are paid double fees for visits and consultant anæsthetists attending them are to have the same concession. At the Edmonton and Brentwood colonies need has arisen for regular supervision by a consulting neurologist, who will pay fortnightly visits to each colony at a salary of £125 a year. At the Lambeth Hospital Sir Comyns Berkeley on ceasing to be director of the X ray and radium units becomes hon. gynæcological surgeon, with an assistant employed for three sessions a week at £275 a year. For the children's hospitals at Carshalton and the Downs visits of a consulting general surgeon and consulting physician at monthly intervals are to be remunerated at £2 12*s*. 6*d*. a session. Finally the arrangement whereby the tuberculosis officers of the metropolitan boroughs are deemed to be hon. consultants for tuberculosis in the general hospitals is to be continued.

Recommendations under the Mental Treatment Act

The Board of Control has issued a list, revised up to May, 1934, of medical practitioners in England and Wales approved by the Board for the purpose of making recommendations under Section 1 (3) and 5 (3) of the Mental Treatment Act, 1930. An alphabetical list contains the names, qualifications, and addresses of about 2800 practitioners, and is followed by a local list of the cities and towns where they can be found. The new list, which takes the place of a previous list issued in October, 1932, can be obtained on application from H.M. Stationery Office or the Secretary of the Board of Control, Caxton House West, Tothill-street, London, S.W.1.

PANEL AND CONTRACT PRACTICE

Benefits for Married Women

IT is now more than a year since the sickness benefit for married women was reduced from 12*s*. to 10*s*. a week, and disablement benefit from 7*s*. 6*d*. to 5*s*. a week, and it would be instructive to compare the 1933 figures with those of 1932. In one society to whose figures the *National Insurance Gazette* has had access, claims from married women have fallen off, expenditure on them having been reduced by 34 per cent. It does not pay so many married women, the *Gazette* remarks, to claim benefit at the lower rate. Our readers will recall that before these reductions took place married women's claims were more than 100 per cent. above those expected when the actuarial calculation was made ; the reduction stated in the case of the society quoted will hardly make the financial position sound. Combined expenditure on sickness and disablement benefits of this society averaged 12*s*. per head for men, 14*s*. per head for spinsters and widows, and 22*s*. 6*d*. for married women. Since both classes of women pay the same contributions in stamps—the married women often pay for a shorter period when contributions cease after marriage —it does not seem fair division between the two classes. The married women's claims are in fact about 61 per cent. higher than those of other women. Insurance is often obtained by women after marriage for employment that is almost nominal ; they can claim insurance if they work only one day or even one hour a week. The healthy may not bother to do so, whereas those likely to be unfit insist on it with their employers. In these cases the women's earnings can only be little if at all higher than sick pay when on the funds ; they then have more time for their house duties which they are often able to do. This means that there is little inducement for the woman to declare off if she can persuade the doctor to give her a certificate. If the woman's husband is ill or unemployed she becomes the breadwinner, and as such is a genuine worker under the Act, but those who only work a few hours a week should not be considered as employed persons for the purpose of the Act. There is already a provision to exclude from insurance certain classes of work (e.g., cinematograph employees) involving less than a stipulated number of hours per week. The genuine worker, married or single, is penalised by unfair demands upon the funds. This is shown by the number of women's societies which have no funds left with which to pay ophthalmic, dental, or other additional benefit. The *Gazette* finds it definitely unjust that a minority of exorbitantly high claims by married women should deprive other insured women of benefits they might reasonably expect to enjoy.

Medical men might bear these considerations in mind when attending the casual-worker housewife for rheumatism or backache. They have a duty to their other insured patients as well as to the one who is receiving attendance and claiming benefit at the moment.

On Buying a Practice

Newly qualified practitioners often find difficulty in raising money with which to buy a partnership or a practice. To do this they are too apt to have recourse to firms who will advance the money without investigating whether the practice is good or not from the purchaser's point of view. The young practitioner may then find himself in possession of a practice in which the income does not enable him to pay off his liabilities to the lender as well as to provide him with a livelihood. We have already pointed out where this may lead.[1] The practitioner is forced to break his agreement with the moneylender, who is then in a position to intimate to the insurance committee his resignation from the panel and to nominate some other doctor to take over his patients. The situation for him is then disastrous; he has no money and someone else has his patients. Unfortunately such experiences are not uncommon, and hitherto insurance committees have not felt able to intervene. The Insurance Acts Committee has now received information from the clerks to a number of insurance committees who receive instruction from young practitioners to pay their quarterly cheques to Messrs. X Y Z. To deal with this situation it was reported at the May meeting that there is in process of completion by the Insurance Acts Committee a scheme for the advance of money to suitable applicants somewhat similar to that now working with regard to life insurance. One advantage of such a scheme would be that, as in the case of certain mutual benefit societies, the practice for which the applicant required the loan would be investigated by professional men familiar with such work, and the applicant would have the satisfaction of knowing that his practice is regarded as a bona-fide proposition. The terms of the loan too are not likely to be so onerous.

Arch Supports Again

The decision of the referees as to such supports being splints was discussed by representatives of the Insurance Acts Committee with the Ministry, when it was apparently decided to give up the attempt to define a splint. The object of a definition would of course be to make it clear what the chemist has to supply at the cost of the drug fund. In place of such a definition a list is to be drawn up of certain splints which will come within the category; those not listed will have to be obtained by the patient from a surgical instrument maker, with the help of money, if available, from additional benefit funds. From time to time no doubt additions will be made to the list; the procedure will prevent such difficulties as have arisen in the case of arch supports. Insurance practitioners not infrequently order on a prescription form appliances—e.g., a truss—which are not on the schedule of appliances which may be so ordered. When such a prescription gets to the pricing bureau the insurance committee pays the chemist who supplied the truss and recovers the money to do so from the doctor—who is apparently not permitted to reclaim from the patient. It hardly seems fair that the doctor should bear this expense when, if he had known the appliance was not in the schedule and he had ordered it on a piece of paper, the patient would have had to obtain it and pay for it in the best way he could. This matter also is to be discussed with the Ministry.

Health Insurance in America

Although the American Medical Association is still officially opposed to any form of national health insurance, the Michigan State Medical Society has had before it a recommendation to adopt the principle. The House of Delegates before accepting the recommendation sent its speaker, Dr. H. A. Luce, and Dr. Nathan Sinai, chairman of the committee on medical services, to make a study of the English system. On their report the medical profession in Michigan is now committed to the principle of health insurance provided that its administration is under the control of the medical profession.

[1] THE LANCET, 1933, ii., 1325.

CORRESPONDENCE

THE LATE SIR WALTER FLETCHER

To the Editor of THE LANCET

SIR—The public life of this country suffered a loss of more than common magnitude through the death of Sir Walter Morley Fletcher, K.B.E., M.D., F.R.S., first Secretary of the Medical Research Council, on the 7th June, 1933. He was then in his sixtieth year, and in the height of those powers which he had used without stint in the service of science and of mankind. The ideal that he held before him, in words which were frequently upon his lips, was the advancement of knowledge for the relief of human suffering. He strove ever towards this, both in his years at Cambridge as a brilliant investigator and an influential teacher of youth, and later in the administration of the public support provided for medical research and in measures for bringing the results of scientific work more effectively to the assistance of the State.

Walter Fletcher gave richly to the common weal, and it is proper that some worthy tribute of an enduring kind should be paid to his memory. The desire to take part in this will be widespread among those who were able truly to appreciate his great labours in the cause of medical science, and will be felt not least by the many research workers who were directly indebted to him for help and inspiration: it will extend, also, to others in different spheres of life who were privileged to enjoy that friendship for which he had so great a gift, and throughout a wider circle of those who admired his vigorous personality and his mastery of practical affairs.

It is considered that the tribute should consist in the first place of a personal memorial, and secondly, of the inception of some scheme for the furtherance of the cause which Sir Walter Fletcher had so much at heart. It is therefore proposed first to commission a portrait bust, to be placed in a suitable setting in the entrance hall of the National Institute for Medical Research at Hampstead. The remainder of the sum collected will then be used as a fund for building—at the farm premises of the National Institute at Mill Hill—a Walter Fletcher Laboratory, to be devoted particularly to those nutritional studies in which he was so keenly interested. This will not only provide an appropriate memorial, but it will make an urgently needed contribution to the national equipment for work in what is at present among the most important of all branches of medical research.

In view of the wide utility and public value of the second part of the memorial, it has not been thought desirable to suggest for individual subscriptions any limit such as might have been fitting for a tribute of a purely personal character. It is strongly hoped, however, that this will in no way deter those who may wish to have a share in the personal memorial but are of necessity restricted to giving quite small sums. All subscriptions should be sent to the Secretary, Fletcher Memorial Fund, 38, Old Queen-street, Westminster, S.W.1.

We are, Sir, yours faithfully,

FURUNCLE OF THE AUDITORY MEATUS

To the Editor of The Lancet

Sir,—Every nose, throat, and ear specialist has amongst his patients a number of sufferers from furunculosis of the external auditory meatus. Whilst not dangerous either to life or to hearing, the trouble assumes importance from the fact that the pain is excruciating and calls for immediate relief. My experience has led me to formulate a few "dont's":

1. Don't use hydrogen peroxide.
2. Don't use strong glycerin of carbolic drops.
3. If there is nothing to syringe out in the ear do not syringe.
4. Avoid solutions of mercurochrome.

Hydrogen peroxide does not relieve pain and its use paves the way for other furuncles to develop. Glycerin of carbolic damages healthy skin around the furuncle and renders it more liable to infection. Syringing pushes infective material further into the meatus and gives rise to a deeper and ten times more painful boil. If there is a big mass of cerumen, with or without otomycosis (a trouble very common in the tropics), then it is wise to syringe out the mass after preliminary instillation of warm phenol in paraffin (1 in 400). Mercurochrome colours everything deep red and makes the day-to-day watching of the condition difficult.

I have found the following treatment successful in about 500 cases and can thoroughly recommend it. It consists of the application of an ointment locally, followed by the putting in of drops, preceded by radiant heat.

R 1. Zinc oxid. grs. 90.
Adip. benz. ℥i.

R 2. Hydrarg. perchlor. gr. ½.
Cocain. hydrochlor. grs. 5.
Atrop. sulph. gr. ¼.
Tinct. aconit. ♏v.
Glycerin ℥i.

Take a small mustard spoon and half fill it with the ointment, heat it to boiling-point over a flame, and allow it to cool. With a suitable wooden applicator and sterile cotton-wool dab the still liquid ointment on the furuncle and the parts around until well covered by a thick layer of the ointment. If there is much swelling at the meatal entrance the liquid ointment may be poured in. After three hours apply radiant heat from a lamp at a distance of 30 in. for thirty minutes. Early in the application fill up the ear completely with the drops, leaving them in for at least three minutes. Repeat the radiant heat and drops every six hours. Give internally aspirin grs. 5–10 every four hours and an adalin tablet at bedtime repeated after five hours. After 24 hours swab out the ointment gently with phenol paraffin and re-apply.

Within four days almost all the pain and much of the swelling will have disappeared. Now change the drops to hydrarg. perchor. gr. ¼ in glycerin ℥i night and morning for a fortnight. If there is adenitis, antiphlogistine poultices will quickly bring down the inflammation.—I am, Sir, yours faithfully,

Bombay, May 17th. W. H. Vakeel.

PEPTIC ULCER

To the Editor of The Lancet

Sir,—I should like to make three corrections to the report of my opening speech at the Fellowship of Medicine debate on the treatment of peptic ulcer which appeared in your last issue.

1. Lord Moynihan did not contend ten years ago that an ulcer large enough to be demonstrable by the X rays could not be cured except by operation, but he told me that he had not yet seen radiological evidence that such an ulcer could be cured.

2. All symptoms and radiological signs of an enormous gastric ulcer had disappeared at the end of three months in the test case with which I convinced Lord Moynihan; there has been no recurrence in the ten years which have since elapsed.

3. I did not say that I had never seen perforation after proper medical treatment for a sufficiently long time, but that I had never seen perforation occur in a patient whilst under strict medical treatment.

I am, Sir, yours faithfully,

Arthur F. Hurst.

New Lodge Clinic, Windsor Forest, June 11th.

THE HEALTH OF NURSES IN TRAINING

To the Editor of The Lancet

Sir,—You recently published figures regarding the incidence of illness among nurses at St. Bartholomew's Hospital (The Lancet, Jan. 13th, 1934, p. 91). It may be of interest to record the experiences of the last three years at the Royal Free Hospital.

With a daily average of 125 nurses for the whole period, the average daily deficiency on account of illness was:—

1931	4·78 per cent.
1932	2·21 ,, ,,
1933	1·90 ,, ,,

making 2·9 per cent. average daily deficiency for three years. The incidence of sickness among first year nurses was high in each year and formed 50 per cent. of the total in the three year period, second year nurses accounting for 26 per cent. and third year nurses 24 per cent.

At the Royal Free, as at St. Bart.'s, a high proportion of the illnesses were due to throat infections and their complications; also there was more illness in the winter than in the summer.—I am, Sir, yours faithfully,

Dorothy C. Hare,
Physician to the Royal Free Hospital.

Weymouth-street, W., June 10th.

A GRAVE PROTEST

The Proprietors of The Lancet, Ld.

Dear Sirs,—On page 1254 of The Lancet dated 9/6/34 there is a paragraph about me. It is correct so far as culled from the "Medical Directory" and "Kelly's Directory."

A sine qua non of such a notice is the death of the subject, and I submit to you "I am not dead, never have been, and that I am in no earthly hurry."

In regard to this paragraph I will be glad to hear from you what you mean to do.

I am yours faithfully,

James Taylor.

Ugie House, Keith, Banffshire, June 10th.

⁂ We offer sincere apologies for the sad error which was due to a series of misunderstandings. We are aware of the pain as well as inconveniences which might follow upon such a mistake and hope that no such results in this case have occurred.—Ed. L.

ANAEROBIC CULTURE OF FÆCES

To the Editor of THE LANCET

SIR,—In 1926 a case was sent to me clinically diagnosed as suffering from some bacterial toxæmia. The Ministry of Pensions, with whom I subsequently had some correspondence on the case, stated that no infection had been demonstrated—and in fact my aerobic culture of the fæces showed nothing of importance. But anaerobic culture showed a streptococcal infection, and on a vaccine of this the patient got quite well.

I have examined a number of similar cases since then. One has some points of interest. He was clinically suspected of duodenal ulcer. X ray was negative. Aerobic culture showed a definite streptococcal infection of the fæces. On a vaccine of this the patient improved up to a point, after which this vaccine produced no further improvement. Anaerobic culture of the fæces was then undertaken and showed a definite infection with anaerobic streptococci. The first dose, a vaccine of these, produced a sharp reaction in the patient, and this vaccine led to an immediate and complete cure. During the treatment the patient himself commented on the fact that the second vaccine was doing him far more good than the first.

Another perhaps worth mentioning was a severe case of menorrhagia of puberty resistant to all previous treatment. A bacteriological examination of swabs of vagina and cervix had already been reported negative. Anaerobic culture showed a heavy infection of streptococci. Anaerobic culture of fæces showed the same streptococci, as far as could be presumed from the appearance of the colony. With this evidence in hand X ray examination was undertaken and showed a diseased appendix. The appendix was removed and a vaccine of the anaerobic streptococci was given. A complete cure resulted.

I think these cases are worth reporting to suggest that greater success with vaccines might be obtained if anaerobic culture was more frequently employed in a case suspected of intestinal toxæmia, when aerobic culture is negative or the aerobic vaccine is only partly successful.

I am, Sir, yours faithfully,

C. B. DYSON,

Assistant Bacteriologist, Inoculation Department,
June 11th. St. Mary's Hospital, Paddington.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Arc-Lamp Carbon Duty

IN the House of Commons, on June 4th, when the Finance Bill was being considered in committee, Mr. DAVID GRENFELL moved an amendment to provide that the new customs duty on arc-lamp carbons should be 1*s.* 6*d.* a lb. for carbons exceeding 14 mm. in diameter, instead of 5*s.* as proposed in the Bill. He feared that this high duty would curtail facilities in connexion with hospitals.—Sir PERCY HARRIS supported the amendment. The consulting engineer of St. Bartholomew's Hospital had told him that as a result of long and laborious experiments he had found that the imported article was the only carbon that could be relied on to give perfect treatment without risk or danger to the patient and to the satisfaction of the doctor. It was not, he said, a question of price, because the continental carbon was more expensive; it was bought because it was more satisfactory.

Dr. BURGIN, Parliamentary Secretary to the Board of Trade, said that when this matter was last before the committee (April 26th) the Chancellor of the Exchequer said that before the question came before the House again there would be ample opportunity to consider representations, and on behalf of the Board of Trade he had offered to give attention to any fresh considerations. There had been, in fact, no response to that invitation. It was estimated that arc-lamp carbons taken by hospitals were something under 2 per cent. of the total consumption of carbons. Assurances had been given to the Government that British manufacturers were in a position to supply the whole requirements of the country, and undertakings had been given that the price of British carbons would not be increased. If consumers desired to use foreign carbons they would have to pay the duty on them.

The amendment was negatived by 243 votes to 45.

Children and the Unemployment Bill

In the House of Lords, on June 5th, Lord ROCHESTER, Paymaster-General, moved the second reading of the Unemployment Bill, which has already passed through the House of Commons.—Lord MARLEY said the B.M.A. committee on nutrition had reported that to feed a child of 1 to 2 years of age the minimum sum necessary per week was 2*s.* 8*d.*, for a child of 3 to 6 years 3*s.* 4½*d.*, for a child from 8 to 10 years of age 4*s.* 2*d.* This Bill allowed only 2*s.* Even if they gave a child one pint of milk a day only, and nothing else, that would come to 1*s.* 9*d.* a week. The sum provided in the Bill was, he felt, utterly inadequate, and meant then the continuation of the under-nourishment of children in order to provide for the solvency of the Unemployment Insurance Fund. The Labour party were opposed to this Bill root and branch.—Lord ELTON suggested there was ground for optimism in Sir George Newman's observation that during 1932, in the period of deepest depression, the two most characteristic tests of malnutrition—infantile mortality and deaths from tuberculosis—had not only decreased, but were the lowest on record. Malnutrition undoubtedly existed, and had done so under all Governments, but they hoped that this Bill was likely to decrease it.

Milk-supply and Public Health

In the House of Commons, on June 7th, Mr. ELLIOT, Minister of Agriculture, moved the second reading of the Milk Bill. The main objectives before the Government, he said, were to secure an increased consumption of pure liquid milk in this country, to secure the confidence of the public in the purity of its milk supplies, and thirdly, to hold the position while those two campaigns were got under way by advances for manufacturing milk. The Bill did not refer specifically to the provision of milk in schools, but it had been announced by him in February last that the Government would only make grants in aid of an approved programme of publicity to be submitted by a Milk Marketing Board if the programme contained among other things provision for the supply of milk to schools at reduced rates. That assurance stood. The objections which had been raised to the Bill were, first, that the Government were encouraging the production of milk products in preference to the increase in the consumption of fresh milk, and secondly, that they failed to make adequate provision for the eradication of disease from cattle.

To take the second point first, he was assured by his technical advisers that in the provisions which the Government were now making they were proceeding as rapidly as was reasonable considering the supplies, both of men and money, available for the eradication of disease from our herds. The programme laid down by the Cattle Diseases Committee envisaged a plan covering a considerable length of time. For instance, on pasteurisation they suggested that large municipalities ought to have the right to require that after two years' notice all milk, except sterilised milk, sold within their boundaries which was not derived from herds free from tuberculin should be pasteurised, but that the power to exercise the right should be deferred for three years, making a total of five years before they would consider it was possible to arrange for any large supply of tubercle-free cattle. The Government programme providing for the payments of premiums to attested herds should bring them perhaps a thousand herds in the first year, but the difficulty of providing and maintaining these herds was so considerable that any rapid expansion in the provision of this stock was unlikely.

But quite apart from lack of men and money, a general campaign of slaughter of infected cows in this country was out of the question because of the lack of milk which would ensue. If they were to start on this very big programme they must have the assurance of continuity, and that assurance he thought they had. The cost of carrying out the proposals brought forward by the Opposition for the supply of milk to children in the public elementary schools would be vastly greater than that of the Government's proposals. They had to deal with the stress upon the industry as well as the desirability of providing milk in the schools.

Sir S. Cripps then moved an amendment :—

> That whilst this House is of opinion that the wider distribution of a pure and efficient milk-supply is an urgent necessity, it cannot assent to the Second Reading of a Bill which is designed to encourage the production of milk products in preference to an increase in the consumption of fresh milk amongst the children in public elementary schools and at a price within the reach of the poorer households, and which, in view of the recent report of the Economic Advisory Council, fails to make adequate provision for the eradication of disease from cattle.

In the course of debate Sir Ernest Graham-Little said he would support the amendment because he thought it appeared to offer that practical stimulus to consumption which should precede any other factor in the Bill. The urgency of distributing milk to school-children ought to determine their action that night. There could be no immediate supply if they were to wait for the cleaning up of the herds, which in any case could not be applied to every disease derived from milk. Milk was the best medium for the growth of the tubercle bacillus, and milk tanks were practically uniformly infected with tubercle. People asserted that pasteurisation destroyed the value of the milk, but that was probably an entirely fallacious statement. It was obviously wrong to distribute a product which could cause widespread disease, and must cause it if there was no economical method of rendering that product safe and clean. It had become the opinion of the medical profession that to distribute milk of any kind in the fresh state was unwise. There was freedom from tubercle in tuberculin-tested milk, but no freedom from other infections. He believed that the distribution of milk in bulk, as was now immediately possible, would result in the improvement of nutrition of the children, and at a relatively small expense pasteurisation would secure their safety from any disease infecting that milk.

The amendment was rejected by 190 votes to 47, and the Bill was then read a second time.

Road Accidents

When the Road Traffic Bill was being further considered by a Standing Committee of the House of Commons on June 7th, Mr. Guy moved the following new clause :—

> (1) Where medical or surgical treatment or examination is immediately required as a result of bodily injury (including fatal injury) to any person caused by, or arising out of, the use of a motor vehicle on a road, or in a place to which the public have a right of access, and the treatment or examination so required (in this section referred to as "emergency treatment") is effected by a registered medical practitioner, the owner of the vehicle shall, on a claim being made in accordance with the provisions of the next succeeding section, pay to the practitioner, or, where emergency treatment is effected by more than one practitioner, to the practitioner by whom it is first effected—
>
> (*a*) a fee of twelve shillings and sixpence in respect of each person in whose case the emergency treatment is effected by him ; and
>
> (*b*) a sum, in respect of any distance in excess of two miles which he must cover in order to proceed from the place whence he is summoned to the place where the emergency treatment is carried out by him and to return to the first-mentioned place, equal to sixpence for every complete mile and additional part of a mile of that distance.
>
> (2) Where emergency treatment is carried out in a hospital (that is to say, an institution, not being an institution carried on for profit, which provides medical or surgical treatment for in-patients) the provisions of the foregoing subsection with respect to the payment of a fee shall have effect with the substitution of references to the hospital for references to a registered medical practitioner.
>
> (3) Liability incurred under this section by the owner of a vehicle shall, where the event out of which it arose was caused by the wrongful act of another person, be treated for the purposes of any claim to recover damage by reason of that wrongful act as damage sustained by the owner.
>
> (4) A policy of insurance or a security in respect of third-party risks shall not be deemed to comply with the requirements of Part II. of the principal Act unless the owner of the vehicle to which it relates is specified therein for the purposes of paragraph (*b*) of Subsection (1) of Section 36, or of Section 37 of the said Act, as the case may be, and, notwithstanding anything in the proviso to paragraph (*b*) of Subsection (1) of the said Section 36, any liability which may be incurred under this section by the owner shall be deemed to be a liability required to be covered under that paragraph.

Last year, he said, Parliament provided certain payments to hospitals in the Road and Rail Act, but no provision had been made for emergency treatment by doctors or the hospitals for first aid. The fee of 12*s.* 6*d.* mentioned in the clause was, he thought, a reasonable one. The proposal was that payment should be made irrespective of any question of negligence. His information was that the total cost of this first-aid treatment and the payment in respect thereof would be in the neighbourhood of £250,000, or probably less. This would mean an additional insurance premium of something like 2*s.* 6*d.*

Sir Ernest Graham-Little, speaking for King Edward's Hospital Fund for London and the British Hospitals Association, supported the new clause which, he understood, was to follow the clause at present before the Committee.

Mr. Oliver Stanley (Minister of Transport) said that everybody recognised the great hardships caused to doctors by the additional calls to road accidents and the extreme difficulty they had in getting payment for their services, but it was only right that hon. Members should realise that they were altering the principle that a man was liable only for his own negligence. Up to now the whole of insurance had been on that basis, and he feared the effect of extending it.

The new clause was read a second time by 14 votes to 9 and was added to the Bill. The committee when it met on June 12th agreed to an amendment to this clause proposed by Mr. Stanley providing that liability for payment for emergency treatment should be placed on the user of the vehicle at the time that the accident occurred. It was, he said, advisable to follow the provision of the Act of 1930, which attributed the provision of third party risk to the user and not the owner of a motor vehicle, and not to attach to the owner new and different risks which he was not at present compelled to cover by insurance. Doctors and hospitals, he added, would not suffer in any way by confining their claim to the person using the vehicle at the time of the accident.

A new clause moved by Sir Francis Fremantle providing machinery for the recovery of claims on the part of doctors and hospitals was also read a second time and added to the Bill.

HOUSE OF COMMONS

THURSDAY, JUNE 7TH

Water Shortage in England

Mr. Bernays asked the Minister of Health whether he was in a position to make a statement on the water shortage in England.—Mr. Shakespeare (Parliamentary Secretary to the Ministry of Health) replied : My right hon. friend is advised that the position over a large part of the country, the north and east, Wales and the west and the south-west, as well as part of the Midlands, is generally better than it was a month ago. The south and south-east have not shared in the improvement. He has no reason to think that water undertakers will not be able to meet the situation, provided consumers play their part by reasonable economies in the use of water. The coöperation so far given by them accounts largely for improved conditions. In rural areas with defective supplies, the authorities should expedite measures for permanent schemes, with the grant available under the Rural Water Supplies Act.

Mr. JOEL asked the Minister of Health the number of empty or relatively empty reservoirs now in this country and the towns which normally relied on such reservoirs; and the precautions being taken to safeguard the well-being of the townsfolk affected.—Sir HILTON YOUNG replied: I am not aware of any empty or relatively empty reservoirs. In some areas reserves are seriously low. Active steps have been taken in these areas to conserve supplies, with the coöperation of consumers, and to augment the supplies. Where further powers are necessary these can be obtained expeditiously by procedure under the Water Supplies (Exceptional Shortage Orders) Act recently passed.

Kilmainham Hospital Trust

Captain CUNNINGHAM-REID asked the Financial Secretary to the War Office when it was anticipated that the trust relating to Kilmainham hospital would be closed finally.—Sir FREDERICK THOMSON (Treasurer of the Household) replied: I regret that I am unable to say.

Blood Tests for Inebriates

Mr. HALES asked the Home Secretary if he was aware that in Sweden a blood test was taken of a person charged with drunkenness; and, having regard to the satisfactory results therefrom, if he would consider the desirability of taking steps to introduce the same procedure into this country.—Sir JOHN GILMOUR replied: I am aware of the test to which my hon. friend refers. Evidence derived from a blood test is sometimes given in this country in cases where drunkenness is an element in a criminal charge, but I have no power to require any person to submit to such a test.

Factories Report

Mr. RHYS DAVIES asked the Home Secretary when the report for the last year of the chief inspector of factories and workshops would be issued.—Sir JOHN GILMOUR replied: I hope the report will be issued by the middle of next month.

MONDAY, JUNE 11TH

Doctors' Telephones in Remote Country Districts

Sir ROBERT HAMILTON asked the Postmaster-General what the rental charges would be under the proposed new scale for a doctor's telephone in a country district in Shetland, now charged at £12 per annum.—Sir KINGSLEY WOOD replied: I understand the hon. Member to refer to a subscriber who does not come within the ordinary tariff conditions but pays a specially assessed rental. The question whether any rental reduction can be made in such cases is under consideration.

State Inspection of Private Schools

Mr. ERNEST EVANS asked the Parliamentary Secretary to the Board of Education whether His Majesty's Government accepted in principle the recommendations of the departmental committee on private schools in favour of State inspection of such schools and the acquiring by the State of power to compel the closing of any such schools as might be found to be unsatisfactory; and whether he proposed to introduce legislation designed to effect such objects and, if so, when.—Mr. RAMSBOTHAM replied: As indicated in the answer given on March 29th, 1933, there can be no question of proceeding in the near future with the legislation which would be required to give effect to the main recommendations of this committee. I regret, therefore, that I am not at present able to inform the hon. Member of the views of His Majesty's Government on the various recommendations of the committee.

OBITUARY

GEORG WALTHER GRODDECK

To a circle of friends and patients in many countries the death of Dr. Groddeck, of Baden Baden, in his 68th year, will bring a sense of irreparable loss. It comes at the moment when his methods and philosophy were beginning to attract public attention in England both in the world of medical psychology and in the field of general literature. He brought to his psychotherapeutic works the creative vision of the artist—almost all his early writings were literary works, fiction, poetry, belles-lettres, criticism—as well as long experience with cases of chronic disease of every kind, for his sanatorium at Baden Baden was the refuge of any patient who had been abandoned by others as impossible to help.

Groddeck's earlier methods were based on those of Schweninger, Bismarck's physician, under whom he studied at the university and whom he afterwards assisted in practice. Little use was made of drugs; his regimen included dieting, local applications of heat and deep massage given by the doctor himself. In "Das Buch vom Es" he recounts how the curious symptoms of a patient first led him to realise the influence of unconscious forces in producing disease. He gradually came to the theory of unconscious motivation in every kind of disease, and step by step elaborated a technique of psychotherapy which he tested on all his patients. Massage and heat he never abandoned, but dieting seemed to him less and less important as his psychological work developed. In 1917 the publication of a brochure upon mental factors in the determination of organic disease led to his friendship with Freud, whose work he never wearied of extolling in everything he wrote, and later to his joining the Psycho-Analytical Society, of which Freud was then president. He never however abandoned his independent outlook nor his own developing technique.

Three years ago he suffered from a severe illness which left him physically exhausted, and although he still opened his sanatorium for the summer months each year, it was obvious that the work imposed a heavy strain upon his strength. On Whitsunday he was obliged to give it up and on June 11th he died in his sleep in a sanatorium near Zurich.

WILLIAM SIMMS, L.D.S. R.C.S. Irel., M.Sc. Manch.

THE death was announced recently of Mr. William Simms, a well-known figure in the world of dentistry and at one time dean of the dental school of the University of Manchester.

William Simms was born in 1856 and entered dental practice, as was common 50 or 60 years ago, as an apprentice. Under the Dentists Act of 1878 he was registered as qualified, being recognised at the passing of the Act as engaged in bonâ-fide practice of dentistry, but two years later he obtained by examination the diploma of L.D.S. R.C.S. Irel. He was early to display a scientific interest in the development of his branch of the profession by writing on the uses of cocaine in dentistry, the employment of which as a local anæsthetic was at that time an innovation. He became interested in prosthetic work and recently produced a Manual of Dental Prosthetics, a résumé of his experience throughout a long period, for it was not published till he was over 70 years of age. He was responsible for the shape of the curriculum for the dental degree at Manchester, and as clinical teacher, lecturer, examiner, and dean of the Dental School he was a valuable member of the teaching staff of the University. In 1930 the University conferred on him the degree of Hon. M.Sc.

MEDICAL NEWS

University of Cambridge

On June 8th the following degrees were conferred :—

M.B., B.Chir.—H. T. Cox (by proxy), W. R. Billington, R. V. Payne, H. D. White, William Wilson, and J. L. Parker.

B.Chir.—E. J. Neill and W. E. Tucker (by proxy).

The title of the degree of M.D. has been conferred on Mrs. A. G. Dauncey.

University of London

At recent examinations the following candidates were successful :—

THIRD EXAMINATION FOR M.B., B.S.

Honours.—(*a*) R. H. R. Belsey, St. Thomas's Hosp.; (*a, d*) E. W. Bintcliffe, St. Bart.'s Hosp.; (*b, d*, University Medal) Edith J. R. Browne, Roy. Free Hosp.; (*b*) A. M. R. Cann, Middlesex Hosp.; (*e*) D. R. Davies, Univ. Coll. Hosp.; (*e*) R. R. Henderson, St. Thomas's Hosp.; (*a*) E. G. Jones, St. Bart.'s Hosp.; (*a*) L. E. Jones, St. Thomas's Hosp.; (*b*) Beryl Twyman, Univ. Coll. Hosp.; and (*e*) Sylvia V. F. Wolfe, Roy. Free Hosp.

(*a*) distinguished in medicine; (*b*) distinguished in pathology; (*d*) distinguished in surgery; (*e*) distinguished in obstetrics and gynæcology.

Pass.—Mary A. C. Adams, Roy. Free Hosp.; J. L. Bates, Guy's Hosp.; Mary A. M. Bigby, Roy. Free Hosp.; Eileen A. Chennell, St. Mary's Hosp.; J. A. Chivers, St. Bart.'s Hosp.; J. G. R. Clarke, St. Thomas's Hosp.; Doris Cohen and Beryl D. Corner, Roy. Free Hosp.; C. F. Critchley, St. Thomas's Hosp.; E. A. Danino and D. M. Dean, St. Bart.'s Hosp.; C. B. Dharmasena, Ceylon Med. Coll. and St. Bart.'s Hosp.; Israel Doniach, Univ. Coll. Hosp.; O. G. Edholm, St. George's Hosp.; R. T. Elven, Guy's Hosp.; Nancie I. Faux, Roy. Free Hosp.; Constance E. Field, Univ. Coll. Hosp.; J. M. Flower, Westminster Hosp.; H. E. D. Gale, St. Bart.'s Hosp.; C. J. Gavey, London Hosp.; Nathan Green and J. T. Griffiths, Univ. Coll. Hosp.; Hilary Gunton, Roy. Free Hosp.; R. M. Haines, Westminster Hosp.; S. T. Hayward, St. Bart.'s Hosp.; Alice M. Head, Roy. Free Hosp.; G. F. Henderson, Univ. Coll. Hosp.; E. F. Hewlitt, Guy's Hosp.; A. C. Howard, Univ. Coll. Hosp.; H. C. Hugh, St. Bart.'s Hosp.; N. M. Jacoby, Guy's Hosp.; Elizabeth M. James, Roy. Free Hosp.; Margaret H. James, Univ. Coll. Hosp.; H. W. E. Jones and W. S. G. Lawson, St. Thomas's Hosp.; H. B. Lee, St. Bart.'s Hosp.; Rosamund M. I. Mackay, Univ. Coll. Hosp.; G. A. Mais, St. Thomas's Hosp.; S. P. Mason and P. H. Nankivell, Middlesex Hosp.; Doris E. Oxford, Roy. Free Hosp.; Harold Royle, St. Bart.'s Hosp.; G. C. Sawyer, Guy's Hosp.; Margaret H. Scott, Roy. Free Hosp.; Charlie Seeley, St. Mary's Hosp.; H. L. Selwyn and Ralph Shackman, St. Bart.'s Hosp.; J. V. Shemilt and D. G. Snell, St. Thomas's Hosp.; W. P. Stamm, Guy's Hosp.; M. G. Stratford, Univ. Coll. Hosp.; Mary G. Tate, Roy. Free Hosp.; W. P. McK. Telfer, St. Bart.'s Hosp.; T. P. Thamotheram, Ceylon Med. Coll. and King's Coll. Hosp.; Elisabeth J. McQ. Thomas, A. S. Thorley, and W. W. Walther, Univ. Coll. Hosp.; S. H. Wass, Guy's Hosp.; and Elizabeth B. White, Roy. Free Hosp.

The following students have passed in one of the two groups of subjects :—

Group I.—S. H. Alavi, St. Thomas's Hosp.; G. W. Bender, St. Mary's Hosp.; D. M. Blomfield, St. Bart.'s Hosp.; J. A. Brocklebank and I. A. Cathie, Guy's Hosp.; Enid S. Davies, Univ. Coll. Hosp.; Audrey P. Dence, Roy. Free Hosp.; D. G. ff. Edward, St. Bart.'s Hosp.; Evelyn J. Forgan, Roy. Free Hosp.; W. T. J. Fowler, Guy's Hosp.; Joan I. Franklin-Adams, Roy. Free Hosp.; D. B. Hyslop, Charing Cross Hosp.; A. D. Iliff and F. A. Jones, St. Bart.'s Hosp.; Margaret M. C. Louden, Roy. Free Hosp.; J. I. Maran, Univ. Coll. Hosp.; G. D. Morgan, Charing Cross Hosp.; Barbara G. Morton, Roy. Free Hosp.; F. E. Norris, London Hosp.; D. S. Piper, Guy's Hosp.; Irene E. Sandford, Roy. Free Hosp.; K. G. Seager, St. Mary's Hosp.; H. W. G. Staunton, St. Bart.'s Hosp.; D. L. McK. Stewart, King's Coll. Hosp.; H. A. Thomas, Univ. Coll. Cardiff and Univ. Coll. Hosp.; Sarah C. B. Walker, Roy. Free Hosp; and M. E. Wigfield, St. Thomas's Hosp.

Group II.—H. H. Atkinson, Univ. Coll. Hosp.; E. A. Bisson, London Hosp.; Muriel Boycott, Univ. Coll. Hosp.; D. J. T. Brinkworth, Middlesex Hosp.; Robert Bruce, King's Coll. Hosp.; Ronald Carpenter and R. F. Clarke, St. Bart.'s Hosp.; C. W. J. Claydon, *King's Coll. Hosp.; D.* W. A. Degazon, Univ. Coll. Hosp.; Lynette Dowsett, Roy. Free Hosp.; H. D. Fairman, London Hosp.; E. D. Falconer, Guy's Hosp.; T. F. R. Griffin, St. Mary's Hosp.; A. W. J. Houghton, St. Bart.'s Hosp.; Joyce B. Jewson, Roy. Free Hosp.; W. L. Kerr and G. A. Kiloh, King's Coll. Hosp.; J. R. Kingdon and K. A. Latter, St. Bart.'s Hosp.; Sidney Lee, Westminster Hosp.; C. F. Mayo-Smith, St. George's Hosp.; R. H. Purnell and D. C. Reavell, St. Bart.'s Hosp.; J. D. Richardson, King's Coll. Hosp.; A. T. Roden, St. Bart.'s Hosp.; Catherine L. Simmons, Roy. Free Hosp.; B. W. Smith, Guy's Hosp.; M. C. L. Smith, St. Bart.'s Hosp.; E. J. Somerset, King's Coll. Hosp.; W. H. C. Spooner, St. Mary's Hosp.; K. F. Stephens, St. Bart.'s Hosp.; Margaret E. Sutherland, Roy. Free Hosp.; R. E. Thomas, Univ. Coll. Hosp.; W. F. Townsend-Coles, London Hosp.; R. J. Vakil, St. Thomas's Hosp.; and E. C. Zorab, Guy's Hosp.

University of Sheffield

The title of emeritus professor has been conferred on Dr. Edward Mellanby, F.R.S., secretary to the Medical Research Council, and formerly professor of pharmacology in the University.

Mr. John Keall has been re-elected president of the Pharmaceutical Society of Great Britain for another year.

THE Department of Health for Scotland state that from June 25th the headquarters of the dental officer for Scotland will be transferred to 136, Renfield-street, Glasgow, C.2.

University of Wales

The Cecil Prosser research scholarship (value £250) will shortly be awarded for research in the department of tuberculosis. Further particulars will be found in our advertisement columns, and applications should reach the registrar at the University Registry, Cathays Park, Cardiff, not later than Sept. 1st.

Scottish Board of Control

Dr. William N. J. Chapman has been appointed a deputy commissioner of the General Board of Control for Scotland. Dr. Chapman is at present assistant medical officer to the Lanark district asylum, Hartwood.

Anti-Noise League

A conference will be held by this league in University College, Oxford, from July 13th to 16th under the chairmanship of Lord Horder. The work of the conference has been arranged under four heads: Dr. William Collier is chairman of the health and noise group and the speaker is Dr. Dan McKenzie, while Sir James Purves-Stewart will preside over the science and noise group and Dr. G. W. C. Kaye will speak. During the conference an exhibition will be held displaying noise-measuring instruments, noise-abatements appliances, and examples of sound-proofing and absorption, &c. The secretary of the league may be addressed at 18, Old Cavendish-street, London, W.1.

Cancer Hospital (Free), London

In March, 1933, the International Cancer Research Foundation, established by Mr. William H. Donner of Philadelphia, awarded a sum of £1000 per annum for a period of two years to the research institute of this hospital in support of investigations into factors which underlie the origin of malignant growths. This grant has provided two research scholarships, which are held by Mr. G. A. D. Haslewood, M.Sc., who is working with Mr. J. W. Cook, D.Sc., and by Miss Edna Roe, B.Sc., who is studying the molecular structure of carcinogenic compounds by physical methods under Mr. W. V. Mayneord, M.Sc., in the physics section of the radiological department of the hospital. Under the direction of Mr. Cook, Mr. Haslewood has recently prepared a very active cancer-producing compound, methylcholanthrene, from another compound, deoxycholic acid, which is known to occur in the human body. To assist in further developments of this work the trustees of the foundation have decided that this grant shall be continued for an additional three years.

British Social Hygiene Council

The summer vacation school in connexion with this council will be held at Digswell Park Conference House, Welwyn Garden City, from Monday, June 25th, to Saturday, June 30th. The programme is designed to present the scientific background of social hygiene as a coherent whole and will consist of three courses, of five lectures each, on (1) anthropology, by Dr. Raymond Firth, lecturer on the subject at the London School of Economics; (2) biology, by Mr. D. Ward Cutler, deputy-director, Rothamsted; and (3) psychology, by Prof. A. E. Heath, professor of philosophy, Swansea. The lectures will deal with the fundamental principles of the subjects as related to the problems of daily life both at home and abroad. It is hoped that magistrates, clergy, doctors, and probation officers will take advantage of this opportunity of studying the scientific bases of marriage and their bearing on conjugal relationships. The vacation school will be inaugurated by an address from Prof. F. A. E. Crew, director of the Institute of Animal Genetics at Edinburgh. In connexion with the school the membership fee is a guinea and the boarding fee £2 7*s.*, while railway fares are those of the summer tickets now in force. Various facilities are being provided for recreation and amusement free of charge, and information on these and other subjects may be obtained from Miss Grant, Secretary, British Social Hygiene Council, Carteret-street, London, S.W.1.

Appointments

Bown, D. G., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory and Workshop Acts for Clacton, Essex.

Goddard, Charles E., O.B.E., M.D. Durh., T.D., whole-time Medical Officer to the enlarged district of Wembley.

Orley, Alexander, M.D. Geneva, D.M.R.E. Camb., Honorary Assistant Radiologist to the West End Hospital for Nervous Diseases.

London County Council Hospital Staff.—The following appointments, promotions, and transfers are announced. A.M.O. (I.) and (II.) = Assistant medical officer, Grades I. and II. Temp. = temporary.

Leslie, W., M.B., F.R.C.S., Senior A.M.O. (II.), St. Stephen's.

Clough, G. M., M.B., Ch.M. Sydney, M.R.C.P. Lond., Temp. A.M.O., St. James's.

Critchley, C. F., M.R.C.S. Eng., Clinical Assistant, St. Giles.

James, M. F., M.B. Lond., House Physician, Queen Mary's Hospital for Children.

McDade, R. S. C., M.B. Camb., A.M.O. (I.), High Wood Hospital for Children.

Murray, M. G., M.B. Aberd., A.M.O. (I.), St. George-in-the-East.

Macdonald, C. R., F.R.C.S., M.B. Edin., A.M.O. (I.), St. Leonards.

Brown, W., M.B. N.Z., A.M.O. (II.), New End.

Rutter, T. E., M.B. Edin., A.M.O. (II.), Highgate.

Kaines, G. E., M.B. Melb., A.M.O. (II.), Dulwich.

Evans, J. G., M.R.C.S. Eng., A.M.O. (II.), Fulham.

Cardwell, E., L.R.C.P. Edin., A.M.O. (II.), St. Benedict's.

Avery, J. C. H., M.B. Lond., A.M.O. (I.), Queen Mary's Hospital for Children.

Devlin, W. L., M.B. Belf., A.M.O. (II.), Norwood Hospital for Children.

O'Sullivan, J. A., M.D. Dubl., A.M.O. (I.), St. Peter's.

Wright, E. M., B.M. Oxon., A.M.O. (I.), Brook.

Young, B. A., M.D., M.R.C.P. Lond., Senior Assistant Medical Officer (I.), St. Peter's.

Spurgin, P. B., M.R.C.S. Eng., Temp. Visiting Medical Officer, St. Marylebone Institution.

Vacancies

For further information refer to the advertisement columns

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

Bagdad. Royal College of Medicine.—Chair of Materia Medica. Salary at rate of I.D. 960 to I.D. 1200 per annum.

Birmingham Children's Hospital.—Res. Surg. O. £175.

Birmingham City.—P.H. Dept., Sen. Asst. M.O. for Tuberculosis Section. £750.

Blackburn Roy[illegible] O. £150.

Bolton Royal I[illegible]

Bradford Child[illegible] st. Surgeon.

Brighton, Royal Sussex County Hospital.—Two Hon. Med. Regs., Three Hon. Surg. Regs., and Hon. Dermatological Clin. Asst.

Bristol Eye Hospital.—Asst. Res. H.S. At rate of £100.

Bristol General Hospital.—Sen. Res. M.O. £200. Cas. H.S. At rate of £100. Also Two H.P.'s., Two H.S.'s., Res. Obstet. O., and H.S. to Spec. Depts. Each at rate of £80.

Bristol, Winford Orthopædic Hospital.—Hon. Dental Surgeon.

Cardiff, University College of South Wales and Monmouthshire.—Asst. Lecturer in Anatomy. £400. Asst. Lecturer in Physiology. £400. Asst. Lecturer in Histology. £300.

Cardiff, Welsh National School of Medicine.—Part-time Demonstrator in Materia Medica, &c. At rate of £50.

Central London Ophthalmic Hospital, Judd-street, W.C.—Sen and Jun. H.S.'s. £120 and £100 respectively.

Charterhouse Rheumatism Clinic, Crosby Row, Long-lane, S.E.—Two Hon. Clin. Assts.

Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £150.

Colchester, Essex County Hospital.—H.P. £150.

East Ham Memorial Hospital, Shrewsbury-road, E.—Hon. Ophth. Surgeon.

Exeter, Royal Devon and Exeter Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Folkestone Royal Victoria Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £150 and £120 respectively.

Gloucestershire Royal Infirmary, &c.—H.P. and H.S. Each at rate of £150.

Great Yarmouth General Hospital.—H.S. £140.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. At rate of £100.

Hull Royal Infirmary.—Cas. O., also Third H.S. Each at rate of £150.

Ilford, King George Hospital.—Cas. O. £130.

Indian Medical Service.—Commissions.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. £120.

King's College Hospital, Denmark Hill, S.E.—Hon. Radiologist.

Liverpool, Alder Hey Children's Hospital.—Res. Asst. M.O. £200.

Liverpool, City Infectious Diseases Hospitals.—Asst. Res. M.O. £200.

London Homœopathic Hospital, Great Ormond-street, Bloomsbury, W.C.—Res. M.O. At rate of £100.

London Jewish Hospital, Stepney Green, E.—Hon. Surgeon.

London University.—Examinerships.

Manchester, Christie Hospital and Holt Radium Institute, Withington.—Res. M.O. At rate of £150.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Metropolitan Hospital, Kingsland-road, E.—Cas. O. At rate of £100.

Middlesex County Council.—Tuberculosis M.O. £750.

Ministry of Health.—Two Medical Officers. Each £833.

Nelson Hospital, Merton, S.W.—Res. H.S. At rate of £100.

Newcastle-upon-Tyne Hospital for Sick Children.—Res. Surg. O. £250.

Newcastle-upon-Tyne Royal Victoria Infirmary.—Two Anæsthetists to Leazes Hospital. Each at rate of £100. Also H.P.'s and H.S.'s to Special Depts. Each at rate of £50.

New Zealand, Wellington Hospital Board.—£1100.

Northampton General Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Norwich, Norfolk and Norwich Hospital.—H.S. to Spec. Depts. £100.

Nottingham Children's Hospital.—Res. H.S. At rate of £150.

Portsmouth Royal Hospital.—H.P. and H.S. Each at rate of £130.

Preston County Mental Hospital, Whittingham.—Jun. Asst. M.O. £500.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P., and H.S. Each at rate of £125.

Prince Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.P. and H.S. Each at rate of £100.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Two Res. Anæsthetists. Each at rate of £100.

Queen's Hospital for Children, Hackney, E.—Surgeon for Ear, Nose, and Throat Dept.

[illegible] -H.S. £150.

[illegible] *Park, W.*—Res. M.O. £300.

[illegible] £250.

Salford Royal Hospital.—Dist. M.O. for Pendleton Area. £200.

Scarborough Hospital and Dispensary.—H.S. At rate of £175.

Sheffield Children's Hospital.—H.S. Also H.P. Each at rate of £100.

Shrewsbury, Royal Salop Infirmary.—Cas. O. and Res. Anæsthetist. At rate of £160.

Smethwick County Borough.—Asst. M.O.H. and Asst. School M.O. £500.

Southampton, Royal South Hants and Southampton Hospital.—H.P., Cas. O., Res. Anæsthetist, and H.S. for Ear, Nose, and Throat Dept. H.S. Each at rate of £150. Also Sen. H.S. £200.

Southend-on-Sea General Hospital.—Hon. Visiting Obstet. and Gynæcological Surgeon.

Stamford, Rutland and General Infirmary.—H.S. At rate of £200.

Stockport Infirmary.—H.S. £150.

Tunbridge Wells, New Kent and Sussex Hospital.—Res. Surg. O. £250. Sen. H.S. £175. Second H.S. £150. Also Jun. H.S. £125.

Wales University.—Cecil Prosser Research Scholarship. £250.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.

West Bromwich, Hallam Hospital.—Res. H.P. At rate of £200.

Wigan Royal Infirmary.—H.S. At rate of £150.

Willesden General Hospital, N.W.—Cas. O. and H.S. Each at rate of £100. Also Clin. Assts. to Out-patients' Dept.

Wolverhampton Royal Hospital.—H.S. for Orthopædic and Fracture Dept. At rate of £100.

Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—H.P. and H.S. Each at rate of £100.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Carluke, Lanark; Warrington, Lancs; Torrington, Devon; and at Chesham, Bucks.

A vacancy for a Medical Referee under the Workmen's Compensation Act for the Great Malvern, Hay, Hereford, Ledbury, and Leominster County Court Districts is announced. Applications should be addressed to the Private Secretary, Home Office, Whitehall, London, not later than July 3rd.

Births, Marriages, and Deaths

BIRTHS

Heely.—On June 3rd, at Chudleigh, Devon, the wife of Dr. W. J. Heely, of a daughter.

Jamieson.—On June 8th, at Ventnor Villas, Hove, Sussex, the wife of A. M. de la M. Jamieson, M.B., Ch.B., of a son.

Panting.—On June 7th, the wife of L. J. Panting, B.Ch., St. Olaves, Bradford-on-Avon, of a daughter.

Roberts.—On June 3rd, at Staunton Lodge, Kingsbridge, Devon, the wife of Dr. W. H. Roberts, of a son.

MARRIAGES

Wandless—Rees.—On June 9th, at the Congregational Church, Witham, Essex, Denis J. Wandless, L.D.S., R.C.S. Eng., to Dorothy Mary Rees, daughter of the late Rev. J. Gilbert Rees and Mrs. W. J. Perry, of Little Braxted Hall, Essex.

Wicksteed—MacGregor.—On June 8th, at Carnwath, Lanarkshire, Dr. O. H. Wicksteed to Jean C. MacGregor, M.A.

Williamson—Madden.—On June 9th, at All Saints, Hove, James Charles Frederick Lloyd Williamson, F.R.C.S., to Helen Francis, third daughter of Captain and Mrs. C. H. Madden, of "Sussex Lodge," Shoreham.

DEATHS

Holford.—On June 11th, at "Ravensdene," Sutton, Surrey, Walter Stanley Holford, M.R.C.S., L.R.C.P., L.D.S., aged 67.

Twining.—On June 6th, at Wood End, Ryde, I.W., Vincent Wing Twining, M.B., C.M., late of Salcombe, S. Devon, in his 74th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

FRACTURE OF THE NECK OF THE FEMUR

THE three-flanged nail designed by Smith-Petersen for accurate retention of the fragments in fracture of the neck of the femur is enjoying a large measure of popularity in surgical clinics almost throughout the world. The great advantages of the Smith-Petersen method as compared with other forms of internal splinting are first the very firm hold secured by the blades of the nail, which altogether prevents rotation of the fragments, and secondly the firm impaction obtained by hammering over the great trochanter with the nail already retaining the fracture in the reduced position. Dr. Thomas King, while aware of all these advantages, points out (Med. Jour. Australia, Jan. 6th, 1934, p. 5) that the wide exposure of the joint which has been found necessary by most surgeons for accurate introduction of the nail is the one great objection to its use. He has, therefore, in the University of Melbourne, worked out a technique by means of which the Smith-Petersen nail can be introduced with precision along the neck of the femur through the fracture and into the head of the bone by what is practically a subcutaneous operation. The essentials of the method are (*a*) that there should be complete reduction of the deformity, (*b*) that the vertical neck-shaft angle and the forward (or backward) torsion of the neck of the femur in the reduced position must be known before introduction of the nail, while (*c*) a nail is used which is pierced through its centre and is introduced by threading it along a wire previously inserted in the bone as a guide.

The reduction of the fracture takes place by traction on an orthopædic table, both lower limbs being fixed in extension, equally abducted at an angle of 60°–90°. External rotation is corrected by forward thrust of the greater trochanter by the hand, and the foot-piece is adjusted to maintain the corrected position. A Kirschner wire is introduced, with proper aseptic technique, 2 inches below the tip of the great trochanter and on its posterior aspect. It is pushed inwards close to the posterior aspect of the neck of the femur, midway between its upper and lower borders, until the end of the wire strikes the fracture site. Direct vision through a fluorescent screen is used to guide the wire at the correct level and to negotiate it past the fracture up to the acetabular rim. The wire thus introduced acts as an indication to the direction of the neck of the bone and to the angle at which it joins the shaft. A second wire is now introduced by the special drill used for inserting Kirschner wire, and is made to take the precise direction desired for the subsequent insertion of the nail. It is drilled into the bone about an inch further than the first wire, but not further at first than 4 inches, in case it should enter the pelvis. X ray pictures taken in two planes determine the direction and the depth of penetration of the wire. If necessary the wire can be drilled further, for it must obtain a good hold on the head of the bone.

If the position of the wire relative to the head and neck of the femur is satisfactory, the insertion of the nail is proceeded with. A starter (which is an abbreviated but strong nail) is first used to make the insertion of the Smith-Petersen nail easier, and to prevent damage to its blades. The starter is slipped off the wire and the nail slipped over. The depth of introduction is known from the length of wire previously used. Once the nail has entered the head of the bone, traction on the limb is relaxed, the Smith-Petersen impactor is slipped over the nail head, and its outer end is hit with gentle and repeated blows to drive the ends of the fracture into one another. The wound is sutured and the dressing secured with mastic gum. Weight extension of about 10 pounds is used with the limb supported on a sling or splint. At the end of six weeks the patient may walk on a calliper splint, or, alternatively, earlier weight-bearing may be allowed by the use of a short spica bandage of plaster-of-Paris round the pelvis and thigh. Seven patients have been treated by this special technique, but as a few weeks only had elapsed since operation no pronouncement is possible on its ultimate effect. Judging by the known success of internal fracture by the Smith-Petersen nail, a high proportion of good results is anticipated.

Mr. B. H. Burns has evolved a method similar in principle, and has used it in 12 cases (Proc. Roy. Soc. Med., March, 1934, p. 581). Three Kirschner wires are inserted through an incision over the outer aspect of the greater trochanter, each wire being passed through the neck into the head of the bone in what appears to the operator to be the most suitable direction. A radiogram is taken to show which wire is most accurately placed, and the Smith-Petersen nail is passed over the wire and driven home. The other wires are then extracted.

NATIONAL BABY WEEK COUNCIL

IN its annual report for 1933, the seventeenth year of its existence, the National Baby Week Council records an increase of activity and influence. Since baby shows appear to be gaining in popularity, it is satisfactory to learn that the majority of them are conducted in accordance with the Council's regulations, the chief of which is that judging must be carried out by medical practitioners well qualified in the examination of infants and young children. During the year for the first time the Council added a "talkie" to its list of films, bringing the total up to twelve. A display of propaganda films given in the Kingsway Hall was attended by 2500 people. The overseas work is one of the Council's most useful activities. Largely through the Imperial Baby Week Challenge Shield the movement is spreading to more and more parts of the Empire, and is including in its scope some of those remote districts peculiarly in need of education.

The special subject advocated for propaganda this year is "The Making of an A 1 Nation," with particular emphasis on the importance of good nutrition for expectant and nursing mothers, infants, and toddlers. Baby Week is, as usual, being celebrated in the first week of July, and the National Conference on Maternity and Child Welfare is to be held in the Town Hall, Birmingham, from July 3rd to 5th.

MENINGITIS DUE TO GÄRTNER'S BACILLUS

A CASE of purulent meningitis attributed to the *Bacillus enteritidis* of Gärtner is described by H. G. Rupert (Nederl. tijdschr. v. geneesk., 1934, lxxviii., 1763). The patient, aged three months, and previously healthy, was brought to hospital with a history of convulsions for one week, accompanied by fever. On examination it was found that Kernig's sign was strongly positive, the anterior fontanelle was bulging and tense, the reflexes were somewhat accentuated, the ears and throat normal. The temperature was normal, but after admission rose to 104·5°, remaining high until the fifth day, when death took place, shortly before which the temperature fell to 99°. The pulse-rate remained at about 160 throughout. Lumbar puncture showed that the cerebro-spinal fluid was under great pressure and turbid, and contained numerous polymorphonuclear leucocytes and masses of Gram-negative bacilli, which on further examination were found to be *B. enteritidis*. The same organism was grown from the fæces, but none were found in the blood or urine. The blood-serum was found to agglutinate the patient's own organisms in a dilution of 1 : 250, and another strain of Gärtner's bacillus in a dilution of 1 : 50. The fæces of the other members of the household were examined, but the organism was not discovered. The child's father was a butcher, and it is suggested that he, through being in contact with infected meat, may have been the source of the infection.

Gärtner's bacillus as a cause of suppurative meningitis was reviewed in our columns last November by Dr. F. H. Stevenson and Dr. L. K. Wells (THE LANCET, 1933, ii., 1084), who reported a case of their own. In many of the reported cases the condition has been preceded by some other manifestation such as cholecystitis or cystitis due to this organism. The exact path of infection in the present case remains obscure.

POST-GRADUATE OPPORTUNITIES IN HUNGARY

ON behalf of the Hungarian Medical Postgraduate Committee, Dr. Joseph Baló has sent us the third edition he has brought out of an official guide-book to the medical faculties of Hungarian universities and the public hospitals of Budapest. There are 4520 beds at the service of medical and postgraduate training, and in addition 21,534 hospital beds in large public hospitals where teaching and scientific work is also carried out. Prof. Emil de Grósz is president of the postgraduate committee, and all the teaching is conducted in English, German, or French. The universities which offer opportunities are at Budapest, Szeged, Pécs, and Debrecen; there is also the Apponyi Polyclinic and the hospital of the Jewish community of Pest. A few years ago three important medical institutions were opened almost at the same time: the Institute of Biological Research at Tihany, the State Hygiene Institute promoted with a grant from the Rockefeller Foundation, and the central hospital of the National Institute for Social Insurance. Foreign physicians are invited to call at the headquarters of the Hungarian Medical Postgraduate Committee, VIII. Mária-utca, 39, Budapest.

ROSE DE MAI

A RECENT editorial article upon Natural Perfumes (THE LANCET, June 2nd, p. 1181) aroused some doubt as to what plant is known as rose de mai, which the following information received from Monsieur Moutet answers. Rose de mai is imported from Bulgaria and the name is unlikely to be found in any dictionary. The hawthorn is useless from the point of view of the perfumer. A May scented rose perfume is obtained by the use of synthetic essences. The species of rose de mai used is *R. centifolia.*

LINES FROM A G.P.

Dr. JOHN WISHART writes: "If Dr. F. C. Nicholls gets a book called 'Life,' written—curious to say —by Dr. W. Nicholl, and published in *1841*, he will find therein the whole of 'Lines from a G.P.' It is also to be found, in full, in 'A Whiff of Old Times,' published by Wright of Bristol."

THE LÖWENSTEIN-JENSEN CULTURE MEDIUM.—Dr. Evelyn M. Holmes writes: "May I correct an erroneous impression given in the report of my remarks at the Congress of the Royal Institute of Public Health (THE LANCET, May 26th, p. 1139). I did not say that *sputum*, but pleural, ascitic, and other fluids, even urine on occasion, will give pure cultures on the medium I described for tubercle work without any previous treatment. It is possible that portions of purulent sputum would do so but I have never tried it. Such sputum would probably be microscopically positive and hence not call for culture, unless for the interest of typing."

SCHOOL OF DIETETICS.—The Royal Infirmary of Edinburgh is opening a new school of dietetics in September, 1934, and there are vacancies for students in September, 1934, and April, 1935. The course lasts two years for State-registered nurses and one and a half years for students with two years' domestic science training. It is expected that hospitals inaugurating dietetic departments will send selected nurses from their staff to attend the course. Particulars may be had from the lady superintendent of nurses at the infirmary.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, June 19th.—5.30 P.M., General Meeting of Fellows.

THURSDAY.

Dermatology. 5 P.M. (Cases 4 P.M.) Dr. J. E. M. Wigley: 1. Prurigo. Sir Aldo Castellani: 2. Tinea Imbricata (Tokelau)—previously shown. Dr. Robert Klaber: 3. Sarcoid.

FRIDAY.

Obstetrics and Gynæcology. 8.15 P.M. Registrar's Pathological Meeting. Mr. David M. Currie: Cervical Myoma. Cæsarean Section: Myomectomy. Miss E. M. Shippam: Chorion Epithelioma of Uterus Clinically Simulating Ruptured Ectopic Pregnancy. Mr. John Beattie: Uterus and Ovaries Removed for Chorion Epithelioma on the Evidence of Aschheim-Zondek Reaction. Mr. David M. Stern: Pregnancy and Labour after Hypophysectomy with Reference to Aschheim-Zondek Reaction. Mr. Arthur C. Bell: Round-celled Sarcoma involving Cervix and Corpus Uteri and Fallopian Tubes. Mr. Douglas MacLeod: Botyroid Sarcoma of Cervix Uteri. Mr. R. K. Bowes: Bilateral Cortical Necrosis of Kidneys. Pregnancy Toxæmia. Mr. W. C. W. Nixon: Uterus. Hysterectomy for Conceale[illegible] rhage. Mr. W. R. Winterton: [illegible] a Fallopian Tube Implanted for [illegible]

SATURDAY.

Disease in Children. Summer Meeting at Oxford by invitation of Mr. G. R. Girdlestone. Train leaves Paddington 12.15 or 12.30 P.M. 2.20 P.M., Demonstration of medical and surgical cases at the Wingfield Morris Orthopædic Hospital. Return train arrives Paddington 7.28 P.M.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Manson House, 26, Portland-place, W.

THURSDAY, June 21st.—8.15 P.M., Annual General Meeting, followed by a paper by Dr. L. W. Hackett, Assistant-Director of the International Health Division, Rockefeller Foundation, on the Present Status of our Knowledge of the Races of *Anopheles maculipennis.* There will be a demonstration illustrating the subject at 7.45 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 18th, to SATURDAY, June 23rd.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Afternoon Course in Venereal Disease.—PRINCE OF WALES'S HOSPITAL, Tottenham, N. All-day Course in Medicine, Surgery, and the Specialties.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Lecture-demonstration on Renal Insufficiency, at 2.30 P.M., on Tues. by Dr. Clark-Kennedy.—PANEL OF TEACHERS. Individual clinics in various branches of medicine and surgery are available daily. Courses of instruction, clinics, &c., arranged by the Fellowship of Medicine are open only to Members and Associates.

NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W.

THURSDAY, June 21st.—9 P.M., Dr. Robert Hutchison: Praise and Dispraise of Doctors. (Macalister Lecture.)

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

Daily, 2 P.M., Medical and Surgical Clinics, Operations.

MONDAY, June 18th.—10 A.M., Medical Wards. Pathological Demonstration. 11 A.M., Surgical Wards. 2 P.M., Gynæcological and Surgical Wards, Eye and Gynæcological Clinics.

TUESDAY.—10 A.M., Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Throat, Nose, and Ear Clinic. 4.15 P.M., Lecture, Mr. Green-Armytage: Sterility.

WEDNESDAY.—10 A.M., Medical and Children's Wards, Children's Clinic. 2 P.M., Eye Clinic.

THURSDAY.—10 A.M., Neurological and Gynæcological Clinics. 11.30 A.M., Fracture Demonstration. 2 P.M., Eye and Genito-urinary Clinics.

FRIDAY.—10 A.M., Skin Clinic. 12 noon, Lecture on Treatment. 2 P.M., Throat Clinic. 4.15 P.M., Lecture, Dr. Owen, The New-Born Infant.

SATURDAY.—10 A.M., Medical and Surgical Wards, Children's and Surgical Clinics. The lectures at 4.15 P.M. are open to all medical practitioners without fee.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham.

WEDNESDAY, June 20th.—4 P.M., Mr. V. Z. Cope: Demonstration of Surgical Cases.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, June 19th.—3.30 to 5 P.M. (at the General Hospital), Mr. Beatson Heard: Demonstration of Ophthalmic Cases.

FRIDAY.—3.30 to 5 P.M. (at the Queen's Hospital), Mr. J. N. Sankey: Demonstration of Physiotherapeutic Measures in Surgical Cases.

LEEDS GENERAL INFIRMARY.

TUESDAY, June 19th.—3.30 P.M., Dr. Moll: Demonstration of Medical Cases.

ADDRESSES AND ORIGINAL ARTICLES

PRAISE AND DISPRAISE OF DOCTORS[*]

BY ROBERT HUTCHISON, M.D., F.R.C.P. Lond.
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL

WE are met to perpetuate the memory of Sir John MacAlister. Although not himself a medical man MacAlister did a great work for our profession by the leading part he took in the amalgamation of the scattered medical societies of London into the great unit now known as the Royal Society of Medicine, and it is most just that we should hold his name in grateful remembrance. But MacAlister was a librarian before he became secretary to the new Society which he brought into being, and to the end of his life he was keenly interested in literature. It is perhaps not inappropriate, therefore, that I should have chosen for this lecture a subject which belongs more to the domain of letters than to that of medicine —namely, a consideration of "Praise and Dispraise of Doctors" throughout the ages. It might be thought that this is an otiose task; but I hope to be able to show that it is justified, for it is always interesting, and may be amusing, to see ourselves through the eyes of others. It is instructive also, and possibly corrective, to learn what, in the opinion of the laity, are our chief faults and what our virtues and merits.

Medical Proverbs

We may begin by glancing at the things said about doctors and their work in popular proverbs. One must not, of course, take proverbial wisdom too seriously, for it is easy to quote proverbs that are mutually contradictory, but none the less a proverb usually embodies one aspect of truth, or what the populace from its experience believes to be the truth, for otherwise it would never have obtained general currency. Now the healing art and its practitioners come home so much to the business and bosoms of men that there are naturally many medical proverbs A collection of them was published[1] some years ago and several are to be found in any dictionary of phrases, most of them, I regret to say, uncomplimentary. Here are a few examples taken from various countries :—

> He who has killed a thousand persons is half a doctor.—(*Tamil proverb.*)
>
> When you call the physician, call the judge to make your will.—(*German.*)
>
> The doctor is often more to be feared than the disease.—(*French.*)
>
> If the doctor cures the eye sees it ; if he kills, the earth hides it.—(*Scottish and Portuguese.*)
>
> God heals, and the physician hath the thanks.—(*Old proverb.*)

These, it will be observed, bring against doctors the accusation which we shall find to be very common throughout the ages: that they kill more than they cure, and that when a patient does recover it is Nature that deserves the credit. On the other hand, as showing the contradictory nature of proverbs, we have this : "A half doctor near is better than a whole one far away." More in harmony with professional views is the French and Italian saying, "A surgeon should be young ; a physician old," and it might well be considered when fixing the retiring age for medical and surgical members of a hospital staff. As a corollary to it we find : "A young physician makes a lumpy churchyard"—but as to what an old surgeon makes proverbial wisdom is silent. The most sweeping condemnation, however, is the saying in the Talmud, "The best of doctors is ripe for Hell." There is nothing half-hearted about this, and I had hoped that it really referred to doctors of the Law, but I am told by my learned friend, Dr. W. M. Feldman, that it is indeed medical doctors who are thus denounced.

The Ancient Writers

Proverbs are usually anonymous—the wisdom of many, as it has been said, embodied in the wit of one—and belong to no particular age or country ; but I turn now to the considered opinions expressed by writers of more or less eminence, mostly laymen, at different periods of history. We may begin with the Ancients, meaning by that those who wrote before the fall of the Roman Empire. Even in the earliest writings mention is to be found of the doctor and his work, but so long as the functions of the priest and the physician were more or less identical criticism was probably restrained by motives of piety or of prudence. In the Scriptures there are but few references to medicine, although we have the well-known panegyric of Jesus, the son of Sirach, in *Ecclesiasticus* : "Honour a physician with the honour due unto him. . . The skill of the physician shall lift up his head : and in the sight of great men he shall be in admiration. Then give place to the physician for the Lord hath created him," and so on. But even here one finds a sting at the end : "He that sinneth before his Maker let him fall into the hand of the physician." Then there is that poignant verse in St. Mark about the woman with an issue of blood which is as true of many patients to-day as it was 2000 years ago : "And had suffered many things of many physicians, *and had spent all that she had,* and was nothing better but rather grew worse," an oblique condemnation of our profession which might well be pondered by the gynæcologists. But it is to the classical writers of Greece and Rome that we must chiefly look for criticism, for it was only after the rise of Greek medicine that the physician began to attract much attention. Four centuries before Hippocrates, however, one finds Homer paying us a handsome compliment in the lines (I quote from Pope's translation) :—

> A wise physician skill'd our wounds to heal,
> Is more than armies to the public's weal.

Æsop (c., 570 B.C.), on the other hand, in some of his fables is decidedly disparaging, and Heraclitus (6th Century B.C.) goes so far as to say that "*if the doctors are excepted*—there is no one more stupid than the grammarian." Menander (342–290 B.C.), too, makes a shrewd hit when he exclaims, "A prattling physician is another disease to a sick man !" The same might be said with even more truth nowadays of a prattling nurse. Philemon (360–262 B.C.) brings against doctors a charge which the laity are never tired of repeating : "Doctors order for their patients a strict régime ; when they themselves are ill in bed they do everything that they have forbidden to others," and Mimnermos (7th Century B.C.) has an interesting comment on prognosis : "There are doctors who to show their worth and to be sure of an excuse make bad seem worse and of the worse make a disaster," which, it is to be feared, is true of some of us even to-day.

Plato (429–347 B.C.) has not much to say about medicine, but he speaks of "the wise physician who is worth many another man," and expresses the curious opinion that doctors "had better not be in robust health, and should have had all manner of diseases in their own persons," a dictum for the second part of which there is more to be said than for the first. In the Greek Anthology, a collection which covers nearly fifteen centuries, there are many medical epigrams, some laudatory others satirical, but their praise and dispraise mostly refers to individuals and not to the profession as a whole, so they need not be quoted here. They have been carefully studied by Dr. J. D. Rolleston.[2]

[*] The eighth annual MacAlister Lecture delivered at the National Temperance Hospital on June 21st.

[1] Brit. Med. Jour., 1911, ii., 1482.

Roman writers are more bitter in their comments than the Greeks. The reason for this no doubt was that at the time of the Early Empire most of the physicians in Rome were Greeks whom the Romans despised, and who were not only ignorant but apt to give themselves airs. Their nationality led to the whole profession being looked down upon, just as in the Middle Ages doctors were often despised because so many of them were Jews. It must be remembered, too, that a large number of the Greek physicians in Rome belonged to the slave class. The elder Pliny (A.D. 23–79), particularly, had almost as great a "down" upon doctors as Petrarch had thirteen centuries later. In his Natural History,[3] Pliny speaks of the profession as follows :—

> The art of Physicke hath this peculiar gift and priviledge alone, that whosoever professeth himselfe a Physitian, is straitwaies beleeved, say what he will and yet to speak a truth, there are no lies dearer sold or more dangerous than those which proceed out of a Physitian's mouth.
>
> There is no law or statute to punish the ignorance of blinde Physitians, though a man lost his life by them: neither was there ever any man known, who had revenge or recompence for the evill intreating or misusage under their hands. They learne their skill by indangering our lives; and to make proofe and experiments of their medicines, they care not to kill us. In a word, the Physitian only, if he murder a man, so clear he goeth away with impunity, that none so hardy as once to twit or challenge him for it: but say that one be so bold as to charge them with any untoward dealing; out they cry presently upon the poor patients, they are found fault with their unrulinesse, distemperature, wilfulnesse, and I know not what: and thus the sillie souls that be dead and gone, are shent (put upon their trial), and bear away the blame.
>
> But for these Physitians, who are the judges themselves to determine of our lives, and who many times are not long about it, but give us a quick dispatch and send us to heaven or hell; what regard is there had, what inquiry and examination is made of their quality and worthiness ?
>
> Is there any trade or occupation goeth beyond it for poisoning ? What is the cause of more gaping and laying wait after wills and testaments, than this ? What adulteries have beene committed under the colour hereof, even in Princes' and Emperors' palaces ?
>
> I mean not to say ought of their extreme avarice ; of the merchandise, spoile, and havocke that they make when they see their patients in danger of death, and drawing to their end ; nor how high they hold (as it were in open market) the easement and releafe of the sicke man's pains, whiles he is under their hands ; ne yet what pawnes and pledges they take as earnest of the bargaine, to dispatch the poore Patient out of the way at once ; and lastly, of their hidden secrets and paradoxes, which forsooth they will not divulge abroad, but for some round summe of money.

There is no reason to doubt that these strictures were deserved by many of the doctors of his day. Martial and Juvenal, also, often exercised their wit at the expense of the profession. It is unnecessary to quote from them, but I should just like to mention one of Martial's epigrams as it shows that clinical clerks were much the same in the first century as they are now :—

> I'm ill. I send for Symmachus ; he's here,
> An hundred pupils following in the rear :
> All feel my pulse, with hands as cold as snow :
> I had no fever then—I have it now.

Quintilian (A.D. 40–118) had no faith in doctors and says that medicine "serves only to keep us hopeful." He advises his readers to "put no trust in the hopes of physicians." His contemporary, Petronius Arbiter, thought, as many have done since, that a "physician is but a consoler of the mind." Plotinus (205–270) is more sweeping when he denounces medicine as "the chief of errors," whilst Flavius Valens (328–378) contents himself with the simple recommendation: "Keep the physician from your door as long as you can."

Mediaeval Criticisms

After the fall of the Roman Empire in 476 came the Dark Ages which lasted for a thousand years. It was a time during which medicine made little progress, though in justice it must be remembered that it saw the foundation of the great Medical School of Salerno and the establishment of the first rudimentary hospitals for the sick. There was an improvement in the knowledge of drugs due to the Arabians, but Roger Bacon (1214–1294) would not even admit this of the practitioners of the day, for he says [4] that "medical men are ignorant of simple medicine and at the mercy of apothecaries. In compound medicine they go entirely astray. . . They don't learn to know the drugs they use nor their prices."

The qualified "leech" of the Middle Ages was certainly not a safe doctor. His knowledge, such as it was, was derived almost entirely from Arabian commentaries on the writings of Hippocrates and Galen and he had little or no practical training. A portrait of what was probably a favourable specimen of the profession is drawn by Chaucer in his well-known description of the "Doctur of Phisik" in the "Prologue to the Canterbury Tales," the chief features in the picture being the doctor's belief in astrology, his knowledge of the classical and Arabian authors, his spare but nourishing and digestible diet, his scepticism ("his studie was but litel on the Bible"), his fine dress, and his love of money. For a balanced opinion from a cultured layman about doctors in the 12th century we may go to John of Salisbury (1118–1180):—

> The theoretical physicians do what concerns them, and for love of you will even go further. You can get from them information as to the nature and causes of particular phenomena, they are judges of health, of sickness, and of the mean state. Health, so far as words go, they provide and preserve, and as concerning the mean state they bid one incline in the direction of health. Of sickness they foresee and declare the causes, and lay down its beginning, its continuance, and its decline. What more shall I say ? When I hear them talk I fancy that they can raise the dead and are in no way inferior to either Æsculapius or Mercury.
>
> And yet with all my admiration I am much troubled at one matter, and that is they are so singularly at variance in their discussions and in the opinions which are drawn from them. For this one thing I do know, that contraries cannot both be true at the same time.
>
> Again, what shall I say about the practising physicians ? God forbid that I should say anything bad about them ! since for my sins I fall only too often into their hands. They should rather be soothed by politeness than angered by words, and I do not wish that they should treat me hardly, nor could I endure all the evils about which they

> constantly talk. I would rather say with blessed Solomon "All medicine is from the Lord, and he that is wise will not despise it."
>
> Nor is anyone more useful or more necessary than the physician so that he be faithful and full of foresight. For who can say enough in his praise who is the craftsman of health and the begetter of life in that he takes after the Lord and stands in his place, for that health which the Lord gives as a Prince, the physician, as steward and minister, administrates and dispenses.
>
> It is of little moment if some physicians sell an imaginary benefit, and that they may appear the more honest take no fee before the patient is well. But such are dishonest in that they give themselves the credit for a recovery which is due to time, or rather to the gift of God; for it is due to God and to the natural powers of his constitution that the sick man is raised up. Few are they who act in this way, for you will always hear physicians advising one another as follows:—"Take your fee while the patient still feels ill."
>
> Perhaps you look for me to say, what the common people say, that physicians are the class of people who kill other men in the most polite and courteous manner. Well, you will be disappointed; God forbid that I should do them this injury!

The *popular* opinion two centuries later was expressed succinctly by William Langland (?1330–1400) in Piers the Plowman:—

> For mortherers aren mony leches
> Lorde them amende!

whilst the view of the learned is given by Poggio Bracciolini (1380–1459), when he says flatly in his "Disputation upon the Law and Medicine": "Jurisprudence and Medicine have this in common that they are humiliating to contemplate."

The most violent mediaeval opponent of medicine, however, was Petrarch, who paid the profession the compliment of devoting four books of invectives to it. I quote from a letter to the Pope which formed the preface to the first of these books [5]:—

> I know that your sick bed is continually besieged by physicians, a fact which is my chief cause of terror, for they disagree of set purpose, and even he who can bring forth nothing new is ashamed to follow in the footsteps of another.
>
> Neither is there any doubt (as Pliny gracefully says) that they are always hunting after renown for some novelty and so traffic in our lives. Also in this art alone does it happen that a man is taken at his own valuation, and that anyone who holds himself out as a physician is at once accepted as such; but although in no form of fraud is there greater danger, yet we do not regard it, so great is the attraction of a man's own particular delusion. Besides, there is no law to punish human ignorance, no exemplary capital penalty; they learn by our danger and gain experience through our death. The physician alone can kill a man with absolute impunity.
>
> Therefore I implore you, choose one out of the many who surround you, not on account of his eloquence, but as being conspicuous for his knowledge and trustworthiness; for now, forgetful of their own profession, they have dared to come forth from their lairs and seek the grove of the poet and the rhetorician's field of action, and, not with any idea of healing, but merely to gain a dialectical advantage, they surround the beds of our unhappy sick and dispute with mighty bellowings. But my pen has carried me far beyond the limits which I had set myself, so let me here make an end, by telling you to shun the physician who is eminent not for his knowledge, but solely for his powers of speech, as you would a lurking assassin or a poisoner.

The last sentence reminds one of Osler's dictum that there are only two kinds of doctors—those who practise with their brains and those who practise with their tongues.

In another letter the Italian poet says [6]:—

> A celebrated doctor said one day in my presence: "In detracting from the art to which I am indebted for so much wealth and so many clients, I know that I lay myself open to be called ungrateful, but truth must be upheld before everything else. I believe and I frankly say and maintain that, if a hundred or a thousand people, all of the same age, of the same constitution and habits, were suddenly seized by the same illness, and one half of them were to place themselves under the care of doctors, such as they are in our time, whilst the other half intrusted themselves to Nature and to their own discretion, I have not the slightest doubt that there would be more cases of death amongst the former, and more cases of recovery among the latter." Another doctor, even more famous and learned, with whom I had one day a confidential talk, candidly and prudently answered my question why he did not abstain from the food he forbade others, by saying: "My friend, if a doctor did himself what he advises others to do or bade them do the same as he does, he would either suffer in health or in estate."

It will be evident from all this that our profession was not very popular, and probably deservedly not, throughout the Middle Age.

Renaissance Views on Medicine

With the rebirth of learning in the middle of the 15th Century there came fresh criticism of the ignorance of many doctors, and the Renaissance writers found in the profession a ready butt for their agile wit. Erasmus (1452–1536), however, as was natural in a friend of Linacre, has some complimentary things to say:—

> Antiquity rightly both believed and proclaimed that no reward worthy enough can be paid to a skilled and trustworthy doctor.
>
> The theologian makes men repent of their sins, but it is owing to the doctor that there is anyone to repent. It is vain to be a physician of souls if the soul for whom the antidote was prepared has already fled.
>
> We owe gratitude to those who drive off the enemy who flies at our throats; are we not more indebted to the doctor who fights daily for our safety against forces hostile to life?—(*Declamatio in laudem artis medicae.*)

Savonarola also is kindly, but it is well known that he had little sympathy with the Renaissance spirit:—

> The physician that bringeth love and charity to the sick, if he be good and kind and learned and skilful, none can be better than he. Love teacheth him everything, and will be the measure and rule of all the measures and rules of medicine.

There are in Montaigne's (1533–1592) Essays many references to Medicine and doctors which show on the whole his broad tolerance. I quote from Florio's translation:—

> As for me, I honour physitians, not according to the common received rule, for the necessitie sake (for to this passage another of the prophets may be alleaged who reprooved King Asa; because he had recourse unto physitians) but rather for love I beare unto themselves; having seene some, and known diverse honest men amongst them, and worthy all love and esteeme. It is not them I blame, but their arte; yet doe I not greatly condemne them for seeking to profit by our foolishnesse (for most men do so) and it is a thing common to all worldlings.—(*Of the Resemblance between Children and Fathers.*)

He repeats, however, the old gibe that doctors don't practise what they preach:—

> So do our Physitians, who, whilst they tie their patients to a strik't diet of a panada or a sirope, feed themselves upon a melone, dainty fruits, much good meat, and drinke all maner of good Wine.—(*Of Vanitie.*)

[5] John of Gaddesden: H. P. Cholmeley. Oxford, 1912.

[6] Thoughts from the Letters of Petrarch. Trans. J. Lohse, London, 1901.

To this period also belongs the delightful and often-quoted Latin epigram attributed to Euricius Cordus (f.l. 1525) which expresses what perhaps patients always think of their doctors though they do not always say it :—

> "Three faces the Phisition hath ;
> First as an Angell he,
> When he is sought ; next when he helps,
> A God he seems to be ;
> And last of all, when he has made,
> The sicke, diseased, well,
> And asks his guerdon, then he seems
> An oughly Fiend of Hell."

The following description of a fashionable surgeon of the 16th Century by William Clowes (1540–1604), himself surgeon to Queen Elizabeth and to St. Bartholomew's, is amusing, and some features of the portrait are recognisable even to-day :—

> Then riseth out of his chair, fleering and jeering, this miraculous surgeon, gloriously glittering like the man in the moon, with his bracelet about his arms, therein many precious jewels and stones of Saint Vincent his rocks, his fingers full of rings, a silver case with instruments hanging at his girdle, and a gilt *spatula* sticking in his hat, with a rose and crown fixed on the same, standing upon his comparisons, and said unto me that he could open the wound, and if it were before my face : for (said he) my business lieth not in London, but abroad in the country, and with such persons that I cannot or will not tarry for you nor for no other whatsoever. And now here he did begin to brag and boast as though all the keys of knowledge did hang at his girdle.—(*A Proved Practise for all young Chirurgeons.*)

The Elizabethan dramatists have, as was to be expected, many references to doctors in their plays, but as these have recently been collected by Mr. Macleod Yearsley [7] I need not quote any. Most of them are abusive, although Shakespeare, as Mr. Yearsley points out, usually took a more sympathetic view. Thomas Dekker (1570–1641) adopts an ambiguous attitude. In his plays he could show as much animus against the medical profession as any of his contemporaries, and yet in his Plague Pamphlets there is to be found one of the most beautiful metaphors about a doctor ever penned :—

> Make much of thy Physitian : *let not an Emperick or* Mounti-bancking Quacksalver peepe in at thy window, but set thy Gates wide open to entertaine thy learned Physitian : Honour him, make much of him. Such a Physitian is God's second, and in a duell or single fight (of this nature) will stand bravely to thee. A good Physitian comes to thee in the shape of an *Angell*, and therefore let him boldly take thee by the hand, for he has been in God's garden, gathering herbes : and soueraine rootes to cure thee ; A good Physitian deales in simples, and will be simply honest with thee in thy preservatio.

From the more serious Elizabethan writers one may select three well-known criticisms of Francis Bacon (1561–1626) in the "Advancement of Learning," all of which are more or less applicable to the present day :—

> (1) Medicine is a science which hath been (as we have said) more professed than laboured, and yet more laboured than advanced ; the labour having been, in my judgment, rather in circle than in progression. For I find much iteration, but small addition.
>
> (2) I esteem it the office of a physician not only to restore health, but to mitigate pain and dolors ; and not only when such mitigation may conduce to a fair recovery, but when it may serve to make a fair and easy passage. . . . But the physicians contrariwise do make a kind of scruple and religion to stay with the patient after the disease is deplored ; whereas in my judgement they ought both to enquire the skill, and to give the attendances, for the facilitating and assuaging of the pains and agonies of death.

(It is still difficult to persuade doctors not to strive officiously to keep alive.)

> (3) Physicians are some of them so pleasing and conformable to the humour of the patient as they press not the true cure of the disease.

Finally, it is interesting to know, on the authority of Sir Theodore Mayerne (1573–1655), that James I. himself had but a poor opinion of doctors. "The King," says Mayerne, "laughs at medicine and holds it so cheap that he declares physicians to be of very little use and hardly necessary. He asserts the art of medicine to be supported by mere conjectures and useless because uncertain."

Seventeenth Century Writers

By the seventeenth century much of the effervescence of the Renaissance had passed off, whilst the dawn of modern medicine had begun with the introduction of the experimental method by Harvey and the re-establishment of clinical observation by Sydenham. Criticism now becomes graver and more serious in accordance with the spirit of the time, whilst there is greater readiness to acknowledge the virtues of the doctor and to excuse his failings ; dispraise, however, is still commoner than praise.

Throughout the century there was a passion for the analysis of human minds and motives, and this often led to the publication of what were called "characters," composite pictures, as it were, of different types of men, although as a rule touching mostly on their passing and accidental aspects. A good example is John Earle's "Microcosmographie" (1628), which contains amongst many other "characters" one entitled "A Meere Dull Physician." It is too long to quote in full, but is entirely malevolent, and the only excuse for Earle is that he wrote it when still very young. The general tone may be gathered from one sentence : "The best cure he (the Physician) has done is upon his own purse, which from a lean sickliness he hath made lusty and in flesh." He has also a "character," styled simply and more politely "A Surgeon," of whom he says (amongst many other sarcasms) that "his gains are very ill-got, for he lives by the hurts of the common-wealth. He differs from a physician as a sore does from a disease or the sick from those that are not whole, the one distempers from within, the other blisters from without. . . . . The rareness of his custom makes him pitiless when it comes : and he holds a Patient longer than our Courts a Cause," and so on.

Thomas Fuller (1608–1661), the contemporary of Earle, is much more sympathetic in his picture of "The Good Physician" [8] of whom he says :—

> Coming to his patient he persuades him to put his trust in God, the foundation of health.
>
> He hansells not his new experiments on the bodies of his patients, letting loose mad recipes into the sick man's body. . . . .
>
> To poore people he prescribes cheap but wholesome medicine, not removing the consumption out of their bodies into their purses.
>
> He brings not news with a false spie that the coast is clear till death surprises the sick man. When he can keep life no longer in, he makes a fair and easy passage for it to go out. . . . .

And more in the same laudatory strain.

To surgeons he is equally kind.[9] "Necessary and ancient," he says, "their profession, ever since man's body was subject to enmity and casualty," and ends by "wishing unto them the three requisites for their practise, an Eagle's eye, a Ladies hand and a Lion's heart."

---

[7] Doctors in Elizabethan Drama. London, 1933.

[8] The Holy State.

[9] History of the Worthies of England. Chap. IX.

Robert Burton (1577–1640) is another classical author of the period, whose references to doctors and medicine are always in terms of praise whilst he reserves blame for those whom he terms "mountebanks, quack-salvers and empiricks."

The seventeenth century writer who was most witty and satirical at the expense of doctors was, of course, Molière, but his plays do not lend themselves well to brief quotation and are moreover very well known.

The Eighteenth Century

The eighteenth century was the age of "reason" when all established beliefs and customs were subjected to criticism from which the medical profession did not escape. Nor can it be denied that criticism was often deserved. The profession at this time was divided into three classes—physicians, surgeons, and apothecaries. Of these the physicians and surgeons were for the most part well educated and, indeed, often learned men, but their practice left much to be desired, for in spite of the progress of the seventeenth century medicine almost stood still for more than two generations, and even up to the end of the eighteenth bleeding, blistering, purging, and polypharmacy were the chief weapons in the physicians' armoury. Their manners also were open to attack, for it was an age of medical pomposity and pedantry, of full-bottomed wigs, snuff-boxes, and gold-headed canes. Voltaire's witticisms were not without point when he defined a physician as "one who pours drugs of which he knows little into a body of which he knows less," and when he said that "the art of war is like that of medicine, murderous and conjectural."

The opinions on doctors and medicine expressed by the intellectuals or "wits" of the century are much divided; some are full of contempt, others of the highest praise. Horace Walpole (1717–1797), for instance, writes: "I abhor physicians." "By quack I mean impostor not in opposition to but in common with physicians." "In physicians I believe no more than in Divines," and much more in the same strain. Lady Mary Wortley Montagu (1689–1762) is not much kinder, for she accuses doctors of opposing inoculation because small-pox brought them so much money, and speaks of "a world of filthy doses and more filthy doctors' fees." On the other hand, Pope (1688–1744), who was not over given to commendation, said of physicians that they were in general "the most amiable companions and the best friends as well as the most learned men" he knew. The highest praise, however, comes from Samuel Johnson, who counted many physicians amongst his friends:—

> Medicine is a profession which must, undoubtedly, claim the second place amongst those which are of the greatest benefit to mankind.
>
> Every man has found in physicians great liberality and dignity of sentiment, very prompt effusion of beneficence and willingness to exert a lucrative art where there is no hope of lucre.
>
> They (doctors) do more good to mankind without a prospect of reward than any profession of men whatever.

His criticisms are comparatively mild:—

> Life is not to be sacrificed either to an affectation of quick discernment or of crowded practice, but may be required, if trifled away, at the hand of the physician.
>
> How many men in a year die through the timidity of those they consult for health.

Addison is inconsistent, for in the *Spectator* he writes:—

> If . . . we look into the profession of physic, we shall find a most formidable body of men. The sight of them is enough to make a man serious, for we may lay it down as a maxim, that when a nation abounds in physicians, it grows thin of people.

But in the *Tatler* we find him (or Steele) saying:—

> There is not a more useful man in a commonwealth than a good physician . . . he uses his skill with generosity even to persons of condition, and compassion to those in want: which is the behaviour of Hippocrates, who shows as much liberality in practice, as he does wit in his conversation, and skill in his profession. A wealthy doctor, who can help a poor man, and will not, without a fee, has less sense of humanity than a poor ruffian, who kills a rich man to supply his necessities. It is something monstrous, to consider a man of liberal education tearing out the bowels of a poor family, by taking for a visit what would keep them a week. Hippocrates needs not the comparison of such extortion to set off his generosity; but I mention his generosity to add shame to such extortion.

Other eulogists are Blackstone (1723–1780) who wrote in his Commentaries: "The medical profession, beyond all others, has remarkably deserved the character of general and extensive knowledge," and Samuel Parr (1747–1825), the Whig Johnson, who thought that of the three learned professions "in erudition, in science and in habits of deep and comprehensive thinking, the pre-eminence must be assigned in some degree to physicians."

Passing to lighter comments of the century one must quote the well-known epigram which has been attributed to Samuel Garth (1661–1719), himself a physician, but also to Joseph Jekyll (1752–1837), the wit and politician, as well as to others. Of the various forms of it I prefer the following:—

> See, one physician, like a sculler, plies,
> The patient lingers and by inches dies,
> But two physicians, like a pair of oars,
> Waft him more swiftly to the Stygian shores.

Henry Fielding (1707–1754) makes a hit when he says, "Every physician almost, hath his favourite disease," and everyone will agree with Swift (1667–1745) that "no man values the best medicine if administered by a physician whose person he hates or despises."

Hannah More (1745–1833) was, perhaps, reflecting more upon patients than upon doctors when she "used to wonder why people should be so fond of the company of their physician, till she recollected that he is the only person with whom one dares to talk continually of oneself, without interruption, contradiction or censure."

Finally, we get this sly dig from James Townley (1714–1778), the author of "High Life below Stairs."

> Wonderful is the skill of a physician; for a rich man he prescribeth various admixtures and compounds, by which the patient is brought to health in many days at an expense of fifty pounds; while for a poor man for the same disease he giveth a more common name, and prescribeth a dose of oil, which worketh a cure in a single night charging fourpence therefor.

The Moderns

From the middle of the nineteenth century down to the present day the progress of medicine has been so remarkable and its benefits to the community so conspicuous that many of the old gibes at doctors have lost their point and are only repeated, if at all, in jest. Praise, therefore, amongst modern writers is found to be commoner than dispraise, and criticism is reserved more for the manners and customs of the profession as a whole than for its practice or morals. From the immense mass of modern literature one can only select a few representative opinions, and these almost entirely from writers in this country.

There is curiously little to be gleaned from the great novelists of last century. Scott gives a charming picture of a country surgeon in Gideon Gray, but except when he says that doctors are "bad guessers" he makes almost no general criticisms. Dickens has very little to say about Medicine; his strictures were reserved for the Law. Thackeray has a few references to doctors in the "Book of Snobs," which are favourable although inclined to be patronising. George Eliot, in "Middlemarch," depicted with great skill and humour different types of practitioner, but, like Scott, refrains from general praise or blame except when she says: "it is seldom a medical man has true religious views—there is too much pride of intellect."

The following passage—it can scarcely be called criticism—from Trollope's "Doctor Thorne" is amusing:—

> A physician should take his fee without letting his left hand know what his right hand was doing; it should be taken without a thought, without a look, without a move of the facial muscles; the true physician should hardly be aware that the last friendly grasp of the hand had been made more precious by the touch of gold.

Of the opinions of politicians we may take three, dating from the early nineteenth, late nineteenth, and early twentieth century respectively.

> Lord John Russell (1792–1878): I admire the habits of a physician; he sees the weakness of our nature; he is generally just and conscientious, though somewhat selfish; from the contempt which his profession must give him of mankind, his mind is rather accurate than exalted.
>
> Lord Salisbury (1830–1903): Doctors are a social cement.
>
> Mr. Lloyd George: While I was dealing with the Insurance Act I had much to do with doctors. I found them unreasonable and unruly.
>
> The doctors are always changing their opinions. They always have some new fad.

Ruskin's tribute to the profession in the "Crown of Wild Olives" is well known:—

> So of doctors. They like fees, no doubt—ought to like them; yet if they are brave and well-educated, the entire object of their lives is not fees. They, on the whole, desire to cure the sick; and—if they are good doctors, and the choice were fairly put to them—would rather cure their patient and lose their fee, than kill him and get it.

And here is a selection of *obiter dicta* by various writers arranged roughly in chronological order:—

> He is the best physician who is the best inspirer of Hope.—*S. T. Coleridge* (1772–1834).
>
> A physician ought to be extremely watchful against covetousness; for it is a vice imputed, justly or unjustly, to his Profession.—*Thomas Gisborne* (1758–1846).
>
> The sixth commandment is suspended by one medical diploma from the North of England to the South.—*Sydney Smith* (1771–1845).
>
> Doctors are generally dull dogs.—*John Wilson* ("Christopher North") (1785–1854).
>
> This is where the strength of the physician lies be he a quack, a homœopath or an allopath. He supplies the perennial demand for comfort, the craving for sympathy that every human sufferer feels.—*Tolstoy* (1828–1910).
>
> A physician's physiology has much the same relation to his power of healing as a cleric's divinity has to his power of influencing conduct.—*Samuel Butler* (1835–1902).
>
> Doctors are the only autocrats we have left.—*E. F. Benson*.
>
> No one appreciates the medical profession more highly than myself. Doctors are the most generous of men; but they are unwise when they represent doctoring either as an art or a science. The late Dr. Jowett once said that logic "was neither a science nor an art, but a dodge," and doctors would be better appreciated if they would frankly admit that doctoring is like logic.—*Anonymous Author of More from a Lawyer's Notebook*. 1933.
>
> On the whole the doctors I have known have been amongst the finest men of my acquaintance. I have found them the kindest and wisest friends . . . . their generosity far surpasses what I have found in any other profession.—*Dean Inge.*

I should like to quote Mr. Kipling's very eloquent praise of the medical profession in the Address which he gave some years ago at the Middlesex Hospital but time does not permit, so I shall conclude these excerpts with Robert Louis Stevenson's charming Dedication in "Underwoods."

> There are men and classes of men that stand above the common herd: the soldier, the sailor, and the shepherd not unfrequently; the artist rarely; rarelier still, the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilisation; and when that stage of man is done with, and only remembered to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race. Generosity he has, such as is possible to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarrassments; and what are more important Heraclean cheerfulness and courage. So it is that he brings air and cheer into the sick-room, and often enough, though not as often as he wishes, brings healing.

The Conclusion of the Whole Matter

Glancing back over the ground which we have now traversed we shall be convinced, I think, of the truth of the saying of an American writer, Charles L. Dana, that "all the real, solid, elemental jests against doctors were uttered some one or two thousand years ago." For medical satire and dispraise throughout the ages have always been much of the same kind. We are accused of ignorance, of greed for money, and of not practising what we preach; on the other hand, we are praised by other writers for our learning, and for our liberality and generosity. It would appear that praise and dispraise pretty well cancel out, just as in the individual practice of each of us undeserved blame is balanced by unearned credit. We have seen that in the earlier periods of medicine blame was probably often well merited but that as the profession has risen in efficiency so it has gained in esteem. Even now, however, it is probably true to say that the individual doctor is better liked than the profession as a whole; and contemporary criticism is directed more against our so-called "medical etiquette" and our attitude towards the irregular practitioners outside our ranks than against our personal failings. Meanwhile, a survey of the praise and dispraise of which we have been the subject throughout the ages is worth while if it helps us, both as individuals and as a profession, to be ever more worthy of the one and undeserving of the other.

Note.—The quotations in this lecture are chosen from a much larger number, collected by Dr. Gladys Wauchope and myself, which are being published in the London Hospital Gazette as a "Medical Anthology."

INFANTILE DIARRHŒA
WITH SPECIAL REFERENCE TO DEHYDRATION AND OTITIS MEDIA

By Montague Maizels, M.D., M.R.C.P. Lond.
CLINICAL PATHOLOGIST, UNIVERSITY COLLEGE HOSPITAL; LATE PATHOLOGIST, INFANTS HOSPITAL, WESTMINSTER; AND

Jean Smith, M.D., M.R.C.P. Lond.
ASSISTANT PHYSICIAN TO THE INFANTS HOSPITAL AND THE PRINCESS LOUISE HOSPITAL FOR CHILDREN

Infantile diarrhœa is among the most interesting of maladies, presenting problems for elucidation in preventive medicine, pathology, and physiology.

When acute diarrhœa occurs in previously healthy infants it tends to be somewhat self-limited. At the onset it may be of slight or choleraic intensity, but if the initial symptoms are survived there is a good chance of recovery, although relapse may follow. When, however, it occurs in a child previously undernourished or marasmic, the outlook is not nearly so good. The onset may be mild, but the illness develops with a certain momentum; improvement is often followed by relapse and one or more of these is likely to prove fatal.

It is seldom that a specific organism can be isolated, though infections due to dysentery bacilli (Flexner or Sonne) have been described. Nor are the post-mortem findings characteristic. In fatal cases the following appearances may be noted: Dehydration and wasting are extreme. The gut is inflamed but the degree of redness is not proportional to the severity of the symptoms, in so far as slight hyperæmia may sometimes be associated with severe diarrhœa; the lower ileum is usually involved; next in frequency is the colon and the stomach; then the duodenum and least often the jejunum. The erythema is patchy; sometimes the Peyer's patches and solitary follicles are specially affected, but often they are not. There may be submucous hæmorrhages, but definite ulceration is not common. Inflammation of the mesenteric glands is frequent, but in some cases, more especially in marasmic infants, the lymphoid tissues appear to be atrophic. The liver and kidneys are often fatty and sometimes markedly so. The lungs frequently show hypostatic congestion or broncho-pneumonia. The heart is usually dilated and the muscle pale. The pia-arachnoid may show œdema and the grey matter of the brain is often hyperæmic and looks pink. In 60 per cent. of autopsies pus-like material was found in the middle ears or mastoids, and occasionally in the nasal air sinuses (once in five cases examined).

BIOCHEMICAL CHANGES

The biochemical changes in infantile diarrhœa are very complex and depend primarily on starvation, loss of fluid, loss of salts, and toxæmia. In mild cases these changes may be slight, but if diarrhœa is severe, divergences from the normal are always considerable. The following observations are based on 243 examinations of 168 severe cases carried out in collaboration with Miss C. B. McArthur at the Infants Hospital; an analysis of 48 of these cases has been published elsewhere.[1]

Starvation.—In the diarrhœa of infants the starvation factor is well marked, but ketosis is not common and was absent in some of the worst cases; in 16 per cent. traces of acetone were found in the urine; in 13 per cent. much acetone was found, and in 3 per cent. diacetic acid as well as acetone.

Dehydration.—The influence of dehydration is more important. The variation in fluid content may be demonstrated by daily weighing or by hæmoglobin estimations. Thus an early case with 70 per cent. of hæmoglobin may show a rise to 90 per cent. in 24 hours, to be followed by a decrease to 80 per cent. or less as a result of treatment, and then again another rise to 100 per cent. as a result of continued diarrhœa. Such hydrolability is very characteristic of infantile diarrhœa. This loss of fluid greatly diminishes the blood volume and increases its viscosity, so that the peripheral circulation becomes small and sluggish. For this reason the extremities are blue and cold. Tissue oxidation becomes imperfect, so that lactic acid and other more complex acids are produced and these result in acidosis.[2]

The general deficiency in blood-supply is shared by the kidneys, which themselves may be further damaged by toxæmia. Water, urea, phosphate, and chloride are not freely excreted, and the retained urea may be very high; it was above 0·1 per cent. in 19 observations on 28 severe cases. The phosphoric acid retained as a result of renal insufficiency contributes to the acidosis.[3] Further, both acids and bases are lost in the frequent, loose stools, but as there is usually an excess of base excreted by the gut, there remains in the blood an excess of acid over base.[4] This is a further cause of acidosis.[5] In 9 per cent. of our 168 cases the alkali reserve of the blood was less than one-half (and in five cases less than one-fifth) of the normal. Moderate acidosis was present in 42 per cent. of the cases; in 33 per cent. the plasma bicarbonate was normal (22–28 millimoles) or nearly normal; 16 per cent. showed an alkalosis, including 6 cases where the alkali reserve was approximately doubled. Alkalosis has usually resulted from alkali therapy but in three instances appeared to be primary. The loss of salts in the stools, and of chloride in particular, is sometimes so great as to lead to a deficiency of chlorides in the blood (29 per cent. of our cases), but more often the accompanying loss of water is so much more marked and the blood in circulation so diminished in volume as to lead to an actual increase in the chloride content (33 per cent. of cases). It follows that the greater the dehydration, the greater the plasma chloride and the less the alkali reserve. There is thus a reciprocity between plasma bicarbonate and chloride, so that, generally speaking, they vary inversely (Table I.).

Table I.—*Plasma Bicarbonate and Chloride*

Alkali reserve (millimoles).	Plasma chloride.		
	Increased per cent.	Normal 95–105 mm.	Decreased per cent.
–10	75	19	6
10–20	50	44	6
20–30	25	39	36
30 and over ..	12	38	50

The abnormal acids circulating in the blood are excreted by the kidneys and hence the urine becomes excessively acid. These acids in the normal urine are combined partly with fixed bases, sodium, potassium, calcium, and magnesium, and partly with ammonia. This ammonia is formed by the kidneys as required. In the acidosis of diarrhœa, the fixed bases are retained to neutralise the acids in the tissues, and the acids of the urine are combined with ammonia. If the kidneys are relatively healthy, they are able to supply all the requisite ammonia, and the ammonia coefficient of the urine rises considerably. If, however, the kidneys are damaged by the general disorder, ammonia formation fails; a urine of intense acidity is excreted and the ammonia coefficient is not raised.

It would obviously be of value if one could determine the presence or absence of acidosis from the urine alone without tedious blood examinations. This, however, is not possible, for the reaction of the urine is often acid when the blood is normal, and even when the blood is excessively alkaline. Again, if the kidneys are failing, acidosis is not accompanied by a raised ammonia coefficient; on the other hand, the ammonia coefficient, although often raised in the presence of acidosis, may be quite high when the alkali reserve is normal or increased. It is certainly true to say that an alkaline urine never occurs with acidosis, but this sign is of little value, since alkaline urines are rare in any stage of diarrhœa (Table II.).

TABLE II.—*Plasma HCO_3 and Urine (pH, &c.).*

—	Acid urine (pH 6·2 and less).	NH_3 coefficient to—		
		−8 per cent.	8–12 per cent.	12 per cent. and over.
	Per cent.			
Marked acidosis	100	14	29	57
Moderate acidosis	84	14	29	57
Normal	78	32	26	42
Alkalosis ..	60	45	25	30

Similarly with regard to the urinary chloride: if chloride is present in the urine, blood chloride may be high or normal; it is probably not low. On the other hand, absence of chloride from the urine tells us nothing about the chloride concentration of the blood, which may be low or normal; or if the kidneys are so damaged as to fail in the excretion of chloride, the urine may be chloride-free while there is a considerable accumulation of chloride in the blood (Table III.).

TABLE III.—*Plasma and Urine Chloride*

	Urine chloride less than 0·08 per cent.
Plasma chloride less than 95 mm. ..	89 per cent.
Plasma chloride 95–105 mm. ..	57 ,, ,,
Plasma chloride over 105 mm. ..	45 ,, ,,

Blood and Cerebro-spinal Fluid Chloride.—The relation between the plasma and cerebro-spinal fluid chloride is closer, the latter running parallel with but higher than the former. For this reason the cerebro-spinal fluid chloride is sometimes increased by 50 per cent. in renal retention cases, while in the rarer examples of chloride depletion, cerebro-spinal fluid chloride readings of 90 millimoles (0·52 per cent. NaCl) and less may be encountered. Most of our cerebro-spinal fluids were obtained *post mortem*, but the findings were confirmed by estimations made on five fluids obtained during life for suspected meningitis.

SIGNIFICANCE OF BLOOD CHANGES

It may be said that the following chemical findings have a bad prognostic significance: (1) acidosis with a low ammonia coefficient; (2) alkalosis with an acid urine. The degree of acidosis alone is no guide to the severity of a case, for patients with marked acidosis may recover and others with a normal alkali reserve succumb. In fact, blood examinations tell us little prognostically beyond what can be directly observed from the patient's dehydration and other clinical signs. The chemical findings have, nevertheless, a very definite bearing on the type of extra fluid which should be given therapeutically to make good water and mineral loss. One result of biochemical investigations has been to show that normal saline is an unsuitable fluid to administer to dehydrated infants (Hartman[6]) and is on the whole contra-indicated in cases of infantile diarrhœa.

The sum of chloride plus bicarbonate in the blood is set at a fairly constant level (about ⅛ molar) and they are complementary in the sense that if the amount of one increases the other decreases in order to keep the sum of HCO_3 plus Cl constant. Thus, if we inject a strong solution of saline into an infant we raise the blood chloride from the normal 0·6 per cent., and in order to bring the HCO_3—plus—Cl back to normal as quickly as possible the kidneys excrete not only chloride but also bicarbonate. Hence the injection of salines leads to a complementary elimination of the alkali reserve and thus to an acidosis.

If, as is often the case, low plasma bicarbonate, high chloride, and dehydration exist before treatment, chloride injection increases the acidosis and blood chloride still further. It may also increase the dehydration. Thus if 150 c.cm. of 0·9 per cent. saline are injected, the blood chloride will rise. If the kidneys are not functioning well the patient may become œdematous; if renal function is good the kidneys endeavour to excrete the great excess of chloride in the blood. It is a matter of experience that the chloride in the urine is not likely to exceed a concentration of 0·45 per cent.; hence, in order to eliminate the excess of sodium chloride in the 0·9 per cent. saline injected, at a concentration of 0·45 per cent. or less in the urine, much of the extra fluid is wasted, and if copious saline injections are given in the course of a day, the patient may actually sustain a net loss of fluid in the exchange.

This sequence of events is denied by Hoag and Marples,[7] who find that injections of normal saline neither raise blood chloride nor increase acidosis. It must be noted, however, that their saline infusions were supplemented with copious intravenous injections of glucose. Routine intravenous therapy of this kind complicates treatment and, in its absence, it seems likely that acidosis may still be expected. Few of our cases received normal saline, but our experience agrees with Hartmann. Thus in one patient so treated the blood chloride doubled in a few hours and a condition of general œdema with symptoms of cerebral irritation developed. Later, however, the œdema disappeared and the child relapsed into a condition of profound dehydration.

As an alternative to 0·9 per cent. saline, half-strength saline may be used and is to be preferred. Glucose has certain advantages, because the glucose can be completely oxidised in the body and does not require to be excreted by the kidneys; the whole of the water therefore in which it is dissolved can be entirely devoted to the relief of dehydration. Hoag and Marples rightly insist on the importance of maintaining a free secretion of urine, and for this reason we feel that it is wisest to combine glucose (2½ or 5 per cent.) with hypotonic saline (0·45 per cent.). The fluid so added to the body improves the peripheral and renal circulation and so helps to remove acidosis. But if the acidosis is severe, glucose alone will not act promptly enough and sodium bicarbonate must be given as well. The risk of overdosage with alkali is slight; it may be suspected if the breathing becomes shallow, but can only be demonstrated with certainty by blood examination. Sometimes overdosage with alkali is accompanied by the excretion of an alkaline urine, and this is a favourable sign; in bad cases, however, a marked and dangerous excess of alkali may exist in the blood, which the kidneys, being damaged, fail to excrete and hence the urine remains strongly acid.

To avoid the risk of alkalosis, and also the execution of tedius blood examinations, Hartmann of St. Louis has introduced a buffered lactate solution.[8] It consists of a weak solution of sodium lactate and saline. The solution itself is neutral and does not tend to disturb the reaction of the blood while, if acidosis be present, the lactate is converted into bicarbonate and is available for neutralisation. If, on the other hand, acidosis is absent, the conversion of lactate into bicarbonate is so slow as to render the risk of alkalosis very slight.

TREATMENT

In spite of all that has been written in recent years on the treatment of infantile diarrhœa, prophylactic measures still remain the chief weapon in reducing the mortality from this disease. Breast feeding is the great safeguard. The consensus of opinion seems to favour moderate purgation and starvation in early cases only, but to avoid these procedures in cases of longer standing. It is usually conceded that fat and carbohydrates are not well tolerated. In three cases of the present series it was thought that skimmed breast milk was valuable.

Of the several symptoms associated with diarrhœa and vomiting it is possible to discuss here only three: dehydration, ketosis, and otitis media.

Dehydration.—The alleviation of this condition is of paramount importance. There is a choice of routes, and fluid may be given orally, subcutaneously, intraperitoneally, or intravenously in this order, until the dehydration is relieved. Oral administration alone is seldom successful in cases of any severity: the intestinal capillaries are collapsed and absorption from the gut becomes uncertain and erratic. If absorption does not occur, glucose and saline given by mouth add to the fluidity of the bowel contents and increase diarrhœa. A suitable fluid for oral administration is sodium bicarbonate, ½–1 per cent., with glucose, 5 per cent.

If dehydration is severe, fluid may be given subcutaneously or by the intraperitoneal or intravenous route. For all-round utility, subcutaneous injections are suitable. Glucose, 5 per cent. with 0·45 per cent. saline, may be used. The sugar must be pure and is best sterilised as a dry powder and added to warm sterile water. Failing this, 0·45 per cent. saline may be given. Sodium bicarbonate is valuable, but its sterilisation is a complicated procedure. It is not suitable for general use. Hartmann's buffer lactate solution is very useful in severe cases, when it is safe to assume that acidosis is present. Several ounces may be given at a time, and it may be repeated several times a day.

The great advantage of intraperitoneal injection is that five or more ounces may be given at a time. Sodium bicarbonate and glucose are not suitable for intraperitoneal injection, and although 0·45 per cent. saline may be given, the buffer solution recommended by Hartmann has certain advantages. While it is customary for the nursing staff to give subcutaneous saline, intraperitoneal injections must necessarily be given by one of the medical staff, and therefore are not as easily arranged.

Intravenous therapy should be employed in all urgent cases; 10 c.cm. of fluid per pound body-weight is a proper amount, and 7·5 per cent. glucose may be used or, if acidosis is present, Hartmann's buffer solution. If available, a sterile solution of glucose, 5 per cent., and sodium bicarbonate, ½–1 per cent., is valuable in cases with severe acidosis. Intravenous injections may be given by the method described by Marriott.[8] A brachial vein is safest but least easy of access; the external jugular is more easily entered and, if neither of these is available, then the superior longitudinal sinus may be used. Sometimes the temporal or external saphenous veins are found suitable.

In America blood transfusion has been widely used, but at the Infants Hospital the results of this form of treatment have not been good. Of 20 very severe cases 3 were greatly improved, but the others were not benefited. Perhaps if small repeated transfusions were given earlier in the disease better results might be obtained; 10 c.cm. per pound body-weight was usually given and by the same routes as mentioned for intravenous salines.

There is no doubt that the parenteral injection of fluid is very valuable. A few patients seem shocked by the procedure, but the majority appear to suffer little discomfort. For routine use, subcutaneous or intraperitoneal injections are most useful and sometimes the results are strikingly good. Frequently the ultimate result does not fulfil the promise of early treatment. The continuation of the diarrhœa may necessitate repeated injections which fail to keep pace with the loss of fluid; dehydration recurs and death is not long delayed. It sometimes happens that an infant is sustained for weeks by fluid administered in this way. In our experience, however, although subcutaneous injections will often prolong life in desperate cases for three or four days and thus give the infant's powers a chance to overcome the infection after this period we have shot our bolt and little can be expected from further injections. Nevertheless a definite number of infants are saved in this way who otherwise would be lost.

Ketosis in Infantile Diarrhœa.—While acidosis is common in this disease, ketosis is rare; sometimes, however, much acetone and diacetic acid are found in the urine. In such cases, if the symptoms are severe, glucose and small doses of insulin are useful, but owing to the risk of hypoglycæmia no case should be treated in this way outside a hospital, where it can be under constant close supervision and the treatment can be regulated by blood examination. In cases without ketosis, insulin is not helpful.

OTITIS IN INFANTILE DIARRHŒA

We carried out examinations of the middle ears at the Infants Hospital during 1931 and the early months of 1932. The object was to arrive at some definite conclusion with regard to the significance of otitis media and the part it played in the ætiology of infantile diarrhœa and the form of treatment which should be adopted. All the cases of diarrhœa and vomiting were in-patients at the Infants Hospital during the period mentioned and all but two were under the age of nine months. In every instance there was considerable dehydration with loose, frequent stools.

Altogether there were 72 cases of diarrhœa and vomiting, of which 37 (51 per cent.) recovered. In a preceding investigation routine examination of the ears during life was not made, but post-mortem examinations showed that pus-like material was present in the middle ears in 41 of 68 fatal cases. This contrasts with the findings in other diseases where pus was found in 10 of 33 autopsies. The term pus is used throughout this paper to mean thick creamy yellow or green fluid, and not merely a turbid fluid such as is often present in the ears of infants. Since routine examination of the ears has been adopted 72 cases of diarrhœa and vomiting have been followed.

In all cases in which otitis media occurred a correct diagnosis was made, except in one case which was considered to have been normal during life but which was shown to have pus post mortem.

Facies.—While it is common knowledge that otitis media during the last six months of the first year of life is associated with pulling or rubbing the ears, rolling the head, flushed cheeks, restlessness, and crying, it is not generally recognised that in the early months it may be present without these symptoms in a listless, apathetic, pale, toxic-looking child. The grave condition of the child who lies in a somnolent state—with, perhaps, head retraction—may suggest a diagnosis of intracranial trouble. A rise of temperature of varying extent was present in all our cases. In the majority the maximum temperature was between 100° and 103°, the marasmic infants tending to the lower temperatures.

Ears.—In examining the ears in small children an electric auroscope is almost essential. In any case of diarrhœa and vomiting the following appearances of the ears may be found :—

1. *The drum may look normal.*—The normal infant's drum is pearly grey and translucent, although the light reflex is not as bright as it is in adults. It may be difficult or even impossible to see the drums in some infants, because they may be placed too obliquely, or the meatus may be too small, or the lumen may be blocked by debris or numerous fine hairs.

2. *The drum may be pinker than normal.*—Before the drum can be considered pathologically hyperæmic it is necessary to exclude such causes of temporary hyperæmia as recent cleaning or syringing the meatus, or even crying. Provided that such causes can be excluded, it may be assumed that a hyperæmic drum results from infection of the middle ear. If the drum is only faintly pinker than normal, preserves its translucency, and is not bulging, the condition is only catarrhal, and will probably subside without myringotomy. If, however, the drum is pink and no longer translucent or if it is definitely red, pus is probably present. If in addition the drum is not only red but bulging, the presence of pus may be assumed with confidence (Case 1). The amount of pus which is present in these cases varies considerably. Where the drum is bulging, pus usually wells up immediately the incision is made; in others only a bead of pus escapes, and in still others none at all. In such cases as these last it has been found that gentle aspiration may reveal pus which would otherwise escape observation. In our experience this may best be accomplished by attaching a rubber bulb to the side opening of the electric auroscope and exerting gentle suction with the bulb (Case 2).

3. *The drum may be pale.*—In certain cases no hyperæmia of the drum was noticed at any time, the drum on first inspection presenting a greyish-white, opaque appearance with a diminished or absent light reflex. In some instances dilated vessels were observed coursing over the drum in leash-like fashion from the posterior superior wall of the meatus (Case 5). It was especially in such cases that the presence of pus was not revealed until suction was applied.

4. *Meatus.*—In certain cases the posterior superior meatal wall was red and swollen, and sometimes sagged into the lumen of the meatus (Cases 2, 3, and 4). Although in most instances these changes were accompanied by changes in the drum, in a few no such tympanic changes were present. These meatal changes are, of course, well known, and it seems probable that they are the result of disease in the mastoid antrum. Occasionally sagging of the meatal wall was so marked as completely to obscure the drum. In no instance was any post-auricular redness or œdema noticed.

The detailed findings are as follows: in 37 cases examined aural infection was bilateral in 25 and unilateral in 12. The drums were red in 29 cases and in 9 of these bulging was observed. The posterior superior meatal wall was red and swollen in 15 instances. In 11 of these the drum was red, in 2 it was white and opaque, and in 2 it appeared normal. Opaque white drums were seen on 6 occasions.

The Blood Count.—With the occurrence of otitis media an increase of the polymorphonuclear cells was usually noted. Leucocytosis, however, has no positive diagnostic value, although its absence suggests that aural infection is unlikely :—

	Otitis (21 cases).	No otitis (17 cases).
Polymorphonuclears— 60 per cent. or over ..	13 (62%) ..	6 (35%)
Total leucocytes— 13,000 or over per c.mm.	18 (85%) ..	7 (41%)
Polymorphonuclears— 8000 or over	18 (85%) ..	5 (29%)

Treatment.—In view of the unsatisfactory results of untreated otitis media, some of the later cases received local treatment. Of 17 untreated cases 3 recovered, 2 having drained and 1 having resolved spontaneously; mortality, 80 per cent. Of 20 treated cases 10 recovered; all had paracentesis and 5 had antrotomy (bilateral in two instances); 10 died: all had paracentesis and 5 had antral drainage (1 bilateral); mortality, 50 per cent. In 35 cases without otitis the mortality was 31 per cent.

CASE-HISTORIES

CASE 1.—Five months. Admitted March 4th, 1931. Diarrhœa and vomiting three days. Temp. 103° F. March 6th: Right drum red and bulging; left drum red but not bulging. Paracentesis both drums; pus welled up from the right but not from the left. March 13th: Right ear still discharging but less than during the last three days. Left ear dry. Child made uninterrupted recovery.

CASE 2.—Two months. Admitted June 10th, 1931. Temp. 101° F. Severe diarrhœa and vomiting. Both drums pink. June 15th: Temperature fallen to normal but child looking very ill. Diarrhœa and vomiting unaltered. Both meati red and œdematous; drums cream-coloured, sodden, and opaque. Drums incised but no pus escaped until suction applied with Seigel's speculum. Pus then welled up. June 17th: Ears discharging freely. Diarrhœa and vomiting stopped, and general condition much improved. June 24th: Right ear clean and dry but abscess pointing through left superior meatal wall. Abscess opened and drained. Child's general condition not as good as week ago. June 30th: Both drums pale and sodden. Child much worse. Paracentesis yielded pus both sides. Double antrotomy under local anæsthesia revealed both mastoids full of pus. Child died 12 hours later.

CASE 3.—Ten weeks. Admitted Oct. 13th, 1931. Diarrhœa and vomiting five days. Loose, frequent, green stools with severe dehydration. Oct. 15th: Drums normal but both meati red and œdematous. Oct. 16th: Drums pale and opaque, upper part of drum and superior meatal walls more œdematous than on 15th. Both mastoids opened under local anæsthesia. Pus present on both sides. Cultures yielded a pure growth of *pneumococci.* Blood transfusion of 60 c.cm. given at same time as operation. Oct. 17th: Child much improved. Temperature falling, no vomiting. Oct. 18th: Further improvement. Child made excellent recovery. No vomiting and stools rapidly became normal after operation.

CASE 4.—Twelve months. Admitted May 12th, 1931. Otorrhœa left ear and adenitis. Vomiting and loose stools. Temp. 104·8° F. May 15th: Perforation right drum. Very little discharge. Superior meatal walls very œdematous. Profuse discharge from left ear. May 18th: Right ear shows a large bullous swelling with dilated vessels on its surface projecting from the superior meatal wall. Swelling completely obscures the drum. On making an incision into this swelling a large amount of pus escaped. May 20th: Right ear discharging freely. Child much better. June 2nd: Child quite well. Right drum normal, and only slight trace of incision on meatal wall.

CASE 5.—Eight months. Admitted June 8th, 1931. Diarrhœa and vomiting three days. Temp. 103° F. Drums normal. June 10th: Drums pale with leash of dilated vessels spreading from superior meatal walls on to drums. Paracentesis: no pus obtained. Child died four days later. Post mortem: both mastoids full of pus.

DISCUSSION

The association of diarrhœa with otitis has long been known and the frequent finding of pus-like material in the ears post mortem was demonstrated by Renaud.[9] While a few of these fluid collections are due to post-mortem degeneration (Alexander[10]) the presence of pus cells and hæmolytic streptococci indicates that the majority are ante-mortem.

The sequence of events in combined intestinal and aural infection has led to much divergence of opinion, although it is agreed that the frequency of otitis may be explained by the disposition of the Eustachian tube, which in infancy is relatively short and straight. Marriott[11] and Jeans and Floyd[12] have thought that a streptococcal otitis or mastoiditis is often, though not always, primary. Marriott states that the drum usually showed changes and that there was a consistent sagging of the posterior superior meatal wall near the drum. As the aditus is too small in infants to permit drainage from the antrum through the middle ear, double antrotomy was carried out, and Marriott reports that the procedure gave almost immediate relief of symptoms in a large proportion of cases. Wishart[13] and Maybaum,[14] on the other hand, are of the opinion that otitis and mastoiditis are secondary events. They point out that aural infections are rarely present when patients are first admitted to hospital but develop during their stay in the ward, and are not infrequently agonal events which take place during the last day or so of life and have no real influence on the course of the intestinal intoxication. Maybaum advocates local treatment, but only in the presence of definite local indications.

We are of opinion that the significance of otitis varies in different patients. In three cases otitis preceded enteritis, and in these paracentesis gave good results. In a little more than half of the cases signs of aural infection were present soon after the diarrhœa and vomiting began and were observed within four days of the patients' admission to hospital. The remaining instances of aural infection were late, and sometimes signs were only noticed for the first time when death was imminent.

It seems clear that otitis is rarely the primary cause of intestinal intoxication. On the other hand, once secondary otitis or mastoiditis has occurred a new obstacle to recovery has arisen, and one may well doubt if resolution of the intestinal lesion is possible in the absence of free aural drainage. We consider that if the drums are red and bulging they should be incised. If the drums are red but not bulging and the patient is not very ill, incision may be delayed, but if further deterioration occurs paracentesis should be carried out. Often a bead of pus escapes but sometimes puncture is negative. In some of the latter cases pus may well up after the application of suction through a speculum.

If signs are negative the ears should be left alone. While myringotomy is not a severe operation, the question of antrotomy is more anxious. Marriott and many others state that double antrotomy gives rise to very little shock. We agree that the degree of shock is much less than might have been expected, and that antrotomy should be carried out provided that there is definite œdema and redness of the posterior superior meatal wall. Our small series of cases suggests that adequate aural drainage definitely reduces mortality and possibly better results might have been obtained with earlier operative treatment.

Coates[15] and others express the view that if myringotomy fails to relieve the general symptoms, then this in itself is an indication for double antrotomy. Findlay[16] on the other hand finds the results of aural treatment very disappointing. One must remember, however, that the mortality in severe diarrhœa is high, even when the condition of the ears is unimpeachable; and hence when aural complications are present myringotomy or antrotomy must often be followed by failure.

In conclusion it is necessary to bear in mind that the mortality in infants with enteritis of moderate and marked severity is over 50 per cent., and at present no line of treatment gives consistently good results. Much research of a biochemical and bacteriological nature remains to be done on the management of the developed case, but one will always have to depend chiefly on preventive measures to lower the mortality from infantile diarrhœa.

Our thanks are due to the medical and surgical staff of the Infants Hospital for permission to publish these observations on their cases.

THE BLOOD SEDIMENTATION RATE AND THE PLASMA PROTEINS

By G. R. P. ALDRED-BROWN, B.M. Oxon.
PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH: AND

J. M. H. MUNRO, D.Sc., L.R.C.P. Lond., F.I.C.
PATHOLOGIST TO THE HOSPITAL

FAHRAEUS in 1918 reawakened interest in the difference between the behaviour of shed blood in health and certain morbid conditions.[1] He pointed out that the rate of fall of the red blood corpuscles after the addition of an anticoagulatant (which rate of fall is termed now the sedimentation rate) was accelerated in pregnancy and various pathological states. The nature of the reaction has remained to this day a problem and numerous explanations have been put forward to account for it.

There are certain factors in this connexion on which it may be said that nearly all observers are agreed: firstly that the red corpuscles aggregate into clumps, thus increasing the size of the sedimenting particles; secondly that the force or forces which cause the corpuscles to aggregate are inherent to the plasma and not to the corpuscles themselves; and thirdly that the number of corpuscles influences the rate, the latter being increased when the corpuscles are reduced.

Amongst the theories that have been advanced has been (1) that the agglutination of the red corpuscles is caused by an absorption phenomenon resulting from the lowered electrical burden of the suspended particles, and thus the sedimentation rate depends on alterations in height of the electrical burden of the particles; (2) that it is controlled by the viscosity of the blood; and (3) that sedimentation depends on the composition of the plasma proteins. Some observers believe that it is the fibrinogen in the plasma that regulates the rate of sedimentation; others believe it to be the plasma globulin, and still others maintain the all-important factor to be the fibrinogen-globulin-albumin ratio, the fibrinogen and globulin tending to increase the sedimentation rate and the latter to decrease it. Some hold that it is possible for all these three theories to be correct. However, there can be little doubt that the theory that the composition of the plasma proteins determines the sedimentation rate is the most widely held one and is the one that appears in modern text-books (e.g., Beaumont and Dodds[2]).

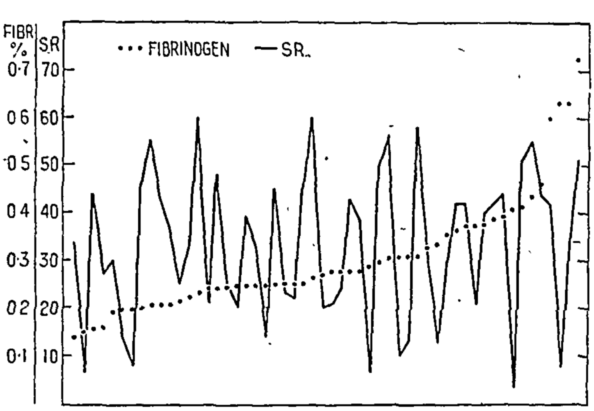

FIG. 1.—The percentages of fibrinogen in the blood plasma of 54 patients are arranged in ascending order of magnitude (black dots). The sedimentation rates of the same patients, when joined by a black line, show no general upward trend to correspond with the upward trend of the black dots. This shows that there is no relation between fibrinogen percentage and the rate of sedimentation.

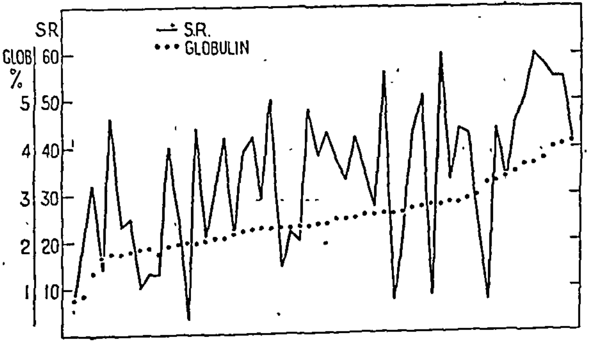

FIG. 2.—Here the black dots represent the percentages of globulin arranged in ascending order. Again the corresponding sedimentation rates show no significant upward tendency.

We undertook the present investigation in order to throw light on a subject in which, we believe, theory rests on an insecure foundation of experimental evidence. Our investigations lead us to conclude that the sedimentation rate has *no* connexion whatsoever with the fibrinogen, globulin, or albumin of the plasma.

Gram[3] in 1921 estimated the fibrin content of the blood in normal and pathological conditions and found that the sedimentation rate depended on the fibrinogen percentage of the plasma, the sedimentation being accelerated by a rise in the value and vice versa. This method of estimating the fibrinogen, Gram described at a later date (1929)[4] as "primitive."

Fahraeus[5] made solutions of the different protein fractions of the plasma prepared by precipitation with ammonium and magnesium sulphate, and to these solutions added corpuscles obtained by centrifuging and washing with saline. He found that the red corpuscles behaved differently in the various solutions. When suspended in a pure fibrinogen solution, they aggregated and settled with marked rapidity. When suspended in a pure serum globulin solution, aggregation and sinking were not so pronounced, but still very marked. When suspended in a pure solution of serum albumin, on the other hand, the red corpuscles did not aggregate and sedimentation was very slow.

It is doubtful, however, whether this experiment proves that this is what occurs in shed blood, since, as pointed out by Race,[6] centrifuging and washing with saline alters the shape of the corpuscles, and may also result in the adsorption of sufficient electrolytes to impart a positive charge to the corpuscles.

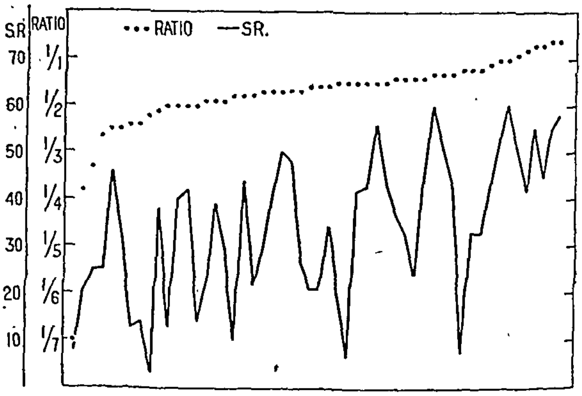

FIG. 3.—Globulin-albumin ratios plotted against sedimentation rate. No parallelism.

Fahraeus further states that he has determined the composition of the plasma proteins and the sedimentation rate in the same clinical cases and found that there was a pronounced parallelism between the amount of fibrinogen or serum globulin and the sinking velocity. No figures, however, are given and this appears to be true of the reports of numerous other investigators whom he states confirm his results.

All the patients we have dealt with have been those suffering from some form of rheumatic disease. Whilst no actual discrimination has been used in selecting the cases, the majority of the cases utilised have been those of rheumatoid arthritis. It is well known that in this condition the sedimentation rate is greatly accelerated; in gout it is slightly accelerated, whilst in true osteo-arthritis and fibrositis it is within normal limits.

METHODS OF ANALYSIS

The sedimentation rate was estimated by the following method. Eleven to twelve cubic centimetres of blood were drawn off with an oxalated syringe and transferred to a graduated centrifuge tube. After standing half an hour to acquire room temperature the contents were thoroughly mixed by repeated inversions and adjusted to 100 divisions (= 10 c.cm.). The fall in one hour after mixing was taken as the measure of the sedimentation rate for the purpose of this investigation. The room temperature varied from 15° to 20° C. and slightly affected the rate, but not enough to require any important adjustment of the results.

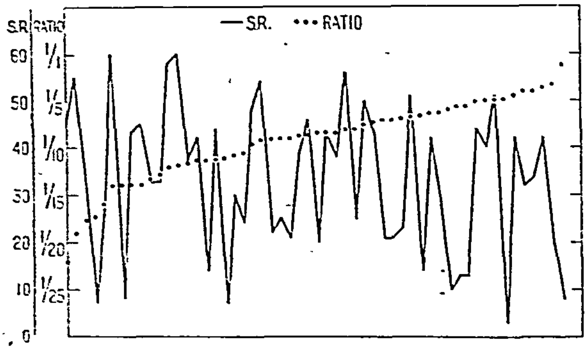

FIG. 4.—Fibrinogen-globulin (F/G) ratios plotted against sedimentation rate. No parallelism.

Plasma was obtained from the above specimen of blood after estimating the sedimentation rate, by centrifuging or allowing to stand overnight, the clear plasma from each sample being tubed off. Analysis of the proteins was immediately proceeded with. In the protein estimations the following procedure was adopted. As from 3–5 c.cm. clear plasma were available for analysis, micro-chemical methods were not resorted to. Wu's colorimetric method [7] based on estimations of the tyrosine factor in the three proteins was found unsuitable, but his ingenious method of separating the fibrin on a pointed rod was adopted. Gram,[8] who gets his fibrin as a round slab on thicknesses of filter paper by a similar method, determines it by direct weighing after two purifications and complete drying. We found it more convenient to determine the nitrogen on the pointed rod by digestion and nesslerising.

The whole scheme of analysis rests on four nitrogen determinations, the two larger amounts by Kjeldahl process and alternatively, the two smaller ones by modified digestion method and nesslerising. Ammonia-free distilled water was used for preparation of all reagents and dilutions, and reagent blank controls were made.

(1) *Total nitrogen.*—0·5 or 1 c.cm. plasma is delivered into a Kjeldahl flask from a capillary pipette graduated to 0·01 c.cm.; 5 c.cm. of (AR) H_2SO_4 added, with 3 drops of 5 per cent. copper sulphate, and digested until colourless, with or without, 1 g. K_2SO_4. After cooling, the mixture is transferred with the washings to a distillation flask, 40 c.cm. NaOH solution of sufficient strength to render alkaline added, and the NH_3 distilled off and titrated with N/20 H_2SO_4, using methyl-red as indicator.

(2) *Albumin nitrogen.*—1 c.cm. of plasma is measured with the same pipette as above, and delivered into a stoppered cylinder containing 30 c.cm. 22·2 per cent. solution of anhydrous Na_2SO_4 previously warmed in an incubator at 37° C. After three hours at 37° C. the mixture is filtered through a close filter and 15·5 c.cm. of filtrate (= 0·5 plasma) is transferred to a Kjeldahl flask and finished in like manner. Globulin and fibrinogen having been separated by Na_2SO_4, the nitrogen of the filtrate is albumin N and non-protein N.

(3) *Fibrinogen nitrogen.*—1 c.cm. plasma is delivered into a beaker containing 28 c.cm. normal saline, 1 c.cm. of 2·5 per cent. solution of $CaCl_2$ added, and the mixture is allowed to stand 30 minutes. The jelly thus formed is cut by small rod with pointed end and transferred gradually to small open filter, in which the rod is kept slowly rotating. Every trace of fibrin is collected on the point of the rod, which is then squeezed in a clean filter paper and transferred to a pyrex digestion tube containing 1 c.cm. digestion reagent (10 c.cm. 5 per cent. $CuSO_4$ solution, 100 c.cm. (AR) H_2SO_4, 100 c.cm. water). The pyrex tube is gently heated until dense fumes escape, cooled for 30 seconds, and 30 per cent. H_2O_2 solution added drop by drop until the liquid is colourless—two or three drops should be sufficient. The tube is then re-heated for a minute or two until dense fumes again escape, allowed to cool, and diluted to 85 c.cm., cooled, 15 c.cm. Wu's Nessler solution

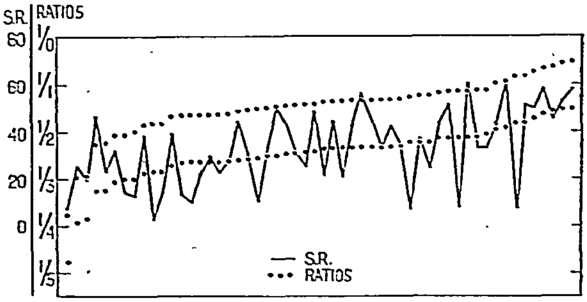

FIG. 5.—The upper black dots represent the ratios F+G/A; the lower represent F+G/total proteins. These two rows run parallel to each other, but not to the sedimentation rates.

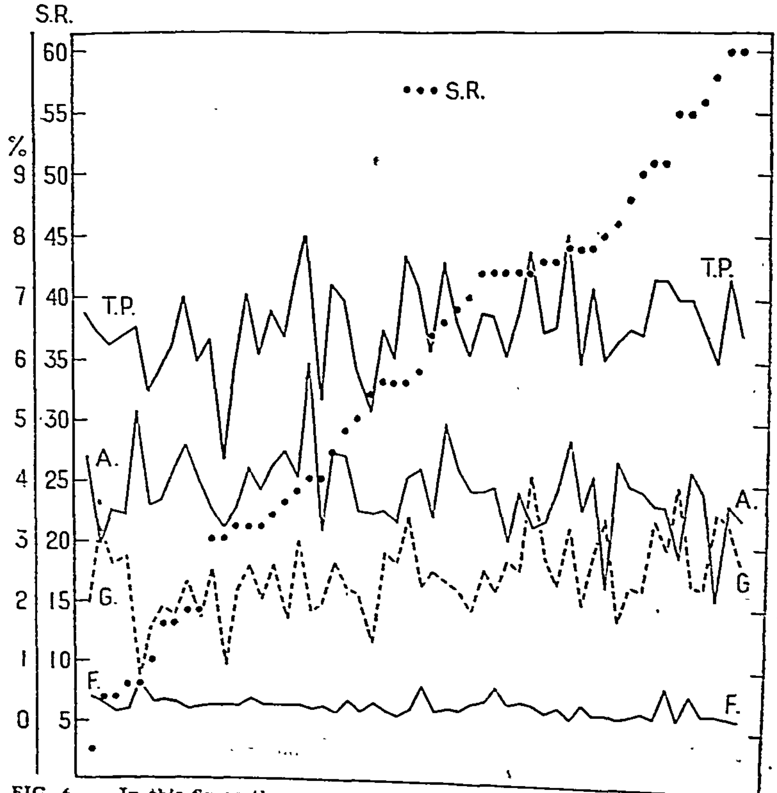

FIG. 6.—In this figure the aspect is reversed, for here it is the sedimentation rates of the 54 patients that are plotted in ascending order. Their steep rise is not paralleled by any corresponding rise in the percentages of total proteins (T.P.), albumin (A.), globulin (G.), or fibrinogen (F.).

is added, the tube is again cooled and ammonia measured in a colorimeter.

(4) *Non-protein nitrogen.*—1 c.cm. of plasma is delivered into a mixture of 5 c.cm. 20 per cent. trichloracetic acid with 4 c.cm. of water, thoroughly mixed, allowed to stand 30 minutes, and then filtered. 5 c.cm. of filtrate (=0·5 c.cm. plasma) are digested as under fibrin, cooled, diluted to 35 c.cm., again cooled, 15 c.cm. Wu's Nessler reagent added, again cooled, and a colorimetric reading is taken against 1·5 c.cm., standard ammonium sulphate (=0·01 mg. nitrogen per c.cm.) diluted to 35 c.cm. with water and made up to 50 c.cm. with Wu's Nessler reagent.

RESULTS

In 54 cases of rheumatic disease, the sedimentation rate has been estimated and the plasma proteins analysed. The graphs illustrating the values found show clearly that no parallelism exists between the sedimentation rate and the fibrinogen percentage (Fig. 1) or the globulin percentage of the plasma proteins (Fig. 2). Further, they show that the sedimentation rate has no connexion with the globulin-albumin ratio (Fig. 3), the fibrinogen-globulin ratio (Fig. 4), or the ratios of fibrinogen plus globulin to albumin and to total proteins (Fig. 5).

The findings are summarised in Fig. 6.

ON THE PROTECTIVE ACTION OF "BAYER 205" AGAINST THE TRYPANOSOMES OF MAN

BY H. LYNDHURST DUKE, O.B.E., M.D., Sc.D. Camb.
DIRECTOR OF THE HUMAN TRYPANOSOMIASIS RESEARCH INSTITUTE, ENTEBBE, UGANDA

PREVENTION is better than cure and successful prophylaxis is prevention on a large scale. Before the appearance of Bayer 205 prophylaxis against the diseases of man by the use of drugs, as distinct from sera and vaccines, could claim little or no success.

For many years the medical profession has been debating about the value of quinine as a prophylactic in malaria. In the tropics, at all events until lately, such was the uncertainty prevailing on this point that individual practitioners in one and the same tropical township often differed diametrically in their views on this all-important point, to the despair and confusion of their clients. The work of Yorke and MacFie (1924) was the first scientific warning that all might not be well with the time-honoured ritual, practised the world over by Europeans "east of Suez," of the 5-grain tablet taken each evening with the first "sundowner." Of recent years a commission of the League of Nations has studied this question experimentally, and in the third general report of the Malaria Commission the conclusion is promulgated that "No drug which is known, taken in harmless doses, can be guaranteed to act as a true causal prophylactic." Apart from malaria, protection against the diseases of man is limited in its effective operation to the day or so following the administration of the drug. An injection of stovarsol may protect against exposure to yaws or syphilis, but the effects are limited, and David Lees in his text-book on venereal diseases is by no means enthusiastic about its use in this manner. But with Bayer 205 and the trypanosomes of man the position is entirely different. What actually happens to the drug in the body the literature does not reveal very clearly. But we do know from direct experiment with monkeys, animals highly sensitive to *Trypanosoma rhodesiense* and *T. brucei*, that a single dose of Bayer given either subcutaneously or intravenously will protect for a month or more against the bite of tsetse cyclically infected with these trypanosomes. This fact places Bayer 205 in a class by itself as a prophylactic of unique properties and immense possibilities. It is the object of the research described in this paper to determine the full scope and value of the drug in the prevention and control of human trypanosomiasis.

EARLIER OBSERVATIONS

The early work on the action of Bayer 205 has been reviewed by Martin Mayer (1928), who summarises the main points bearing on prophylaxis as distinct from therapy. Kleine and Fischer's work in Northern Rhodesia in 1922 led them to abandon as unsatisfactory the oral administration of the drug. They found the intravenous and subcutaneous routes equally satisfactory. Mayer in his résumé recommends intravenous injection.

Kleine and Fischer showed that the injection into a monkey of 0·15 g. Bayer 205 protected the animal for two months against the bites of tsetse proved to be infective with *T. rhodesiense* or *T. brucei* (Kleine and Fischer, 1922). While working with the League of Nations Commission on Trypanosomiasis in Uganda and using a trypanosome of the *brucei* group from isolated wild tsetse on Damba Island on Lake Victoria, I obtained further evidence on this point (Duke, 1928).

> A healthy monkey, No. 21, received two doses of Bayer 205 intravenously, the first injection on Jan. 21st, 1926, and the second on March 30th. From May 31st till June 7th it was fed upon daily by a *G. palpalis* whose salivary glands were heavily infected with *T. brucei*. The monkey's blood remained free from trypanosomes, being examined daily in thick-stained films. On July 2nd and 3rd it was bitten by four flies carrying the same trypanosome. From July 3rd to 15th its blood remained free from trypanosomes, which appeared for the first time on the 16th, remaining more or less constantly present until the animal's death on August 4th. All the gland-infected flies fed upon this monkey had been previously proved to be readily infective to clean monkeys.

In this experiment two injections of Bayer 205 protected a monkey for 69 days against a trypanosome that was normally rapidly pathogenic to the species. The protection conferred by the drug wore off between the seventieth and ninety-fifth days after the last injection.

Experiments on a large scale on man were carried out in the Belgian Congo by Vanden Branden (1926–27) and by Van Hoof and myself (Duke and Van Hoof, 1928). These experiments consisted in the inoculation with Bayer 205 of a section of a native population living in an area known to be infected with *T. gambiense*, another section of this population being left untreated to serve as controls. Vanden Branden concluded as the result of his investigations along these lines that the protection conferred by a single dose from Bayer 205 lasted in man for some nineteen months. The Commission's experiment failed, for none of the controls became infected. Mayer considers that the evidence justifies the conclusion that a single dose of about 1 g. Bayer 205 per adult given intravenously will protect a man against *T. gambiense* from at least three months. He recommends that

TABLE SHOWING THE EXPOSURE OF VOLUNTEERS PREVIOUSLY INOCULATED WITH BAYER 205 TO CYCLICAL INFECTION WITH HUMAN TRYPANOSOMES CARRIED BY *G. palpalis*

** This fly was dissected the day after it fed on volunteer M. Both salivary glands were heavily infected and the alimentary canal was full of M's blood.

† Trypanosomes appeared in 1226's, 1227's, and 1229's blood 11, 9, and 8 days respectively after the first fly bite.

this dose be repeated every three months in those exposed to infection by cyclically infected tsetse in nature.

The Present Inquiry

The experiments now to be set forth were started in connexion with an investigation on the effect of long residence in antelope on the trypanosomes of man. Volunteers were used, and those who became infected were treated with Bayer 205 the moment trypanosomes were demonstrated in their peripheral blood. Three of these treated cases (A, B, and C in the accompanying Table) were chosen as the starting-point of the present research. Each of these men was infected with a strain of *T. rhodesiense* that had been for months in an antelope at the laboratory. In each case after an incubation period of eight to ten days trypanosomes appeared in the blood, and the patient complained of malaise and high fever (105° F.). The first dose of Bayer was given immediately trypanosomes appeared, and each patient received subsequently five more doses of 1 g. each dose at intervals of a few days.

Later on, at the conference held last November at Entebbe upon trypanosomiasis research in Eastern Africa, the examination of the prophylactic value of Bayer 205 was allocated to the Uganda Institute. Three healthy native volunteers were selected (I, M, and Q in the Table), and each received a single intravenous injection of 1 g. Bayer 205, and another treated volunteer (E) was added to the first list. In addition, three monkeys also received a prophylactic dose: 1226-27, 0·158 g. per kilo; and 1229, 0·023 g. per kilo body-weight.

The results of all these preliminaries are shown in the Table, in which are given the details of the exposure of each individual to infective tsetse. The numerals in the columns show how many gland-infected flies bit the volunteer on each occasion. Several strains of *T. rhodesiense* were used, and the infectivity to man of each batch of flies was tested on a separate, "clean" volunteer before the flies fed on the Bayer-treated subject. All the flies fed well, this being verified by observation and, in the case of the last feed of each insect, by dissection. Before being placed on the volunteer each fly was either starved for 48 hours and then given a second opportunity to feed on the following day, or was starved for 72 hours and then fed on the volunteer.

The honorary statistician to the research conference at Entebbe, Dr. C. H. N. Jackson of Tanganyika, expressed the opinion that for the results of this investigation to be statistically valid eight cases and eight controls would be sufficient, provided that 100 per cent. of the controls became infected and 100 per cent. of the inoculated cases remained uninfected. This estimate was based on the tacit assumption that all men are equal in their resistance to trypanosomes, a matter upon which recent research at Entebbe has thrown some doubt. This objection is in all probability negligible in the present investigation for the strains used were strongly pathogenic to man.

The Table shows that a single dose protected against *T. rhodesiense* for at least 113 days, and that those volunteers who had been treated with six doses of Bayer, after being infected for some ten to eleven days with *T. rhodesiense*, resisted all attempts at reinfection with different strains of *T. rhodesiense* for at least 190 days. On the other hand the monkeys both succumbed after 67, 69, and 74 days—in each case on their first exposure to infection after treatment with a single dose of Bayer 205.

The results obtained with *T. gambiense* are particularly instructive.

On the 113th day after receiving a single dose of Bayer 205, volunteer M was bitten by a fly carrying *T. rhodesiense.* On dissection the intestine of this fly was found to be full of M's blood and its salivary glands were heavily infected with flagellates, and had infected a volunteer before it bit M. M did not become infected, being still protected against *T. rhodesiense.* On the 145th day this volunteer was bitten by two flies whose glands were infected with *T. gambiense* strain LXII. Nine days later he reported sick; his temperature was 100° F. and he had a small tender swelling on the thigh where the flies had fed. Trypanosomes were found in the peripheral blood.

The administration of a single dose of Bayer 205 had therefore protected this man against *T. rhodesiense* for at least 113 days, but by the 145th day he was no longer safe against *T. gambiense.*

Turning now to the six-dose series of volunteers, we see that B was bitten by seven gland-infected flies carrying *T. gambiense* between the 208th and 212th days after the last administration of Bayer 205. Twenty-two days after the last of these flies had bitten him this man complained of mild indisposition and a small tender swelling on the forearm where the flies had fed. Trypanosomes were present in his peripheral blood. Thus volunteer B who was protected against *T. rhodesiense* for at least 180 days after the last administration of Bayer 205, by the 208th day possessed no defence against *T. gambiense.* It has not yet been determined how long protection lasts against *T. gambiense* in man; the only other experiment performed with this trypanosome being that upon volunteer C who resisted infection 38 days after his last dose of Bayer 205.

CONCLUSIONS

A consideration of the evidence now available suggests the following conclusions.

(1) That a single dose of 1 g. of Bayer 205 given intravenously will protect a man for at least 113 days from infection by tsetse carrying cyclically *T. rhodesiense.*

(2) That the administration of a second dose three weeks or so after the first enhances the protective effect of Bayer 205.

(3) That within certain at present undetermined limits the protective effect may be directly proportional to the number of doses given, although this point is not yet definitely settled. Three infected volunteers, all treated with Bayer 205 immediately trypanosomes were first detected in the peripheral blood and each receiving six doses of 1 g., were protected against *T. rhodesiense* for 180, 182, and 190 days respectively.

(4) That the natural sensitiveness of the mammal to the trypanosome plays an important part in determining the duration of the protection conferred by Bayer 205, the more susceptible monkey receiving less protection per dose per kg. body-weight than the more resistant man.

(5) It is probable, though not yet proved, that the protection conferred by Bayer 205 is greater against *T. rhodesiense* than against *T. gambiense. T. gambiense* is an old-established parasite of man and the power to infect him is a deeply rooted quality of this trypanosome, whereas recent research at Entebbe has shown that *T. rhodesiense* may in certain circumstances lose its pathogenicity to man. If, then, the resistance of man to *T. rhodesiense* is indeed greater than to *T. gambiense,* then this factor will in all probability tend to produce the effect suggested. It is also possible that *T. rhodesiense* is actually more sensitive to Bayer 205 than is *T. gambiense.*

Recent work at Entebbe has shown that strains of *T. rhodesiense* vary in their power to use man. It will be against the weakly endowed strains that the drug will be most effective, supplementing the natural resistance of the host. On the other hand *T. rhodesiense* strain LX, with which many of the tests in the Table were performed, was beyond all question strongly pathogenic to man, and only recently isolated from his blood. Protection against this strain is, therefore, a notable and an encouraging achievement.

At the present time, to be on the safe side, I consider that the prophylactic injection of 1–1·5 g. Bayer 205 per adult should be repeated every three months while exposure to infection continues. For biological reasons the strict enforcement of this period in *T. gambiense* areas is recommended. Where *T. rhodesiense* is concerned, I believe the protective effect of Bayer 205 will be greater than against *T. gambiense,* but it must be understood that this last is but an opinion and as yet unsupported by direct evidence.

The examination of these volunteers will be continued later on in the year, when this research will be resumed and extended.

Clinical and Laboratory Notes

STREPTOCOCCAL SEPTICÆMIA

TREATED WITH ANTITOXIN AND TRANSFUSION

By G. Gregory Kayne, M.D., M.R.C.P. Lond.

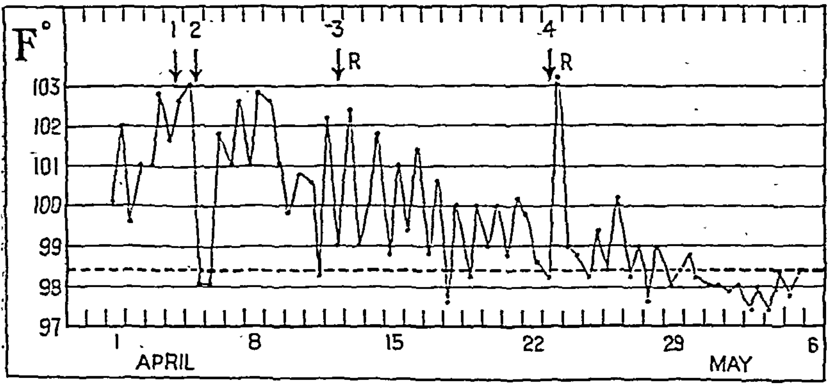
DOROTHY TEMPLE CROSS RESEARCH FELLOW IN TUBERCULOSIS; LATE ASSISTANT MEDICAL OFFICER, ST. CHARLES' HOSPITAL, LONDON

The attention drawn to the treatment of streptococcal septicæmia by articles in The Lancet of Feb. 24th and March 10th prompts me to record the following case.

Mrs. A., aged 39, was seen at St. Charles' Hospital on March 31st, 1933. Her last menstrual period had begun on Feb. 24th. She was found to be pyrexial, and a piece of tree bark was removed from the cervix by the medical officer on duty, who transferred her to a fever hospital as a case of septic abortion. She was, however, returned the following day as it was considered there that she had not aborted.

She was first seen by me on April 4th: temperature 101·6°; pulse 108; no vomiting; no rigors; bleeding from vagina; uterus enlarged; cervix admits one finger. Concentrated streptococcal (scarlet fever) antitoxic serum (Burroughs and Wellcome) 40 c.cm. was administered intramuscularly, and later, under a light general anæsthetic, the cervix was slightly dilated, several large pieces of placenta and membranes were removed with ovum forceps, the uterine cavity was explored digitally, and a hot intra-uterine douche followed by intra-uterine glycerin and pituitrin intramuscularly was given. There was considerable bleeding during the operation. An attempt to administer serum intravenously in the theatre failed; therefore on return to the ward the patient was given a further 60 c.cm. of serum intramuscularly, and treated for shock with morphia and subcutaneous saline.

April 5th: general condition very poor; very pale; temp. 103°; pulse-rate 118; no bleeding from vagina; hæmoglobin 41 per cent. Blood transfusion (350 c.cm. by Keynes's method), 50 c.cm. streptococcal antitoxic serum being given intravenously at the same time, by adding it gradually to the blood. The patient's temperature which had already been dropping since the morning was normal in the evening; pulse-rate 108; intra-uterine glycerin twice daily.



Temperature chart in streptococcal septicæmia. At 1 operation was performed and 100 c.cm. antistreptococcal serum was given intramuscularly. At 2 a transfusion was given and 50 c.cm. of serum was injected intravenously. Further transfusions at 3 and 4. R = rigor.

April 6th: general condition improved; temperature normal, rising to 101·8° in the evening; pulse 120; intra-uterine glycerin t.d.s., Blaud's pill grs. 30 t.d.s. April 7th: temp. 101°; pulse 114; lochia offensive; no vomiting; no abdominal pain. April 8th: temp. 101·4°; pulse-rate 120; respirations 28; nausea and headache; no physical signs in chest or abdomen; lochia very offensive; blood culture taken: growth of hæmolytic streptococcus reported on April 12th. Bluish-black area 3 in. by 2 in. on right buttock at site of intramuscular injection. April 9th: temp. 100° to 102·8°; pulse-rate 100–108; respirations 24; tender swelling over right scapula; Liveroid ½ oz. t.d.s. and ergot mixture prescribed. April 10th: temp. and pulse-rate dropping; discoloured area on buttock breaking down; lochia slight.

On April 12th the temperature had risen to 102·4°, with pulse-rate 120. Blood transfusion (500 c.cm. by Keynes's method) was done and there was a rigor immediately afterwards. Intra-uterine glycerin stopped. April 13th: temp. normal; pulse-rate 112; large sloughing area on buttock. April 15th: deep-seated abscess in region of scapula incised. April 17th: abscess right ankle incised; pus from abscesses reported later to contain *Streptococcus hæmolyticus longus*

On April 19th the temperature was still raised intermittently up to 100°; pulse-rate 90–100; very pale; no lochia. The abscess in the scapular region had tracked down the back and further incisions were made. A large deep ulcer was present on the right buttock. All wounds were irrigated or packed with eusol. On the 20th a large abscess on right buttock (below the level of the ulcer) was incised, and an abscess on the right side of head was drained. A blood count showed: red cells, 3,500,000; hæmoglobin, 46 per cent.; colour-index, 0·66; white cells, 8000; some anisocytosis, poikilocytosis, and a considerable amount of polychromasia seen in film; Arneth count shift to left.

When this blood count was reported on April 23rd, blood transfusion (400 c.cm.) was done. A rigor followed 20 minutes later. April 25th: temp. 98·8° to 99·4°; pulse-rate 90–100; all suppurating areas granulating well. April 26th: abscess right postero-axillary fold incised. May 8th: temperature normal since April 28th, but pulse-rate still 92–100. Blood count: red cells, 4,800,000 hæmoglobin, 64 per cent.; colour-index, 0·66; white cells, 13,000.

The patient's general condition continued to improve and the temperature remained normal; the pulse-rate also dropped to normal from about May 23rd, when all the wounds had healed and the excavated area in buttock had nearly granulated over. She was discharged on June 17th completely cured.

COMMENT

One is tempted to conclude that the administration of the streptococcal antitoxic serum played at least some rôle in limiting the progress of the infection, so that the septicæmia "became localised." The wound in the buttock, presumably due to trauma during the intramuscular injection in tissues devitalised by the general condition of the patient, may, in addition, have acted as a fixation abscess. It is my belief, as the result of experience in other cases, that it is important to *flood* the patient with serum *as early as possible* by giving a very large dose intravenously; but to obviate accidents due to hypersensitivity an intramuscular dose should be given three or four hours before. If an intravenous injection is given at once it is advisable to use a funnel and tubing, run in saline first, then add a drop of the serum (which is thus administered in very great dilution), and watch for symptoms indicating hypersensitivity. If all goes well, the amount of serum can gradually be increased till it is used full strength. It is hardly necessary to add that careful inquiries should always first be made in every case for a history of asthma, urticaria, and the like, and of previous administration of horse serum.

Personally I believe that 40 c.cm. of serum intramuscularly, followed by 60 c.cm. intravenously, is the average dose to employ as a routine in these cases.

I am indebted to Dr. Basil Hood for permission to publish these notes; to Mr. Arthur Gray, who was called into consultation; and to Dr. G. W. Goodhart for the pathological reports.

INTESTINAL OBSTRUCTION

WITH AN UNUSUAL CAUSE

By Tina Gray, M.B. Glasg.

DISPENSARY SURGEON AND HALL TUTORIAL FELLOW IN SURGERY, GLASGOW ROYAL INFIRMARY

On Jan. 17th, 1934, a woman aged 68 was admitted to Prof. Paterson's wards in the Glasgow Royal Infirmary with all the signs of acute obstruction.

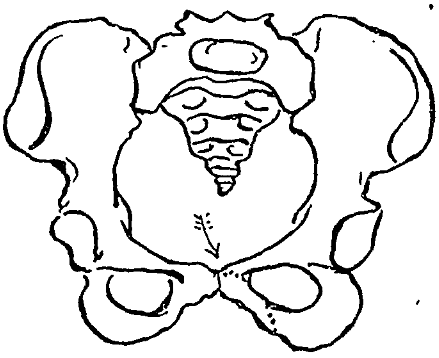
The history was as follows. On the evening of Jan. 16th she had been accidentally knocked down by a schoolboy. She fell, injuring her left side, but managed to get up and walk to her home, to reach which she had to climb two flights of stairs. She was seen by her doctor, who could find no definite sign of fracture and advised her to rest in bed: her complaint was that she felt her "inside being dragged," and not of pain. During the night she began to vomit, and the vomitus gradually changed from watery green to foul-smelling dark fluid. The patient, attributing her sickness to gall-bladder trouble, was not unduly alarmed. From the time of her accident her bowels did not act, and no flatus was passed; previously her bowels were regular. There was no discomfort with micturition and the urine contained no abnormal constituents. Immediately she was seen by her doctor on the 17th she was sent in to hospital.

When examined on admission, the patient, a frail old lady looking desperately ill, was found to be mentally very alert, and though articulation was difficult owing to the dryness of her tongue she gave her history accurately and was inclined to be rather voluble. Her general appearance was toxic. On examining the abdomen she was found to be profoundly emaciated, the skin of the abdomen having that sallow, waxy transparency so often seen with malignant disease. Distension was not marked, but peristalsis was obvious. The symphysis pubis seemed unduly prominent even for such a scaphoid abdomen, but there was no discoloration to suggest extravasation of blood. On palpation the abdominal wall was lax, and she complained of only slight general tenderness. Palpation of the symphysis pubis and left pubic ramus elicited tenderness; but no irregularity of contour could be made out. The vomitus was fæcal. The cachectic appearance of the patient suggested obstruction from malignant disease rather than an abdominal catastrophe due to accident.

Morphia and ephedrine were administered and she was taken into the theatre. When giving the spinal anæsthetic (3 c.cm. of 5 per cent. novocain) I found that she had a very definite lumbar scoliosis. The cerebro-spinal fluid was not under tension.

On opening the abdomen in the median line below the umbilicus, coils of distended jejunum presented. Following the distended loops I came on what at first seemed a firm adhesion to the symphysis pubis. On palpating a definite oblique ridge could be felt running downwards and outwards diagonally to which the bowel was attached. On shining a light into the pelvis a compound fracture of the left pubic ramus could be made out, into which the intestine was firmly wedged (see Figure), the entering loop distended, the other collapsed and worm-like. The peritoneum in the region was purplish and œdematous. It required a strong periosteal elevator to lever the fracture open so as to free the gut. The whole lumen and the edge of the mesentery had been caught, the ptosed condition of her viscera making the accident possible when the fracture gaped. The bowel was perforated in several places by the bone, and when the loop was delivered outside the wound liquid fæces poured from it.

I had to resect about 1½ in. of mangled gut and do a lateral anastomosis, closing the abdomen with drainage. Towards the end of the operation the patient's pulse became very feeble and pituitrin had to be given. She was returned to bed and the shock blanket applied.



The fracture followed the dotted line, and the bowel was caught at the point indicated by the arrow. (From a radiogram by Dr. A. Bruce-MacLean.)

Strychnine and digitalin and rectal salines were given four-hourly through the night.

The patient was definitely improved in the morning. Vomiting ceased after the operation. Her tongue was still very dry and she complained of thirst. Additional to water by the mouth, I gave her 600 c.cm. of glucose saline intravenously. Her bowels moved twice on the 18th after intramuscular injection of acetylcholine. The abdomen was slack, her tongue became moist, and her pulse improved in rate and quality. The improvement, however, did not last. She was rather restless through the night and collapsed in the early hours of the morning, and remedies proving useless she died on Jan. 19th.

I am indebted to Prof. Peter Paterson for permission to publish this case. I have not been able to find a similar one on record.

MEDICAL SOCIETIES

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

THE twentieth annual conference of this association, held in London on June 14th to 15th, discussed from many sides the

National Tuberculosis Scheme

of which we now have 21 years' experience. Sir HILTON YOUNG, who, as Minister of Health, inaugurated the conference, Viscount ASTOR who gave the opening address, and Sir ROBERT PHILIP, who presided, outlined the initiation, progress, and results of the work, leaving it to Dr. A. S. MACNALTY (senior medical officer, Ministry of Health) to fill in details from the public health and medical aspects. While the public, he said, still needed to be informed of the early signs and symptoms of tuberculosis, the outlook on the tuberculosis problem had been greatly changed by the realisation of the social and biological implications of the disease, and the appreciation of the fact that all measures directed towards the health and improvement of the nation generally were important contributions towards the prevention of tuberculosis. He brought forward two suggestions for special consideration in the national scheme: greater attention to contacts, and adequate provision of after-care. Dr. NOEL BARDSWELL (principal A.M.O., L.C.C.), in a survey of tuberculosis administration in London since 1913, drew attention to the L.C.C. scheme of boarding out children from infected homes, and to the provision made for the chronic ambulant, destitute, or homeless patient, in institutions such as Preston Hall.

Sir JOHN ROBERTSON (Birmingham) drew attention to the figures given by the Registrar-General in his last decennial summary (1921–23) of the comparative mortality from tuberculosis among employed and retired men between the ages of 20 and 65. These figures indicated that mortality from all forms of tuberculosis was two and three-quarter times as great among the unskilled as among the middle class, and that the mortality among the skilled artisan was nearly double that of the upper and middle class. This uneven distribution called for investigation; much greater care, he thought, should be taken for contacts in some areas. Young contacts should be kept under observation for as long as five years, facilities being available for those who needed special treatment. He would like to see a number of industries employing young persons—e.g., clerks and shop assistants—brought under the purview of the Home Office with a view to the establishment of more wholesome conditions of work.

THE DISPENSARY UNIT

Dr. G. **Lissant Cox** (Lancashire) discussing the dispensary unit—a better term, he thought, than tuberculosis dispensary—urged as a fundamental necessity that it should work in close association with the institutional unit. This was best attained when a graded medical staff controlled the united work. The disunity of the two sides of tuberculosis work—institutional and dispensary—was illustrated in London, where two separate authorities controlled them. One or other should control the whole. The most complete unity was achieved when the tuberculosis or dispensary officer and his assistants were in charge of a small institution, say 50 beds, in the area of the dispensary unit, each unit serving an area containing 200,000 to 300,000 in population.

Dr. D. **Melville Dunlop** (Edinburgh) recalled that the Departmental Committee of 1912 had laid it down that the dispensary should be a receiving house and centre of diagnosis. This it could only be if it commanded the confidence of the practitioners of the neighbourhood. The tuberculosis officer in charge should be a real specialist in tuberculosis, and not a medical Pooh-Bah. He should have full facilities at his disposal for making a difficult diagnosis, and sufficient time to make such a diagnosis accurate. No one could examine many new cases carefully at one sitting; in many dispensaries, not excluding his own, the hours were too short and too crowded, the dispensary being regarded by many as a sort of general out-patient department for the cure of coughs. Inflated attendances at dispensaries should be discouraged, (*a*) by omitting symptomatic treatment and concentrating on treatment of a specific kind—e.g., sanocrysin or tuberculin therapy, A.P. refills in certain definite cases; (*b*) by discharging the chronic bronchitic or asthmatic cases who came in shoals to the dispensaries for a chat and a bottle of cod-liver oil; and (*c*) by delegating to the home-doctor the observation of ex-institutional cases, to be seen at definite intervals by the tuberculosis officer. Properly paid officer and staff and adequate equipment demanded an outlay which might be prohibitive to small administrative units; he agreed that the solution was the provision of larger units. He felt strongly that the examination of contacts, particularly children, was among the really important functions of a dispensary. The weakness of the present-day position was the concentration on pronounced pulmonary lesions. But the tuberculosis officer interviewing the family might discover "delicate" children with a strong positive tuberculin reaction, who, though not suffering from pulmonary tuberculosis, were none the less suffering from the results of tuberculous infection; steps might be taken to forestall the visceral manifestations of the disease. Dr. Dunlop regretted that the tuberculosis dispensary and the school medical service were not in closer touch; the dispensary might well become an educational centre not only for the patient and his family, but for the medical student.

RESIDENTIAL INSTITUTIONS

Dr. **James Watt** (King George V. Sanatorium) said that two great factors were responsible for the revolution which had taken place in the residential treatment of tuberculosis of the lungs: the vastly improved technique of X ray photography which had relegated the stethoscope to a place of secondary importance, and the development of collapse therapy. All this had changed the character of the sanatorium from that of a convalescent home to that of a hospital complete with operating room, surgeon, and visiting specialists. The percentage of bed cases had risen from 20 to 50 per cent. or more, necessitating a standard of one nurse to six beds. The practice of graduated work by sanatorium patients had steadily become less common, although the value of occupational therapy was fully recognised. Nursing had greatly improved; systematic training in tuberculosis nursing, tested by examination at the end of a two-year course, was now available at most important sanatoria.

Dr. R. C. **Wingfield** (Frimley) said that much of the excellent work of the sanatoria was being wasted because there was not a close enough personal link between them, the tuberculosis officer, and the general practitioner. In the old days the sanatorium was an independent unit, and stood out as the only method of dealing with pulmonary tuberculosis. This independence and pre-eminence had been mistakenly perpetuated in most developments of the national scheme. The tuberculosis problem could only be solved by efficient coöperation in which the dispensary with its work in the field was the chief unit, the hospital and sanatorium definitely taking a subsidiary place. The present tendency to starve the dispensaries for the benefit of the sanatorium was unsound scientifically and uneconomic in practice. Any local authority that wished to tackle its tuberculosis problem efficiently must be prepared to spend at least as much on its dispensary as on its institutional service.

Dr. J. B. **McDougall** (Preston Hall) said that the meagre financial resources available for the bulk of after-care committees had frequently been one of the causes of their ceasing to function. After-care, using the term in its widest sense, had made less progress in point of efficiency than any other branch of the anti-tuberculosis scheme; the relapse of the patient might not be the fault of the sanatorium. It was, in fact, still to be learned that after-care was treatment, without which it was impossible to obtain the best results in at least half the cases. The essential object of the village settlement was to bring active disease to a state of arrest for a period sufficiently long to reduce to a minimum the liability of relapse. It was not a centre for the employment in perpetuity of arrested cases. Dr. McDougall thought the time had come for the N.A.P.T. to ask local authorities to choose between the schemes attempted with more or less success in this and other countries for the medical and economic benefit of consumptive patients. Knowing that after-care was sound clinical medicine, they should ask for larger contributions from national and local exchequers.

COÖRDINATION

Dr. H. P. **Newsholme** (Birmingham) indicated some of the channels of coördination which were desirable under the conditions of a large city. In Birmingham, where they had made the tuberculosis service into a unit, self-controlled and adjusted to an extent perhaps unusual in national tuberculosis schemes, there was a high degree of coördination between the sanatorium and the tuberculosis dispensary, in its character of clearing house. All admissions and transfers were arranged from the dispensary, whether it was a question of beds for sanatorium and hospital cases, for children, for surgical tuberculosis or for observation, including the transfer of tuberculous patients to and from general and special hospitals, municipal and voluntary. This reduced to a minimum the wastage from unoccupied beds.

REVIEWS AND NOTICES OF BOOKS

Investigations into the Causes of Mental Deficiency

By H. O. WILDENSKOV, M.D. London: Humphrey Milford, Oxford University Press. 1934. Pp. 113. 5*s.* 6*d.*

RESEARCH into the family histories of mentally defective patients is being carried out by an increasingly large number of workers in different countries. Systematic inquiries on these lines, however, in which each family is investigated with equal thoroughness, occupy much time. Few medical officers are able to carry out such researches, and, if they do, the work must extend over a period of many years. Dr. Wildenskov, who is medical superintendent of the Keller Institution in Denmark, has now published the results of five years of careful study. Fifty feeble-minded children and 50 idiots or imbeciles were chosen as *propositi;* naturally, larger groups would have been more spectacular, but the care with which these small ones were studied compensates for the absence of greater numbers.

Dr. Wildenskov started with the hope that he would obtain information on the question of the cause of mental deficiency in each case studied. Though he has not been successful in doing this, the data he has presented form a valuable background for future work. In each group of 50 children he investigated the incidence of dullness, feeble-mindedness, imbecility, and idiocy among the relatives. It is to be noted that the term "oligophrenia" includes dull as well as defective individuals, and that it can be applied to anybody with an I.Q. below 90. Comparison of the two groups shows striking differences. For example, oligophrenia was much more frequently found among the parents and sibs of high grade or special school-children than among the corresponding relatives of low grade patients. For special school-children about 50 per cent. of the sibs were oligophrenic; for idiots only about 25 per cent. were oligophrenic. Similarly, for high grade mentally defective children, 37 per cent. of the parents were considered oligophrenic, whereas, for low grade children, only 12 per cent. of the parents came into this category; even when cases of obvious secondary amentia among the idiots were left out, not more than 15 per cent. of the parents were oligophrenic. The same type of phenomenon was observed when more distant relatives were investigated.

These results are introduced by a careful survey of the literature on the ætiology of mental deficiency. Dr. Wildenskov shows that there is a consensus of opinion that inheritance, traumata, and inflammatory conditions of the brain are causal factors. There is no agreement, however, about the ratio of distribution of these causes. Authorities disagree about the importance of syphilis and alcohol. It is pointed out that the traditional division of cases into primary and secondary amentia needs revision, and that the combination of hereditary and acquired amentia is common. Many investigators have expressed their opinion that exogenous causes play a greater part in the causation of idiocy than in the causation of feeble-mindedness. This view was expressed in the Wood Report, and can be traced in the writings of Larsen, Szondi, and many others. There can be no possible chance of settling what percentage of patients is due to exogenous causes in any grade until there is agreement about what are to be the criteria of hereditary influence. In presenting the results of his researches, Wildenskov leaves this point undecided. His material undoubtedly shows that the incidence of defect is greater in the families of the high grades than in the families of the low grades, but if the families of the *propositi* are grouped according to whether one or both parents are oligophrenic the difference in familial incidence among the children, for high and low grade *propositi*, is scarcely significant. We are almost forced to the conclusion that, if the incidence of defect among the children of defectives is a criterion of hereditary influence, heredity must be almost as potent a cause among low grade as among high grade cases. Is it not possible that the phenomenon which Wildenskov, in common with so many observers, has noticed is partly due to the selection of cases who enter institutions? The remainder of the effect might be due to the fact that low grade patients seldom themselves have children, and that recessive characters are more likely to be discovered among the low grades.

The monograph is a stimulating and original piece of work, and it is obvious that no trouble has been spared in order to arrange the data in a useful way. The subsidiary problems, such as the incidence of epilepsy among sibs of defectives and the diagnosis of amentia due to trauma or cerebral infection, are treated in an interesting way. Dr. Wildenskov concludes by saying that he thinks future work on mental deficiency ought to be based on material that is uniform as to the degree of defect. A good bibliography of recent papers on the subject is supplied.

Diseases of the Eye

Seventh edition. By Sir JOHN HERBERT PARSONS, C.B.E., D.Sc., F.R.C.S., F.R.S., Consulting Ophthalmic Surgeon, University College Hospital; Consulting Surgeon, Royal London (Moorfields) Ophthalmic Hospital. London: J. and A. Churchill. 1934. Pp. 695. 18*s.*

IN its seventh edition this popular text-book retains its character of a sound conservative statement of all branches of ophthalmology. The subject matter includes anatomy, optics, the neurology of vision (a strong chapter this), methods of examining the eyes (the slit lamp is mentioned but not described in detail), many chapters on diseases of the eye and its adnexa, ocular disorders of motility, ocular manifestations of diseases of the nervous system and of other diseases, and finally on the causes and prevention of blindness and the hygiene of vision. Possibly in the next edition some information on the certification of blindness might be added. Recent advances are noted but the advanced student will have to turn to more specialised works for detailed descriptions. The chapter on physiology has been largely rewritten in this edition; it is devoted mainly to a discussion on the formation of the intra-ocular fluid and its relation to intra-ocular pressure. The dialysation theory of Duke-Elder is favourably considered, the conclusion reached being that both dialysation and filtration play a part in the formation and disposal of the intra-ocular fluid and the maintenance of intra-ocular pressure. In the chapter on glaucoma the pathology is discussed on orthodox lines, the chief stress being laid on interference with filtration at the angle of the anterior chamber. The student who reads the chapter on detachment of the retina might hardly realise how greatly the prognosis has improved since the discovery by Gonin of the importance of retinal holes and of the methods of closing them.

The statement in the text that the best of these methods is probably diathermy will be fully endorsed by ophthalmologists.

This work retains its vitality, and the student who adopts it as his main text-book on ophthalmology is not likely to regret his choice.

Le sinus carotidien et la zone homologue cardio-aortique

By C. HEYMANS, Professeur de Pharmacologie et de Pharmacodynamie à l'Université de Gand; J.-J. BOUCKAERT, Professeur de Thérapeutique générale à l'Université de Gand; et P. REGNIERS, Agrégé de l'Université de Gand. Paris: G. Doin et Cie. Pp. 334. Fr.55

THIS valuable monograph is a synthesis of the principal facts established concerning the rôle of cardio-aortic zones together with a detailed account of the recent researches conducted by the authors at the Gand University. The problem has been approached from various aspects, and detailed and careful records are given which should be extremely useful. The book is divided into five sections. The first part deals with the morphology of the carotid sinus and cardio-aortic zones not only in man but in a large group of animals. The next section is concerned with the physiological functions of these zones under the headings of their relation to the circulation and to the activity of the respiratory centre; thei reaction to physiological chemical substances, as fo example Ringer's solution charged with CO_2 or insufficiently aerated blood; their influence on other physiological functions, as for example on the gastro-intestinal, ocular, and pupillary reflexes; and finally their influence on the equilibrium of the autonomic and sympathetic systems. The third section deals with the pharmacological aspect of these zones, most important from the point of view of the physician and the anæsthetist. To give one small example of its clinical bearing, it appears that the cardio-inhibitor reflexes are intensified during chloroform or ether anæsthesia; this is of particular moment in operations on the neck, particularly in cases of hyperthyroidism where the surgeon may by traction on the gland excite the carotid sinus reflex and produce hypotension and strong cardiac inhibition. The fourth section deals with the principal factors, physiological and pathological, which may modify the reflex function of the cardio-aortic and carotid sinus zones, also the effect of section of the nerves which innervate them. The final and most important chapters discuss the clinical aspect of these zones. A correlation is attempted between experimental findings and clinical conditions. We are still, however, only on the fringe of discovery as to the workings of these reflexes, and the practical application of most of the research described is still to seek.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

VII.—THE POLITICAL OUTLOOK

LEGALISATION of eugenic sterilisation in this country has been definitely "put on the map" by the first recommendation of the Departmental Committee which runs:

> "Subject to the safeguards proposed, voluntary sterilisation should be legalised in the case of: (1) a person who is mentally defective or who has suffered from mental disorder; (2) a person who suffers from, or is believed to be a carrier of, a grave physical disability which has been shown to be transmissible; and (3) a person who is believed to be likely to transmit mental disorder or defect."

It may be well to consider what appears to be the prospect of legislation upon this subject. Political prophecy is always a hazardous business, never more so than in these times when so many events without precedent or probability occur, and when domestic no less than world politics are subjected to turns of the wheel of fortune such as no man could have anticipated as being even remotely possible a decade ago. There is a further factor for which allowance must be made in trying to form this estimate, which is that the opinion of any would-be prophet is liable to be subconsciously influenced—more upon this subject than upon most—by his or her personal views in the matter, so that the wish is very liable to be the father of the thought.

GROWTH OF PUBLIC OPINION

The objector to sterilisation, who usually takes an uncompromising stand upon religious grounds, will assert that the operation is so immoral that its legalisation is unthinkable, and that such is the organised voting strength supporting his point of view that no Government will dare to risk taking action. The person, and especially the recent convert to the idea, who sees in the sterilisation of hereditary defectives a clear road to social progress, and to a substantial reduction in the sum of human misery, tends to under-estimate the difficulties, political and legislative, and to become an enthusiast who notes the rapid growth of favourable public opinion and concludes that the time is ripe for parliamentary action.

The growth of opinion in favour of sterilisation has certainly been very remarkable during the last few years. Although the two subjects can only be indirectly connected, there is no doubt that it is the almost universal spread of the knowledge and practice of birth control throughout the population that has paved the way for interest in sterilisation, and has created a public which is receptive to what would only a few years ago have been regarded as unthinkable. The present-day readiness to consider sex problems as natural and to be discussed in a rational manner has, of course, played its part. Not long ago, even among educated and thinking people, few had even heard of sterilisation except by castration, or were ready to give the question of human sterilisation serious consideration even if it were brought to their notice. So far as serious consideration was concerned this applied even to the bulk of the medical profession. To anyone who was interested in the subject in those now seemingly remote days the change that has taken place, and is taking place, in public opinion is nothing short of miraculous. Publication of the Brock report has crystallised the issues. What had so recently been the vague beliefs of a few people commonly regarded as cranks, supported by evidence of doubtful reliability, and by statistics not fairly comparable to British data, received the endorsement of an impartial and weighty committee after a thorough and objective survey. While some previously held views had to be modified, others were reinforced; while some old evidence had to be discarded, much fresh and weighty evidence was produced. But at least the protagonists of eugenic sterilisation could feel for the first time that they stood upon indisputably firm ground.

PARLIAMENTARY PROCEDURE

It is interesting to look back at the first attempt to bring the question before Parliament. On July 21st, 1931, Major A. G. Church, then a member of the Medical Research Council, introduced from the Labour Benches a private Member's Bill under the rule which allows two speakers, one for and one against, both limited to 10 minutes. This Bill, which sought to legalise voluntary sterilisation for mental defectives, was rejected by 167 to 89, with voting irrespective of party. A Bill introduced under the "10 minutes' rule" has in reality a negligible chance of being passed into law if it is faced with the slightest opposition. Indeed, the procedure is used mainly for propaganda, and for this purpose it is not so futile as it may appear to those critical or ignorant of parliamentary procedure. With very few exceptions only measures introduced by the Government of the day, with its full authority, and with a previously ascertained confidence of general assent from its supporters, stand any chance of becoming law. Many complaints are raised nowadays at the slowness of parliamentary procedure, but it may be doubted if many of those who complain realise the full implications of their demand for speedier action. Few will disagree that we suffer from too many, and not too few, laws. The existing practice, that at first glance may well appear to be so cumbersome, has in reality been evolved through the centuries with two main objects in view. First, to ensure that there shall be adequate opportunity for the discussion of all measures before they can be passed into law, and to ensure that no minority shall be ruthlessly overridden by a large or impetuous majority. Secondly, to fix the responsibility for all legislation upon the Government of the day. It is when subjects are brought forward that cut across ordinary party alignment, as where religious issues are involved, e.g., in divorce law reform, or in a reform of the gambling laws, that any Government is embarrassed and becomes hesitant. A party depends upon votes, and upon such issues votes can only be lost and not gained. Normal supporters may be disaffected, but normal opponents are not to be won over. The stormy passage threatening the recently issued Bill to deal with betting and lotteries is a case in point. In this case refuge had been taken in the usual Royal Commission. And had action of some sort not been forced upon the Government by such serious gaps discovered in the existing (and obviously obsolete) state of the laws as that which permitted the huge annual exit of money to Dublin over the Irish sweepstake, or by the discovery of certain interests that they could circumvent the law against the (promiscuous) use of their own totalisators, it can hardly be doubted that the issue would have still been shunned.

It is into this category of cross-party measures, and closely comparable with divorce law reform, that legislation upon sterilisation must be put. It may be safely assumed that an overwhelming majority would like to see a rational reform of the divorce laws. Yet they may not see it for many years. Sterilisation will probably be saved from such delay by reason of the greater weight of general public interests, as opposed to scattered private interests that is involved. But for this fact a resolute minority, even if small and diminishing, would certainly deter any Government from taking action, despite the fact that there is already in the House of Commons, and probably in the country, a majority in favour of action upon the lines of the Brock Committee. When Major Church's bill was introduced the Labour section of the Opposition in it fastened upon "class legislation" as being the line to take in the attack. I is probable that on the whole labour-socialis more advanced in favour of sterilisation than t opponents. But the average Labour Membe Parliament, or candidate, is far less free to ex his personal views, or to take the slightest risk, his conservative opposite number. In the pre vague state of opinion upon sterilisation in country few members of any party will gratuito risk losing even a few hundreds of votes. But it m be observed that in the few constituencies wh sterilisation has as yet been squarely put and expla to the electors, it has been very well received. H ever, in the same way that the belief has captured t imagination of so many Labour voters that a restr tion of births will tend towards raising the status o the wage-earner, so is a realisation spreading of t more easily established truth that unorganisable an (with exceptions) unskilled defectives—some approaching 250,000 of them in the labour mark to-day—are a drag upon wage standards and progress, a burden upon the social services.

ALLEVIATION OF FEARS

At the present time, omitting opposition upo religious grounds—which except perhaps in the cas of the Roman Catholic Church is rapidly declining—the cries of objection to legalising eugenic sterilisation that the politician fears are broadly three in number. First, "class legislation," a declining and surmountable objection. Secondly, the charge that it will not prove possible to maintain the voluntary character of the operation. Thirdly, that grave abuses will creep in, such as increased prostitution, promiscuity, or sex offences, and the spread of venereal disease. It will only be when the answers to these fears—all, of course, faithfully dealt with in the Brock report—have attained as wide a circulation as the fears themselves, that any Government will dare to introduce legislation. It is probable that the public will get clear upon these points much more rapidly than is generally supposed. Only those who have made it their business to feel the public pulse upon this subject over a period of years can appreciate how rapid is the quickening that is now taking place. Improvement in the means of ascertaining mental defect, and the increasing realisation of its extent, coupled with need for scrutiny of every item of expenditure, is converting local authorities and charitable organisations (though these latter hesitate to announce the fact) wholesale to taking a favourable attitude towards sterilisation as a way of reducing their burdens. The circulation of the Brock report has f exceeded anticipation. The medical and teachi professions have swung over and will increasing exercise their influence upon the public. There indeed, a danger that demands will be made to app sterilisation far more widely than sure knowled justifies, and with the expectation of results beyo the possibility of realisation. But the object less provided by recent German eugenic legislation help our own people to keep a proper sense proportion. The success of sterilisation in pract in Alberta, its progress in other dominions and the Scandinavian countries, will be closely watch in this country.

It is then to outside Parliament that we must loo at present in estimating the prospect of legislation Political action in this field as in others will follo and not lead public opinion. Unforeseen events ma hasten or delay enactment—the example of th Betting Bill is not without significance—but of legalisation of eugenic sterilisation is certain to em.

THE LANCET

LONDON: SATURDAY, JUNE 23, 1934

SUICIDE

THE problem of suicide is an insistent one in modern society. It has for many centuries been examined by moralists, physicians, and jurists. It is appropriate that it should now also hold the attention of statists and sociologists for they are closely in touch with those predominant burdens that contribute to the greater prevalence of suicide in our civilisation, especially among those who live in cities. The statistician of the Metropolitan Life Insurance Company has lately published a valuable contribution to this subject [1]; it may be supposed that he was led to this study by consideration of the fact that American life insurance companies paid over 75 million dollars in suicide claims during 1932. Access to the records of a very large insurance company has provided him with material from which it may be seen, as from the Registrar-General's reports in this country and other statistical data, that the frequency of suicide is influenced by a number of environmental factors of which industrial conditions are not the least important. But, as was pointed out recently in these columns, the exact relations between mental disorder and unemployment must be to a varying extent a matter of surmise. One cannot hope from statistics for a clear indication of the chief causes of suicide, but significant correlations emerge from these figures. How far racial and climatic peculiarities are responsible for variations from country to country is not clear, but such variations are notable. The highest rates are found in Germanic countries and Japan, the lowest in Spain and the Irish Free State. Where an authoritative highly socialised religion is widely observed, suicide is less common. Men are more prone to suicide than women, older people than young, white men than negroes, immigrants than settled inhabitants, and city dwellers than rural ones. The seasons, economic conditions, marriage, and religion all show a relatively high correlation with the suicide rate. It is very clear, for example, that the suicide rate in the United States has varied in close relation with the "business index" between 1910 and 1930. But from such a general finding Dr. DUBLIN refuses wisely to infer a simple causal relation.

The sobriety of statistical analysis is refreshing in a field where psychological conjecture is sometimes undisciplined, as may be seen from the latter, vaguer part of this book. It is incontestable that there are also inner or constitutional factors which are of equal importance with the environmental ones in determining suicide. There are so many circumstances in which suicide may be attempted, such a gulf often between the attempt and the lethal act, that no single explanation or simple cause can be sufficient. Those who deliberately, and it might be said rationally, act to avoid what would be unendurable, cannot be accounted for in the same way as an obsessional who yields to a suicidal impulse or a schizophrenic who obeys a hallucinatory voice. All of these are open to psychological study, from which much may be learnt, but there is still no psychological interpretation which covers all the phenomena. Many such interpretations are fanciful and cannot be verified, others provide the means for a useful estimate of the risk of suicide in a particular distance. The full interpretation of suicide must be a biological one, derived from a pooling of genetic, social, comparative, and psychological data.

The prevention of suicide is an urgent matter, for in this country as in many others the number of people who kill themselves is apparently increasing. Doctors have here an important part to play. Social and religious factors are not within their control except in so far as they are also citizens. But that large number, possibly the majority, of suicides who have sought medical advice for a mental illness, however mild or masked the suicidal aspect, must be regarded as a special responsibility. There is no doubt that ignorance of psychiatry is responsible for ill-judged advice sometimes given to patients who need hospital or at any rate skilled supervision. A sea-trip, an exhortation, or a placebo is no substitute for constant care and psychiatric treatment. Although it cannot be denied that in many cases the likelihood of suicide could not have been foreseen by the most experienced psychiatrist, there are others in which timely measures could have been taken. Fuller knowledge of the psychiatric indications is therefore much to be desired so that the doctor, without being an alarmist, can either warn relatives and advise treatment, or, it may be, reassure where there is needless alarm.

DIURNAL INCONTINENCE IN WOMEN

ONE of the most distressing sequelæ of damage to the pelvic floor in women is lack of complete control over the sphincter of the bladder, leading to incontinence of urine when walking, coughing, or engaging in other activities involving abdominal strain. Although the symptom is not unknown in young women and in those who have not borne children, it is much more commonly found in women over forty, especially in association with a history of frequent labours. The patient with incontinence may show evidence of cystocele, but, as is pointed out by J. THORNWELL WITHERSPOON in a recent communication,[1] it is quite usual for either condition to occur separately. Any severe degree of prolapse is, in fact, more likely to be complicated by retention of urine than by incontinence. Examination of the patient complaining of incontinence may reveal no abnormality until she is asked to strain in the squatting position. The characteristic displacement, as originally described by VICTOR BONNEY, is then a wheeling of the organs around and under the subpubic angle until the urethra comes to point upwards and forwards. Damage to the anterior wall of the vagina at the time of parturition may be caused by the forward pressure of the fœtal head; it may even be accentuated by efforts to save the perineum. This injury commonly involves the fascial supports of the bladder, but Witherspoon holds that the damage causing incontinence alone is at a different level from that causing cystocele alone. True cystocele is a hernia of the bladder between the fascial layers, and only when it is associated with weakness of the posterior aspect of the neck of the bladder and of the urethra is it likely to be complicated by incontinence.

---

[1] To Be or Not To Be. A Study of Suicide. By Louis I. [illegible]n, Ph.D., and Bessie Bunzel, M.A. New York: Harrison [illegible] and Haas. 1933. Pp. 443. $3.50.

[1] Archives of Surgery, 1934, xxviii., 548.

The fascial sheath which surrounds and supports the bladder is a much firmer structure anteriorly, where the trigone and the anterior part of the bladder lie on it, than posteriorly, where it separates the bladder from the vaginal wall. In front there is a strong attachment of the sheath to the pubic bone and to the under surface of the fascia of the rectus abdominis and of the pyramidalis, and at the sides it is attached to the levator ani. The sphincter muscle lies embedded in the supporting structures of the trigone, so that injury to these structures is likely to involve the sphincter and the bladder neck. With such damage, caused as it commonly is by pressure from behind, there follows a relaxation of the neck of the bladder, a dragging on the fascial attachments to the pubic bone anteriorly, and a funnel-shaped deformity at the neck of the bladder. The sphincter is acting at a mechanical disadvantage and tends to be relaxed. A reflex nervous factor then complicates the condition, for, once a little urine passes the sphincter, immediate cessation of micturition is very difficult to achieve on account of an involuntary inhibition of sphincteric control. Weakness of the anterior vaginal wall is liable to produce the same funnel-shaped deformity of the bladder neck. The cervix may be pushed downwards piston fashion every time there is an increase in intra-abdominal tension and may cause a dragging action on the base of the bladder. Weakness of the perineum has not this effect, and from the point of view of treatment, it is important to realise that perineorrhaphy is powerless to cure incontinence, although, of course, perineorrhaphy and colporrhaphy should be combined with the operation for lack of sphincteric control where necessary.

The operation recommended by Witherspoon aims at narrowing the neck of the bladder and the urethra and establishing a "point d'appui" for the action of the sphincter. A curved incision is carried round the anterior lip of the cervix and another incision made at right angles to it. The base of the bladder is exposed by dissection. The urethra, and especially the position of the sphincter, is defined by insertion of a Pezzer catheter. By means of two tiers of mattress sutures the tissues of, and those adjacent to, the neck of the bladder are enfolded and imbricated on themselves. One stitch is carefully placed above the sphincter on the neck of the bladder. By means of the plication effected by these stitches the sphincter and the posterior urethra are narrowed. As much as possible of the musculo-fascial sheath below the bladder is preserved and this is imbricated on itself. The mucous membrane edges are trimmed and united. An in-dwelling catheter is employed for six to eight days, or, alternatively, the patient is treated by frequent catheterisation. The results which Witherspoon has obtained by use of this method have been encouraging. In 13 cases, he says, the end-results are as yet undetermined, but of 21 others, there are only 2 failures, 14 are cured, and 5 improved. He stresses the importance of early repair of any damage occurring at the time of parturition. This should, in his opinion, be carried out as soon as involution has taken place.

A MIRROR FOR DOCTORS

In the MacAlister lecture, printed upon another page, Dr. ROBERT HUTCHISON has brought together an anthology of literary references, complimentary or otherwise, to the medical profession. The apparent predominance of the uncomplimentary will cause neither anxiety nor surprise. Famous wits produce their most memorable pleasantries when a spice of malice seasons the epigram; and a single patient's misadventures give the cynics a better opportunity than ninety and nine cases that go not astray. As the lecturer observed, the statistical proportion of praises to dispraises is perhaps the less important, inasmuch as one side of the ledger tends to cancel out the other. Some of the disparaging remarks originated a long time ago in a less scientific age. We may hope, with Dr. Hutchison, that doctors have risen in esteem as they have gained in efficiency. It may be true, as he suggests, that the individual practitioner is better liked than the profession as a whole; criticism is mainly the result of inability to understand the medical attitude towards lapses in professional conduct and towards excursions into therapeutics by the unqualified. That the attitude is the expression of the intention of the law eternally escapes comprehension.

A recent writer scarcely encourages the medical profession in self-complacency. In "The Citizen and the Law" by "Solicitor"[1] a vivacious chapter is devoted to doctors. The author, though his anonymity prevents any comparison of his credentials with those of Lord MACMILLAN, who lately put in a kind word for the medical profession,[2] has evidently met the medical witness in the county court, at petty sessions, and before the coroner. While instructing the citizen in the law not only as it is but also as it might be, "Solicitor" frames a *general indictment against doctors*, even if he finds it his duty to mention certain circumstances in mitigation of punishment. Doctors, he says, have lost caste. Publicly they are praised and lawyers are reviled, but in private conversation the converse is apt to occur. Many of his adverse comments are connected with a similar contrast between the two professions of law and medicine. It is notorious, he says for instance, that medical experts will charge for giving evidence in workmen's compensation cases double the sum earned by learned counsel for conducting the whole proceedings; hence, he remarks, it is small wonder that doctors "are not so highly thought of as they used to be." Of medical remuneration in general he complains that the legal basis of fees—entitling the practitioner to whatever the jurymen think reasonable, regard being had to his eminence and the distance he has to travel—leaves doctors free to charge pretty much what they please. "The extent of what, if they were lawyers, would be called their extortions is limited only by competition among themselves"; in country districts the charges are sometimes "astounding." He adds, in words which will be reassuring to some of our readers, that it is generally useless to defend an action brought by a medical practitioner to recover his fees. "Solicitor" would be more than human if he did not point out that lawyers' bills can be reduced on taxation while doctors' bills cannot. He would like all doctors' bills to be reviewed by district commissioners, and he cannot see what valid objection the medical profession could make to his proposal. There are plenty of other counts in the indictment besides avarice. A brief reflection on unnecessary surgical operations is followed by allegations of abuse of professional secrecy. The standard here with regard to hospital patients is described as deplorably low. Doctors, it seems, collect information in the hospital wards which is afterwards used against the patient in workmen's compensation and accident cases. The worst offenders in this respect, says "Solicitor," are the eminent specialists who are retained by insurance companies and who, by using knowledge gathered in whatever hospital they adorn, have shaken the confidence of the working classes in our hospital system.

---

[1] The Citizen and the Law. By Solicitor. London: George Routledge and Sons, Ltd. 1934. Pp. 249. 7*s.* 6*d.*

[2] See THE LANCET, May 19th, p. 1071.

"Solicitor" in support of these charges is without evidence which would stand an elementary cross-examination. Who are those eminent specialists, and what proof is there that their pliability has earned the distrust of the public? Again, what reductions in fees do solicitors give to clients who cannot afford to bring their distresses into the arena of the law courts without substantial help? It is considered reasonable for a solicitor to say, "I will not work unless I am paid," while anything approaching such an attitude on the part of the doctor is called callousness. Coroners' juries, if unfortunately an inquest should arise, are sometimes more pictorial in their estimate of the doctor's conduct. And when "Solicitor" speaks of the astounding charges made by eminent doctors for giving medical evidence, reasonable people, and especially people with legal minds, would suggest that if a particular specialist is invited to give evidence and a particular barrister is entrusted with a client's interests, the charges in either case will be high, and possibly those of Buzfuz will be higher than those of Firmin. "Solicitor" attributes a decline of the medical profession in public esteem partly to the introduction of the panel system, which has resulted, he says, in inferior care being bestowed on the less remunerative patients; he appears to be unaware of or unfairly silent upon the plight which those patients submitted to before the passing of the Act. Another cause of diminished prestige is declared to be the scandal of expert evidence. Here, as might be expected, we are told of the usual two eminent doctors who enter the witness-box and declare upon oath that there is nothing wrong with the workman and that work will be the best thing for him, though presently two equally eminent witnesses, also upon oath, state their conviction that any exertion on the workman's part will be certainly injurious and probably fatal. We all deplore this sort of discordant testimony, but medicine is admittedly not an exact science, and advocates search to bring about exactly the confusion described.

In case any should take "Solicitor's" comments too seriously, as from one qualified to criticise, we might add that evidence for qualification is lacking or even negative. For example, "Solicitor" states that vaccination is "often the cause of encephalitis lethargica," and cites, when speaking of the standard of professional skill and training, an anonymous general practitioner as an authority for the statement that any good plumber could be taught to be a surgeon in six months. We might perhaps have begun with this sample of "Solicitor's" capacity for writing accurately on the relations between the doctor and the public, and then have said no more.

MEDICAL MUSEUMS

THE International Association of Medical Museums was founded in 1907 and under the enthusiastic care of Dr. Maude Abbott it has done most useful service. The membership of the Association is not large: there are only 23 names under "Great Britain" in the list. But those who have a real passion for museum work are few, and for the most part pathological museums are rather perfunctory collections of bottled specimens which serve as texts for teaching and examinations. No museum however perfect can of course replace the assiduous study of the fresh post-mortem, where so much is learned from colour, texture, and substance. But there are many conditions with which it is desirable that the student should have at least some objective acquaintance which chance will not throw in his way, and no one who has seen such exhibitions as that of Dr. S. H. Daukes in the Wellcome building can doubt that all curators might with advantage reconsider their methods of presentation. No museum will be much good unless someone is putting his heart into its perfection and giving it the continuous loving care which it needs. And such an organisation as the International Association is valuable because it keeps curators in touch with what other devotees are doing elsewhere and with the technical methods which they elaborate. The last number of their publication—the *Journal of Technical Methods and Bulletin of the International Association of Medical Museums*—issued from McGill University in Montreal announces some changes in policy. The journal will in future be issued regularly once a year and its scope will be more strictly limited to museum and pathological technique with, we are glad to see, the congenital abnormalities of the heart in which Dr. Maude Abbott has so happily specialised. The number contains a great deal of interesting information and provides much and varied proof of the value of the work which the International Association has done and proposes to do.

ANNOTATIONS

REGISTRATION OF FOREIGN DOCTORS

NOT long ago we gave an account of the first year's working of the Academic Assistance Council in its task of assisting university teachers and investigators unable to carry on their work in their own country on grounds of religion, political opinion, or race. Assistance was not confined to German exiles, and the resources of this council enabled it to make maintenance grants to 49 scientists or scholars and to place 129 others. It was no part of this council's task to help medical men with foreign qualifications to find openings for practice in this country. It is however well known—and has been the subject of some adverse comment—that the Conjoint Board of Scotland is enabling a number of these foreign doctors to take the final qualifying examination after a short course of study. It was reported to a council meeting of the British Medical Association on June 6th that about 180 foreign doctors are availing themselves of this concession, and the chairman of the B.M.A. council said it was expected that about 150 of them would remain in Great Britain and Ireland, where an attempt would be made to place them in cities where there is a large Jewish element. Of the remainder some, he said, might go to South America, but there was every reason to believe that not a single one of them would find his way to Australia, New Zealand, or South Africa. They themselves had no money, and there was no body which had the funds necessary for the payment of passage money. The practical problem was therefore not that of safeguarding the Dominions and Colonies from inundation, but of dealing with at most 150 medical persons who would be settling in this country during the next 18 months for such period as the Home Office would allow them to stay. The Dominions Committee of the B.M.A. expressed the opinion that it was desirable to increase to three years the period of study in this country required before admission to a final qualifying examination.

THE PRODUCTION OF ARTIFICIAL PYREXIA

WE have recently considered in these columns [1] the thermostatic control of the warm-blooded animal and some of the outcomes of the attempt to evade this control and to produce artificial fever, local or general. It is important to be aware of the nature of the agencies employed. Until recently the term "diathermy" was limited to the production of heat in the human body by the passage of oscillating currents with a frequency of about 1,000,000 a second. These were generated by the discharge of a condenser through a coil of suitable inductance, or in some of the newer machines by causing a thermionic valve to generate oscillations. The mechanism in the latter case is more difficult to understand than in the simple spark machine, but it is analogous in some degree to the action of the balance wheel or pendulum of a clock. In the simplest arrangement, two circuits each containing an inductance and capacity are connected to the appropriate electrodes of the valve, and are at the same time so situated that they are inductively linked with one another. In this state any slight variation in one circuit will produce an enhanced variation in the other, owing to the amplifying properties of the valve. This induces a second impulse back into the first circuit, and under suitable conditions the valve will break into a sustained oscillation which continues as long as power is supplied to the circuit. The frequency of the oscillations produced depends entirely on the electrical constants of the circuits employed, but the intensity of the high-frequency circuit is a function of the size of the valve and its capacity for taking reasonable power without overheating. In recent years there has been considerable investigation of the action of currents of still higher frequency, of the order of 10 million a second. Such currents have been obtained from valve outfits almost exclusively, though one type of spark instrument suitable for local treatment has been made in this country. When such high frequency is in use, the patient is placed between two insulated plate electrodes which are not in contact with the skin, the tissues of the body forming part of the dielectric of a condenser. Smaller plates are used when local treatment is intended. In another form of instrument recently devised, the Inductotherm, the currents are produced in a flexible insulated cable which is wound round the body or part to be treated. Such an arrangement would lead to a different distribution of the induced currents, but there is no essential difference between the two methods. In both cases the observed rise in temperature can be regarded as the result of induced currents of high frequency in the body. Merriman, Holmguest, and Osborne [2] maintain that there is a difference in conductivity of various tissues towards these new currents as compared with diathermy, but it would be premature to deduce this from the results of experiments in which the methods differ so widely in detail. There is some difficulty in finding a suitable term for the description of the new therapeutic agent. In America the word "radiothermy" has been suggested as being the production of heat by currents such as are used in wireless telegraphy. But the term might lead to confusion with radiant heat. There is a tendency to lay emphasis on the presence of electro-magnetic radiation as being the heating agent, which does not seem to be justified by consideration of the machinery used. The fact that the frequencies in question are the same as those used in so-called short-wave wireless has suggested the term "short-wave diathermy." While this may not satisfy everyone, the term is convenient and it emphasises the relationship of the new agent to the original diathermy current.

HÆMATOPORPHYRIA

A RECENT number of *Medicine* (Baltimore) contains a very complete review [3] of this rare but interesting condition, together with an account of two cases which came to autopsy and offered material for the study of the nature of the histological changes in the nervous system. After explaining that hæmatoporphyrin is not actually the pigment involved (for only uroporphyrin and coproporphyrin are found in the urine), the authors distinguish four types of the disease—chronic, congenital, acute toxic, and acute idiopathic. The first two are characterised by the development of certain skin lesions on exposure to light, and the last two by symptoms resembling Landry's paralysis so closely as to suggest the advisability of a careful spectroscopic examination of the urine in all such cases. It is an interesting question, which is not finally settled, whether drugs such as sulphonal can actually produce hæmatoporphyria, or whether they merely act as exciting causes in persons already exhibiting the disease in a latent form. While the chronic types are relatively benign in character, the prognosis in the acute forms is bad. No treatment appears to be of any avail, but calcium is recommended on theoretical grounds. The origin of the pigments is still uncertain. The older theory of a disturbance of hæmoglobin katabolism is questioned by Fischer, whose work makes it extremely probable that neither uroporphyrin nor coproporphyrin can be derived from hæmoglobin. It would appear that they are synthesised from ingested pyrrole compounds, principally by the bone-marrow. This is a process which normally occurs only to a slight extent, but is much more prominent in fœtal life and in certain birds; it probably represents a stage in the synthesis of hæmoglobin. The suggestion is of a reversion to a more primitive level of pigment formation, in fact a kind of atavism. This theory, which implies perhaps the lack of specific enzymes, agrees well with the observation that congenital hæmatoporphyria is usually inherited as a Mendelian recessive.

MENTAL DISORDER ASSOCIATED WITH PREGNANCY

It has generally been believed that the insanities occurring in association with pregnancy have a good prognosis, but clinical studies of any large series of cases are hard to find. Dr. C. B. Bamford has recently analysed[1] the 97 cases admitted into the Rainhill Hospital between 1883 and 1933. He believes that these psychoses only form one-tenth of the insanities associated with reproduction, and he also concludes that in 60 per cent. of his cases some form of mental disability was present before conception. Of the 97 cases, 25 were defectives or epileptics; schizophrenic or manic depressive signs had already manifested themselves in 23 cases before the outbreak of those serious abnormalities for which detention became necessary. The determination of the point at which mental disease actually began was by no means easy, and it is perhaps surprising that 35 per cent. of the patients, including half the epileptics, made a complete recovery. The absence in the series of any evidence of a toxic or exhaustive factor is striking, and it points to one essential difference between gestational and puerperal cases. In the former, constitutional factors and previous signs of faulty stock are to be expected; in the latter it is toxæmic concomitants which are generally easy to find. That a psychopathic inheritance was only recorded in 17 cases may well be due to lack of interest in this matter in the earlier period covered by the review; it would be difficult to believe that unstable heredity was present in less than 20 per cent. of these potential psychopaths. Dr. Bamford notes that confusion was present in 23 of the 34 recovered cases and compares this finding with the absence of recorded exhaustion or intoxication. It seems clear that the altered metabolism of pregnancy precipitates mental disorder in suitably constituted persons as it produces eclampsia in others differently constructed. All the cases were much worse at the time of delivery and most of them only began to improve after the second month. In view of the recovery-rates, Dr. Bamford questions whether premature termination of the pregnancy is advisable. In the Rainhill series it was never attempted. What is of present-day interest is the high percentage of psychopaths among the cases, and the question of limiting fertility naturally arises. Whilst the prognosis appears good it is less so than is commonly taught.

RUNNING AND WALKING

At full speed a champion sprinter attains a velocity of 23½ miles per hour, a performance which compares not unfavourably with the racehorse's 36 miles per hour. It must be conceded, however, that the quadruped maintains this speed over the Derby course of a mile and a half; a runner over the same distance would be capable of an average rate of about 13 miles per hour. The fastest walking recorded, half a mile in three minutes, illustrates the comparative inefficiency of this method of progression. A first-class long distance runner can continue at that rate for over two and a half hours. Nevertheless it is a matter of common experience that walking is suitable for low speeds, and is indeed, up to a certain limit, more suitable than running. But when higher speeds are required, the muscular mechanism of the body is adapted to run. There is a range of speeds at which, mechanically considered, running and walking are equally possible, a range which is fairly strictly limited since really fast walking demands a considerable course of training and a high degree of athletic efficiency. Within such limits it is possible to compare the energy expenditure required in the two methods of progression. F. G. Benedict and H. Murschhauser (1915),[1] Furusawa and others (1924),[2] basing their conclusions upon the oxygen intake during the effort, have demonstrated the greater energy efficiency of running. Recently Ogasawara,[3] working from the department of industrial physiology of the London School of Hygiene, has repeated these investigations in estimating the oxygen requirement—i.e., the excess of oxygen used in exercise and recovery—per minute when walking and running at the same speed.

Ogasawara's subject walked or ran 500 metres whilst carrying a portable Douglas bag in which the expired air was collected during the exercise and the subsequent period of 40 minutes rest. He found that when the rate of progression was substantially the same, the measured oxygen required for walking was approximately 4 per cent. greater at a speed of five miles per hour, increasing to 20 per cent. at six and two-thirds miles per hour. As Ogasawara points out, these comparisons of oxygen requirement per minute for walking and running are not a true comparison of the oxygen used or required per unit muscular movement—namely, per stride. In the case of running, fewer movements are performed than in walking, although the speed of progression and the total distance covered may be the same. Inasmuch as the length of stride in walking is less than that in running, more strides must be taken to approach the speed, and the difference in oxygen requirement appears to be directly related to the number of strides in each case. The vigorous arm swinging movements inherent in walking must be responsible for some increase in oxygen requirement, and attempts have been made to estimate its extent by independent observations. But as in fast walking the swing of the arms across the chest is an essential feature, the isolated study of this movement is without significance in the comparison of walking and running. In running, speed is an expression of length of stride and rapidity of striding, and both are amenable to considerable variation. Investigation of an Olympic games sprint champion showed that 45 strides are taken in the course of 100 yards at the rate of 270 strides per minute. In ordinary easy walking, at the rate of 3½ miles per hour, 110 strides each of a length of 38 inches were found to be taken per minute. The same trained walker when increasing his speed to seven, eight, and finally nine miles per hour found the length of stride to increase to 45 inches, which appears to be the maximum possible in a walker, any increase of speed being obtainable only by increasing the rate of striding, the maximum possible for a comparatively short time being 230 per minute, though rates of 200 to 212 to the minute could be maintained for a considerable period.

With the coöperation of G. P. Crowden and Adolphe Abrahams, Ogasawara has extended the range of his observations to a few similar investigations of running and walking 440 yards at the rate of nine miles an hour. This would appear to be the highest speed physically possible in the case of walking, and practically possible in the case of running, when the mechanical difficulty of carrying a Douglas bag is considered, not to mention the handicap of wearing a nose clip. At this speed the walking strides were at the rate of 200 per minute, the running at the rate of 175 per minute. The effort involved in the walk demanded 23½ per cent. more oxygen in exercise and recovery. Subjectively the exhaustion in walking is enormously greater, as might be expected from the effort required to maintain contraction of the muscles of the leg at this speed.

IMMUNISATION OF CATTLE AGAINST TUBERCULOSIS

From the Sir William Dunn School of Pathology, Oxford, comes a report by Prof. G. Dreyer, Dr. R. L. Vollum, and Dr. H. H. Ammitzböll on the results of a nine years' field experiment on the immunisation of cattle against tuberculosis.[1] The test was carried out at Söllestedgaard Manor, an estate on the Island of Lolland in Denmark on a herd of red Danish cows which was known to have been infected with tuberculosis since about 1885. By the time the experiment was commenced in 1924 the herd had been greatly reduced by the disease and all the milch cows and 75 per cent. of the bulls, heifers, and calves were infected. From November to May the cattle were kept stabled and in the summer tethered in the fields so that ample opportunity for infection existed. The defatted or "diaplyte," vaccine of dead tubercle bacilli, introduced by Dreyer in 1923, was used throughout. A preliminary course of four intravenous injections was given as soon as practicable after the birth of the calf with subsequent injections in autumn and spring. The first dose was 1·5 c.cm. of an emulsion containing 5 mg. bacillary substance per c.cm., increased to 10 c.cm. or more. Anaphylactic shock occasionally followed the third or fourth injection. Ninety per cent. of the animals in the herd were tuberculous at the beginning of the experiment, and although the immunised animals were allowed to mix freely with the infected stock, only two cases of clinical tuberculosis occurred among the 281 animals which had been immunised from an early age. Out of 55 animals examined post mortem, six had tuberculous lesions, in three instances the lesions being calcified. Taking these figures as a fair sample of the whole herd the records of the experiment indicate that only 10·9 per cent. of the vaccinated animals became infected. The writers consider that the procedure adopted in this experiment could be applied to any herd of cattle without undue inconvenience or interference with the commercial management of the herd.

THE TALE OF ST. THOMAS'S HOSPITAL

The period (1600–1800) in the history of St. Thomas's Hospital, covered by the second volume[1] of Prof. Parsons's record of its activities, is less picturesque than that described in the previous volume, but is still full of interest. Throughout this time the hospital continued on its previous site in Southwark, but now procedure had become more standardised. Since it was recognised as one of the great medical institutions in the country competition for election to the staff was already keen; candidates did not scruple to obtain letters of recommendation from King James I. or Charles I., and later from Oliver Cromwell, Fairfax, Speaker Lenthall, and others. In the year 1639 both the matron and the hospitaller were imprisoned for debt. Through the efforts of a committee of the governors the matron was liberated, but although the hospitaller was eventually able to return, the governors did not reinstate him. The trouble in both cases appears to have been due chiefly to the decrease in the purchasing power of money between 1620 and 1636, particularly in regard to food, and as the matron for most of this time was only allowed 2*s*. 4*d*. a week for that purpose it is small wonder that she became insolvent. The duties of the matron appear to have been onerous, and in 1642 they must have been increased by the following order made by the governors. "She is to examine all women patients suspected of being with child, monthly: and if she neglect to do so she is to provide for the child born in the hospitall." During the Civil war the sympathies of the governors appear to have been on the side of the Parliament. In August, 1643, the three surgeons of St. Thomas's asked for a gratuity for dressing many soldiers of the parliamentary army and were awarded £10 apiece. One of the surgeons however, Molins, went off to tend the Royalist wounded: he was captured when Arundel Castle was taken and displaced from the staff by order of parliament, but reinstated at the Restoration. The most distinguished physician to St. Thomas's at this time was Sir Francis Prujean, who was recommended by the great Harvey as the fittest president of the College of Physicians, when Harvey, although elected, excused himself from that honour on account of his age and infirmities. Prujean seems to have left nothing written whereby his medical capacity can be judged. In 1647 Dr. Thomas Wharton, the discoverer of Wharton's duct, was elected physician. He acquired a large practice in London; and it is pleasing to record that during the Great Plague of 1665 he remained at his post, Charles II. having specially asked him to take charge of the plague-stricken soldiers who were brought to St. Thomas's. It would appear that the only reward he got was an augmentation to his arms for which he had to pay a fee of £10 to the Heralds College. One of the surgeons to St. Thomas's who was also lithotomist to St. Bartholomew's successfully operated on Samuel Pepys for stone. The progress made between 1600 and 1700 is thus summarised by Prof. Parsons.

> "Typhus, enteric, and scarlatina were now recognised among the fevers, fresh air in sick rooms and wards was

[1] The History of St. Thomas's Hospital. By F. G. Parsons, D.Sc., F.R.C.S., F.S.A. Vol. II. London: Methuen and Co., Ltd. Pp. 281. 10*s*. 6*d*.

understood, steel was prescribed for chlorosis, and Peruvian bark for ague, while limbs were now amputated by the flap operation. Syphilis was treated by salivation, and lithotomy was a special branch of surgery. We must also note that leprosy, sweating sickness, and plague were things of the past."

Between 1693 and 1720 no less a sum than £37,769 was subscribed by the public and early in the eighteenth century much rebuilding was undertaken. During this century the staff included the great names of Mead and Cheselden. Sir Robert Clayton, whose statue by Grinling Gibbons is still in the possession of St. Thomas's, was one of the chief contributors, and Dr. Parsons remarks "that until the present history was undertaken nobody seems to have realised that such an important piece of Gibbons's work was owned by them." In 1707 the name of Thomas Guy, Esq., appears for the first time among the governors. It is interesting to learn that before 1655 all the governors were called Mister, after that the Esquires were carefully distinguished until in 1815 they all became Esquires. Guy was a great benefactor to St. Thomas's and defrayed the cost of a block of three wards costing £1100 and endowed them with £100 a year during his life. In 1721 he founded a hospital for incurables within the close of St. Thomas's. It is said that this scheme was suggested by Mead, with the idea that the new hospital should act as an infirmary to supply St. Thomas's with chronic cases to treat, and thus provide the staff there with interesting patients. Prof. Parsons, takes the view that Guy probably intended that the poor incurables should have a place where they could be cared for when the rules of the hospital required their discharge. As he points out, had Guy intended to found a new general hospital he would never have chosen a place so close to St. Thomas's. 'Guy wisely left a perfectly free hand to his executors and trustees to modify the hospital that he founded in the way that was afterwards effected. The manner in which the two hospitals later became separated belongs to the history of the next century and no doubt will find a place in the next volume.

VON GIERKE'S DISEASE

FIVE years ago E. von Gierke described a disturbance of carbohydrate metabolism characterised by great accumulation of glycogen in the liver and kidneys. He regarded the condition (which he observed in two children) as due to inability to mobilise glycogen owing to a deficiency of glycogenase. Since then a number of similar cases have been investigated during life, recent reports including those of van Creveld,[1] Unshelm,[2] Rauh and others. The most characteristic features appear to be great enlargement of the liver (which is uniform, smooth, non-tender, and unassociated with splenomegaly), ketonuria, and a low resting blood-sugar. The inability to mobilise glycogen readily is shown by a very slow or inadequate rise of blood-sugar after the injection of adrenaline, whilst the dextrose-tolerance curve is sometimes abnormal. As indicated by von Gierke's original cases, the retention of glycogen may affect organs other than the liver, and van Creveld has pointed out its importance in causing congenital hypertrophy of the heart and pylorus. The same author has studied in two cases the glycogen content of the blood by an original and simplified method, and has constantly obtained high values in the fasting state. He provisionally considers this elevation of blood glycogen to be of some significance in the diagnosis, and further regards the glycogen in the blood as being abnormal in that it was split with difficulty. Although the number of examples of this condition which have been recorded as v. Gierke's disease is still small, there is little doubt that it will prove commoner than is generally supposed. In this country isolated cases have been described by Bellingham Smith and O'Flynn,[3] and Worster-Drought,[4] and R. W. B. Ellis [5] has reported the condition in two sisters in whom it was associated with a marked degree of infantilism. He suggests that the infantilism—which is a not infrequent finding in the older cases—is due to consistent slight carbohydrate starvation of the tissues by reason of the low resting blood-sugar, and that it represents the reverse of the gigantism sometimes seen in the infants of women with early or "pre-diabetes" whose blood-sugar is slightly though consistently raised.

VITAMIN-A DEFICIENCY AND THE TEETH

THE rôle of vitamin A as an essential element in the diet for normal functioning of the nervous system was first established by Prof. E. Mellanby. Mrs. May Mellanby then showed that when this vitamin was deficient the epithelial and sub-epithelial gingival tissues in dogs became hyperplastic and readily infected. Taken in conjunction with Mrs. Mellanby's studies on the effect of vitamin-D deficiency on the teeth of experimental animals, this suggested that just as vitamin D might be the main factor in bringing about an immunity to dental caries, so vitamin A might be equally essential in preserving the integrity of the gingival tissues and so conferring immunity to pyorrhœa. Mrs. Mellanby in conjunction with J. D. King has now published a paper [6] describing a series of experiments on dogs, rats, and rabbits to illustrate the effect of a diet deficient in vitamin A on the nerve-supply of the teeth. The animals were given a basal diet adequate in regard to vitamin D and other constituents and to this was added vitamin A in such forms as cabbage, carotene, and cod-liver oil. Controls in each group received the same basal diet but with the substitution of heated alfalfa or heated olive oil for the vitamin A element. The duration of the experiments varied from 25 days up to six months in the different animals used. Immediately after the animals were killed pieces of the maxillary and mandibular nerves just peripheral to the Gasserian ganglion were taken and prepared by the Marchi and other methods. It was found that in all the animals given a diet rich in vitamin A the gums were normal, both clinically and microscopically, while sections of the nerves showed no signs of degeneration. Among the controls gingivitis was present in all three classes of animals. Microscopically the periodontal tissues showed hyperplasia of the gingival epithelium. Sections of the nerves revealed degeneration in varying degrees, while those of the Gasserian ganglion showed chromatolysis of Nissl's granules in many cells. The illustrations contrasting the appearance of the nerves in the two sets of animals are convincing. It would appear that two distinct lesions may result from a diet deficient in vitamin A; an infective lesion of the soft gingival tissues and a degeneration of the sensory nerves supplying them. That these two changes are connected seems probable since there is a good deal of evidence that the integrity of tissues depends on trophic influences. Attempts are now in progress to determine which of the changes comes first, for establishment of the fact that degeneration of the nerves always preceded the changes in the gingival tissues would support the idea of a causal relationship. The authors suggest that the lack of neurotrophic control induced by a deficiency of vitamin A may be partly responsible for the incidence of pyorrhœa and other gingival diseases. It would be unwise at this stage to emphasise too strongly the analogy between effects produced experimentally on animals and the diseases of the gums common among mankind. Clinical observation in many parts of the world has shown that pyorrhœa is prevalent among races showing a high immunity to caries, and this applies also to individuals. It is, of course, possible that a diet might be adequate in vitamin D and poor in vitamin A and vice versa, but their distribution in nature makes this unlikely. The apparent absence of any local factor in many cases of pyorrhœa, especially in young persons, suggests strongly that some general factor is primarily responsible for the incidence of the disease and thus lends some support to the view that nutrition may play a part in the ætiology of pyorrhœa. It would be interesting to test the hypothesis by experiments on man comparable to those undertaken by Mrs. Mellanby in Birmingham and Sheffield on vitamin-D deficiency and by Boyd and Drain in America. Such tests would be more difficult to plan in so far as the main incidence of dental caries is in early life and can be investigated in children living under institutional conditions; whereas the incidence of pyorrhœa is greatest in adult life where suitable conditions for large scale feeding experiments, in this country at least, are not easy to come by.

"LIVING DANGEROUSLY"

To put medicine on the boards of the theatre is attended with fundamental difficulties similar to those which await the writer who uses medicine in the development of a novel. In each case medicine offers two invitations, one on the clinical side and the other on the administrative or professional side, and in both the opportunities for the layman to go wrong are numerous, for neither the Medical Acts nor therapeutic treatises are simple of comprehension or open to popular condensation. The author, dramatist, or novelist, when medicine is the theme, should not therefore be blamed for inaccurate presentation of details, which may fairly on occasion be subordinated to the necessities of the story. But that way danger lies; it is not easy for the layman to decide whether what is apparently a detail may not be a fundamental principle. However, in the medical play, "Living Dangerously," which is meeting with interested attention at the Strand Theatre, Mr. Reginald Simpson and Mr. Frank Gregory have been able to avoid all serious misrepresentation and also to furnish arguments for a medical reform which the public at any rate considers necessary. True, no medical firm of the constitution described could be found in Wimpole-street, and no procedure of the exact sort depicted could take place in Hallam-street; but the exigencies of the narrative have entailed the inaccuracies, while the balance of criticism is preserved, for, if the medical villain is a disgusting fellow, as played by Mr. Martin Walker, the brow-beating barrister, presented by Mr. Eric Stanley, would be a greater danger to wholesome society. The first two acts are taken up with the description of an unprofessional traffic in drugs, and a trial before the General Medical Council, which has its real origin in that traffic, but the issues involved are those of an accusation of adultery with a patient. In the third act we move from medical Marylebone to the wealthiest street in New York City, and the action becomes frankly melodramatic. The doctor who has been wrongfully removed from the British Register is described as having had no difficulty in taking the necessary degrees and in rising promptly to a high professional position in America. That we submit to be very unlikely, but the improbability should irritate no one because of the brisk happenings which follow, and which are concluded with a particularly neat application of rough justice. The essential message of an interesting play is that there should be some recognised form of appeal from the decisions of the General Medical Council, and Mr. Godfrey Tearle, in the character of the unjustly expelled doctor, gives by his admirable acting a force to the plea. But in real life the false testimony, neatly supplied by Miss Helen Goss, in the rôle of the perfect female dog, would not have had the force attributed to it; and Miss Carol Goodman, the pathetic victim of malignity, when giving her evidence would have been protected from gross insult.

A PIONEER OF AMBULANCE

Dr. Arthur William James, who lost his life on June 18th in a motoring accident, had done more than anyone living to mitigate the terror of accident on the road. It is just thirty years ago since Dr. James enrolled some 1100 medical men in London, about one in five of the total number, to form the Metropolitan Street Ambulance Association. Already at that time there were 15,000 severe casualties each year in London streets and there was no organisation or equipment for the rapid transport of injured persons to home or hospital. In that year pressure was brought upon the London County Council by the Presidents of the Royal Colleges and others to induce the Council to graft upon its fire brigade an efficient ambulance service. It was, it seems, Sir William Church who first saw the practical advantage of combining these two services; Dr. James, who was not only founder but hon. secretary of the Ambulance Association, was able effectively to point out the ease with which the fire brigade service could deal with casualties, if provided with the men, horses, and ambulances, without interfering with their primary duties. The desired change followed quickly upon the combined stimulus, and shortly after that date London took steps to redeem the reproach of being behind Liverpool and many continental towns in the provision of help for those unable to help themselves in case of sudden illness or accident. In this achievement the name of Arthur James will be gratefully remembered.

A RECEPTION will be held at the Royal College of Surgeons of England, Lincoln's Inn-fields, on Wednesday, July 11th. A series of interesting demonstrations will be provided by prominent institutions and medical schools directed to the illustration of recent advances in medical science, special attention being given to experimental researches bearing on the nature and treatment of cancer.

ON Wednesday, June 27th, at 5 P.M., at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W., Dr. William Allen Pusey, of Chicago, will deliver the Prosser White oration to the St. John's Hospital Dermatological Society. The subject of the lecture will be Disease, Gadfly of the Mind, especially the Stimulus of Disease in the Development of the Mind. The meeting is open to all medical practitioners.

PROGNOSIS

A Series of Signed Articles contributed by invitation

VII.—PROGNOSIS OF STAPHYLOCOCCAL INFECTIONS OF THE SKIN

THE structure of the skin renders it highly resistant to both physical agents and bacteria, but like most suits of armour it has its weakness; in this instance it is the depression known as the hair follicle. As the staphylococcus finds this site most suitable for multiplication it is not surprising that this organism is responsible for a considerable proportion of the infections of the skin. It may be assumed that most people are frequently contaminated by the organism. Yet mere contact is not necessarily followed by a pathological lesion—the staphylococcus may enter a follicle and remain alive for days, but unless there is added trauma to the skin and the resistance is consequently lowered, the cocci are unable to multiply and do harm. The experiments of Norton and Novg[1] appear to show that the skin has no direct germicidal power. These workers applied *B. prodigiosus* to the skin and found that the organisms diminished rapidly in numbers, particularly during the first ten minutes. Similar results were obtained when cultures of this organism were placed on inert material such as paper or leather. The same authors made the interesting observation that the rate of disappearance in each instance appeared to be governed almost directly by the amount of moisture present, and clinical experience with staphylococcal infections appears to support these findings, for drying the skin is undoubtedly one of the most efficient methods of preventing the spread of the lesions.

It is noteworthy that some persons carry foci of staphylococcal infections on the skin without intermission for 20 or more years, and yet contacts living in intimate relationship with them may remain absolutely free.

A fact not generally appreciated is the relative immunity of the female. An analysis of 163 cases of recurrent boils attending the skin department of the Royal Infirmary, Sheffield, showed that of this number only 18 per cent. were female. Even in deeper infections such as osteomyelitis, the incidence is approximately three males to one female. It is questionable whether the difference in environment and exposure to injury of the sexes can be entirely responsible for this variance. It appears as if the female skin offers a less suitable habitat for the growth of the bacteria.

It has already been stated that the staphylococci find the follicle the locus minoris resistentiæ. If the resistance of the individual is high, the activity of the organism may be restricted to the mouth of the follicle producing the condition known as

SUPERFICIAL PUSTULAR FOLLICULITIS

an example of which condition is found in the minute pustules found on the skin around infected wounds and boils. Similar pustules are also met with frequently on the anterior surface of the thighs in workers engaged in industries involving the use of oil or tar. Another situation is on the scalp of children, usually as a sequence to an infection of pediculosis capitis or impetigo.

On the glabrous skin the pustules run a benign course, and even without treatment there is a tendency for them to dry up and for the tiny crust to be shed. Occasionally a few of the pustules may coalesce, forming small superficial ulcers; in this event the frequent application of wet dressings of ½ per cent. silver nitrate solution will usually promote rapid healing. When the affection involves the thicker hair of the scalp or pubis the prognosis is by no means so favourable, for successive reinfection of the follicles is apt to occur, accompanied by swelling of the neighbouring lymphatic glands. The complaint may continue for weeks or even months, unless suitable treatment is carried out with careful attention to details. The hair should be clipped short, crusts removed, pustules opened, and the area painted with applications such as 1 per cent. solution of brilliant green, or 2 per cent. sol. silver nitrate. Should X ray therapy be available it will be found to expedite healing.

THE BOIL OR FURUNCLE

If the conditions are favourable the staphylococci, in addition to multiplying at the orifice, gain access to the depth of the follicle along the hair shaft and produce the boil, the lesion so frequently met with in youth. The prognosis of the single boil is excellent, the average course being about two weeks, but during that brief period the sufferer usually unwittingly promotes the growth of staphylococci in the neighbouring follicles by the warmth and moisture of applied poultices and fomentations. Other boils follow, and soon follicles near and far are contaminated with the same organisms which only wait favourable conditions for their growth. If looked for, contributory causes will be found in the skin in a large proportion of the cases—for example, scabies, seborrhœa, and lastly, but important, pruritus ani. The trauma from any one of these complaints may suffice to lower the resistance of the skin and may prolong the malady of recurrent boils indefinitely unless removed, or until the patient by a process of continued self-inoculation establishes sufficient resistance to protect himself against the staphylococcus.

In addition, the possibility of general predisposing causes must be considered; for instance, debility following serious systemic disorder will naturally influence the course of the malady. The relationship between recurrent boils and diabetes has received considerable attention. In actual practice the percentage of cases of recurrent boils associated with glycosuria is very small. Fortunately sufferers from furunculosis are usually unaware of the serious complications which may assail them during the course of their complaint, but the association between the infections of the skin and the conveyance by the blood stream to the deeper areas is now generally recognised, and surgeons repeatedly obtain a history of boils preceding such diseases as perirenal abscess, prostatic abscess, and osteomyelitis. The most dramatic and serious complication, however, is the extension of the infection from the boil on the face and neck to the cerebral veins, a disaster nearly always terminating fatally. Therefore the presence of a boil on the face, particularly in the neighbourhood of the upper lip, is a contingency which necessitates a guarded prognosis, but it should not be unduly pessimistic. Happily, [illegible] the face, most boils run a simple course, in fact heal rapidly; nevertheless it is a wise precaution to detain the patient in bed until the core has been discharged.

The tendency for a boil to be followed by a succession of others at short intervals is so constant that the prognosis of the malady largely turns on the efficiency of the prophylactic measures. The patient naturally seeks relief from the pain and admittedly there is nothing so efficacious for the purpose as moist heat in the form of a poultice or fomentation. Nevertheless, it cannot be too strongly emphasised that it is also a common cause of the recurrence—the purulent discharge soaks into the dressings and cocci are spread to the neighbouring follicles where they are encouraged to multiply under the optimum conditions of heat and moisture. Pads soaked in methylated spirit or a mixture of sulphate of magnesia and glycerin will be found a useful substitute for fomentations.

---

[1] Norton and Novg: Amer. Jour. Pub. Health, 1931, xxi., 117.

Attempts have been made to abort boils in their early stages before the infection travels down the follicles, but in my experience these seldom succeed. Although a number of persons appear to have a low resistance against the *Staphylococcus aureus*, it can be stated definitely that in the majority of instances the prognosis is largely governed by the treatment adopted. Contributory causes, either general or local, should be sought for and, when possible, removed, and every effort should be made to prevent spread from the initial lesion. Innumerable therapeutic remedies have been extolled and mostly, I fear, abandoned. It is impossible to discuss even the most popular, but many years of critical trial justifies me in advocating intramuscular injection of colloidal manganese as a means towards cutting short this painful malady.

Strictly speaking, the pathology of the axillary abscess differs from that of the boil—the primary infection being through the sweat ducts; but the ætiology and course is similar, except that the axillary abscess is quite often absorbed without discharging externally.

THE CARBUNCLE

Although a follicular infection with the *Staphylococcus aureus* is the initial lesion of both the boil and carbuncle, in the latter either the terrain is more favourable or the virulence of the organism is greater. The toxin from the rapidly multiplying cocci produces a necrosis which extends and involves the neighbouring follicles. A carbuncle must be considered a more serious lesion than a boil; the duration ranging from four to six weeks. It is accompanied by more pain, often rigors and malaise. In the young or middle-aged the outlook is favourable, excepting the fact that as in boils, other follicular infections may follow; but in debilitated old people the tissue necrosis may assume vast proportions and the absorption may cause delirium, exhaustion, and sometimes death. In favourable sites, when the necrosis is not too extensive, total excision may be practised with advantage, in order to reduce the length of the healing time, and also as a measure to avoid the contamination of the follicles.

SYCOSIS

The term is usually applied to a follicular eruption of the beard and moustache, but similar lesions of the follicles may be found in other areas where hair is present. The chronicity is due to a succession of small abscesses which discharge into the follicle. The epidermis appears to be unable to establish an immunity against the staphylococcus; thus healing of the small abscess cavity is incomplete and a focus remains. Blepharitis, a [illegible] r infection of the lid margin, often [illegible]recedes t[illegible] of the beard, [illegible] by the tears for the cocc[illegible] [illegible] to t[illegible] The chroni- [illegible] to the nose, [illegible] is [illegible] when once [illegible] of th[illegible] [illegible] [illegible], and [illegible]lished [illegible]

the disease may persist for an indefinite number of years. It may be confined to the beard for a long period, and then the hairy regions, such as the eyebrows, scalp, axillæ, and pubis, may be invaded. In spite of the fact that the rest of the skin must be heavily infected with the same cocci, it is noteworthy that boils and other deep lesions are absent. Although there is no tendency to spontaneous recovery a satisfactory termination may usually be anticipated providing the infection is in a relatively early stage and the patient gives his whole-hearted coöperation in the treatment. As the complaint is most commonly met with in the industrial population, it is likely that adequate and carefully selected diet, combined with good hygienic conditions, would be of help. As a local application there is no remedy more efficacious than the following paint: brilliant green, 1 per cent.; methylated spirit and distilled water, equal parts; particularly when combined with suitable X ray therapy.

RUPERT HALLAM, M.D.,
Lecturer on Diseases of the Skin, the University of Sheffield.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt. J. C. Gent to be Surg. Lt.-Comdr.

The following appointments are notified:—

Surg. Lt.-Comdr. G. D. J. Ball to *Pembroke*, for Chatham Barracks.

Surg. Lts. W. B. Taylor to *Grimsby*, and H. A. Clarke and H. E. B. Curjel to *President*, for Medical Dept., Admiralty.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lts. to be Surg. Lt.-Comdrs.: A. L. Gunn and R. H. Enoch.

ROYAL ARMY MEDICAL CORPS

Lt. G. L. McLeod to be Capt.

TERRITORIAL ARMY

Capt. T. L. Clark to be Maj.

Lt. J. D. A. Gray, from Gen. List, T.A., to be Lt.

Lts. N. Moulson and H. G. Wimbush to be Capts.

W. P. Purvis (late Offr. Cadet, Blundell's Sch. Contgt., Jun. Div., O.T.C.), T. N. Rudd, and T. McK. Robb (late Offr. Cadet, Taunton Sch. Contgt., Jun. Div., O.T.C.) to be Lts.

Supernumerary for service with O.T.C.: Capt. J. Whillis (Empld. Durham Univ. Contgt., Sen. Div., O.T.C.) to be Maj.

TERRITORIAL ARMY RESERVE OF OFFICERS

W. N. Lycett to be Lt.

SHORT SERVICE COMMISSIONS IN THE R.A.M.C.

The following candidates who presented themselves for short service commissions, have been granted commissions as lieutenants on probation in the Royal Army Medical Corps: W. M. E. Anderson, M.B., B.Ch., and H. B. Wright, M.B., B.Ch., Trin. Col., Dublin; J. Boyle, L.R.C.P., St. Mary's Hospital; R. H. Foster, B.Ch. Camb., Univ. Col. Hospital; J. S. Ruddell, M.B., B.Ch., Trin. Col., Dublin; A. G. D. Whyte, M.B., B.Ch., Aberd. Univ.; A. L. Pennefather, M.B., B.Ch. and C. G. O'Driscoll, M.B., B.Ch., Trin. Col., Dublin; D. T. Swift, M.B., Ch.B., Otago Univ.; F. E. Buckland, M.R.C.S., Oxford Univ.; A. MacLennan, M.B., Ch.B., Aberd. Univ.; J. H. J. Crosse, M.R.C.S., St. Bartholomew's Hospital; J. Morgan, M.B., Ch.B., Liverp. Univ.; R. A. Stephen, M.D., Aberd. Univ.; E. H. P. Lassen, M.R.C.S., King's College Hospital; R. S. Vine, M.R.C.S., Guy's Hospital; I. Buchanan, M.B., Ch.B., Edin. Univ.; J. E. Jameson, M.R.C.S., St. Thomas's Hospital; M. W. Allen, M.R.C.S., Middlesex Hospital; W. T. Bermingham, M.B., B.Ch., Trin. Col., Dublin; K. H. Clark, M.B., B.Ch., St. Mary's Hospital; M. J. Horgan, M.B., B.Ch. Trin. Col., Dublin. Seven of these officers have been seconded for the purpose of completing appointments in civil hospitals.

SPECIAL ARTICLES

VOLUNTARY HOSPITALS CONFERENCE

(Concluded from p. 1311)

Out-patient Departments

Sir ROBERT BOLAM, opening the discussion following Lord Onslow's paper on out-patient departments, which we summarised last week, said that delay and waiting were not confined to the work of doctors and dentists. He thought a short and popular account of the work of Lord Onslow's committee would be of great educational value. The out-patient departments, generally speaking, were so overcrowded that specialists working therein were not used to the best advantage, patients had to wait, and coördination between general practitioner and specialist services was not properly developed. The only remedy was educational propaganda. Much might be borrowed from the experience of the world of commerce. Some time and much exasperation might be saved by consideration of architectural features and the use of directional signs. Was it too much to hope that anxious patients might meet a courteous usher, with sufficient messengers to serve as guides? The day was over for the slogans "Ever-open door." "No one turned away"; they caused the mistaken impression that the hospital was available for all kinds of service. The time had come to teach the people what services were available in hospitals and how they differed from the services obtained from the general practitioner. It was uneconomical to use the consultant as a sifting agent; that was the work of the general practitioner. There ought not to be any patients who found difficulty in getting a doctor's letter; the percentage of doctors who resented referring a patient to a hospital was negligible. The public must educate the doctors to give letters to hospitals without difficulty. Patience and forbearance on all sides were necessary. The problem could not be dealt with solely by conferences and reports; the essential conservatism of the people must be remembered. The hospital-going habits of the nation would not be changed in five minutes.

Mr. ST. JOHN WOOD (Northampton) and Dr. E. BARNES (Manchester) described successful appointments systems in their hospitals, which had overcome all the difficulties mentioned. Secretarial assistance was provided but dictaphones had not proved satisfactory.

Mr. A. H. LEANEY (Birmingham) emphasised that the out-patient was more important than the in-patient department because it dealt with the early stages of disease. It must not be rushed. Mr. F. CHORLEY (Devon) lamented the belief of many patients that the earlier they arrived the faster they would be cured.

Sir HENRY BRACKENBURY observed that some hospitals had already converted their out-patient departments to purely consultative work. One of the great evils of the past was the divorce between hospital and private practitioner work. The young resident medical officer somehow got it into his head that the doctor practising outside was not worth considering. It was of the utmost importance that the man doing the domiciliary work should be regarded as an integral and important part of the patient's treatment, both before and after hospitalisation. The discharged patient should be referred to a doctor—and not primarily to the district nurse.

At the discussion on the

Function of the Cottage Hospital

Lord HORDER, from the chair, mentioned the difficulty of defining this important unit of the voluntary system. The cottage hospital gave undoubted benefits to the patient, the doctor, and the community. It was an excellent institution for first-aid—medical as well as surgical. The proximity of friends was a very desirable and important factor in the care of the sick, and the quiet and fresh air of the cottage hospital were of great therapeutic value. Nevertheless the subject urgently needed discussion. Some well-equipped cottage hospitals were empty; others were overcrowded.

Mr. W. M. GOODENOUGH (hon. treasurer, Radcliffe Infirmary, Oxford) in the opening paper expressed appreciation of the work done by cottage hospitals, and recognised the great variation in local conditions. He regarded these hospitals as units in a hospital area, by which he meant one served by a general hospital having a number of cottage hospitals connected with it. Coördination was of increasing importance. He defined a cottage hospital as one in which specialists were not regularly and easily available; there were no resident medical officers or highly specialised equipment, and the staff consisted of local general practitioners. Cottage hospitals were beginning to deal with a certain amount of major work; this was an undesirable development, because every case might produce complications demanding the immediate attendance of a specialist, a resident doctor, or specialised equipment; and transport at this stage could not be good for the patient. Many cottage hospitals now had more beds than they could use and often exercised too little economy. The over-development of cottage hospitals had diverted funds from the key hospitals. The cottage hospital should be limited to the kind of case that could be adequately dealt with by a skilled nurse with the occasional assistance of the local practitioner, and the average cost should not exceed two guineas per week per patient. Another important function of the cottage hospital was to provide convalescent accommodation in the country, provided there was a separate ward for acutely ill patients. As residential centres for district nurses, cottage hospitals might in future prove very valuable. District nurses at present worked as isolated groups under very difficult and varying conditions. In a hospital they could be housed comfortably and economically; motor transport could be provided for them; their more serious cases could be removed to the hospital, and their standard of work would be more uniform than it was at present. The idea should, however, be approached with a good deal of caution. One of the most valuable features of the district nurse was her close and intimate contact with the village people, with whom she lived as one of themselves. Many valuable nurses would object to residence in a nurses' home.

The cottage hospital was essential to the general practitioner, and its connexion with his work was intimate and obvious. The qualities upon which the cottage hospital system had been built were those of local loyalties and enthusiasm, and these qualities must be fostered in every possible way. Coördination might be achieved by the establishment of advisory committees representative of all the hospitals in a district; these organisations would not over-ride local views or local independence but would make recommendations for the allocation of funds and space.

The cottage hospital was obviously not suitable for the training of nurses, and to staff the cottage hospital with trained nurses only would cost more than most of them were now spending on their nursing staff. A suggestion worthy of consideration was that they might combine with central hospitals for interchange of staff—the trained nurses gaining experience of housekeeping and other work in a cottage hospital, and girls too young for general hospital training being kept for a period at the cottage hospital.

Dr. C. E. S. Flemming suggested the name "district hospitals" for these institutions. They were essential for the completion of the hospital service of the country, and to enable the general practitioner to give of his best, which was now of a very high order. It might be dangerous to interfere with the development of such a growing department by rigid rules. They were essentially general practitioner hospitals, and ought to remain so. Coöperation with larger hospitals should include both work and maintenance; each district must provide its own funds, but charges should be standardised.

Mr. G. H. J. Dutton (Skegness) pointed out the usefulness of regional committees in motor accident cases. Mr. P. J. Neate (Cancer Hospital, Fulham) urged closer collaboration between great general and specialist hospitals and the cottage hospital for the purpose of ensuring early and accurate diagnosis. Mr. A. Fouchard (Mexborough) disagreed with the reader of the paper. His cottage hospital had much up-to-date equipment, two resident medical officers, and a nurses' hostel, supplied largely by miners' welfare funds. He did not think convalescents or district nurses should be accommodated in the cottage hospital. Mr. Goodenough's suggestions would not be welcome in South Yorkshire. He urged that local executives should be left to deal with local needs as they saw them. Mr. Chorley quoted figures to show that there were many vacant beds for convalescents, but unfortunately cottage hospitals did not care to take back cases that had been sent on to key hospitals. Mr. Goodenough replied to a question: do most cottage hospitals treat members of their contributory schemes as subscribers and give them a voice in management? He said that he thought they usually did, by means of elected representatives. Mr. J. A. Ritchie (Hornsey) recommended allowing every doctor in the district to use the hospital, and providing for visiting specialists the same efficiency and equipment that they found in their own hospitals.

Lord Armstrong (Newcastle) said that in Northumberland some patients preferred district nurses, who lived in their own houses, and others preferred village nurses, who lived in a community. The problem of motor accidents greatly concerned cottage hospitals.

A paper on

The Hospital and its Architect

was read by Mr. E. Stanley Hall, F.R.I.B.A. He said that two points were of vital concern in the economy of hospital planning: the architect should be called in at the earliest possible moment and he should have a very small and very sympathetic building committee. The architect was seldom called in until the site had been selected, yet many points of contour, subsoil drainage, sewage disposal, approaches, water and other supplies, aspect and prospect would affect both planning and cost. The best way of coördinating the various interests was to have a technical committee of physicians and surgeons to report to a very small lay committee directly responsible to the board. The technical committee would decide what they wanted, after frequent consultation with the architect, and the lay committee would decide what could be afforded. It was difficult to make lay members understand how vitally important was the work of planning in the early stages. The growth of hospitals had been largely haphazard. The programme to be settled included the total number of beds and their allocation, the nursing unit, the operating theatre unit, the casualty and out-patient department, the staff home, administration block, boiler house, laundries, and pathological department.

Subject to statistical requirements, the hospital should be as large as possible, because expensive plant such as X ray, electrical, and sterilising apparatus need not cost twice as much for twice the number of beds. There should always be allowance for future expansion. It was more economical to have one large hospital than two small ones. The architect must know the number of patients per nursing unit before he could plan the wards. The present tendency was to decrease the size of the wards, but this increased the cost of nursing, and hospital authorities had to hold the balance. The necessary ancillary rooms for each unit must also be decided on at an early stage. Some hospitals preferred to have separate theatres on different floors; this was less economical than grouping the theatres into one unit. Twin theatres could often share a sterilising plant, thus effecting an important economy. Considerable ingenuity was required in arranging for students in the theatres of teaching hospitals. A valuable but expensive device was the French Scialiscope, which threw a reflection of the operation upon a screen in an adjoining room. Any previous experience the architect might have of casualty and out-patient departments would only be enough to warn him of the necessity for obtaining the most detailed information of the way in which the one in question was to be worked. There was infinite divergence in practice. An architect could not fail to be struck by the uneconomical occupation of out-patient consulting-rooms and theatres. He would plan a most elaborate suite for eye cases and be told that it would be in use once or perhaps twice a week. The needs of various specialists must be weighed very carefully in planning the out-patient department.

The architect would know that every nurse and maid should have a separate bedroom, generally with fixed basins and fitted wardrobes—requirements which increased the capital costs but saved running expense. Staff dining rooms and kitchens had an important bearing on the whole design. The kind of fuel to be used and the kind of heating apparatus required must be decided early. The advent of the Grid had brought electric energy within the reach of most sites, but gas had many attractions if the price was right and quality and pressure guaranteed. Laundries should be moved away from the hospital if possible, and a common laundry for all the hospitals of one area would be an economy and an advantage.

The first problem for the architect when he had collected the rough parts of this jig-saw puzzle was to consider whether the hospital was to extend horizontally or vertically. Separate units of two or more storeys minimised the risk of fire, and were more elastic in plan and less institutional in appearance. High buildings demanded lifts, which were expensive to run and maintain; the upper floors were healthiest and should be used for theatres and as many patients as possible, and not for kitchens and dining rooms. Flat roofs should always be available for staff if not for patients. Balconies were preferable for the patients. Finally the architect had to consider the circulation of nurses and staff and the contacts between different departments and between the departments and the outside world. Not until all these considerations had sunk in should he begin to plan his building. Hospital planning was a matter of coöperation and sympathy between all parties, and the more they got together in the earlier stages the greater the chances of getting a hospital that was medically perfect, economical to run, and architecturally satisfying.

Mr. E. ROCK CARLING described a recent visit to a new nurses' home of admirable architectural proportions in which nurses on the top floor could not see out of their windows! No profession suffered more from vexatious amateur interference than the doctor's; he understood therefore that architects might well object to it. Nevertheless many reforms in medicine were due to pressure from outside. The architect's method of remuneration was a grievance in that it did not encourage the architect to minimise the final contract price. New methods involved arduous calculations and much anxiety, and finally left the architect with a smaller fee. The less competent the architect the more the employer had to pay. An attempt to change this old custom would carry most of the architects with it. The building of an entirely new hospital should involve reconsideration of all the customs and work of the institution. One member of the staff should follow the patient from his first appearance to his discharge, and members of the staff must attend every day. The potentialities of the almoner's department must be appreciated, and a really competent almoner put at its head. In such a department business methods and records were found, and it should lie between incoming and outgoing patients. There must be complete circulation of the patient, with minor subcirculations. Apparently undue corridor space was demanded, but was well worth while. No offer by a generous donor should allow any one department to exceed its proper proportions, which should be settled on fundamental principles, for this upset the whole working of the hospital's maintenance. No special department should be provided in a general hospital if there were a neighbouring specialist hospital offering that service. To do effectual work in specialist departments there must be special apparatus which could not be used by other departments; they must be empty part of the time, but power, heat, and light might be cut off from them during the unused periods. Architects, he supposed, looked on medical men as rather like the traditional Irishman who never knew what he wanted and was never happy till he got it, but it was not wholly the fault of the medical man; as soon as he got a plan on to paper his neighbours at once started suggesting alterations.

Dr. RENÉ SAND, technical counsellor of the League of Red Cross Societies, and former president of the International Hospital Association, spoke on

Hospital Administration on the Continent

On the continent, he said, the voluntary hospital was not in the foreground. The matron, when she existed, had not the same authority, and the historical background was different. France and Belgium were typical of countries in which the hospitals belonged mainly to the local public assistance authorities. The result was that on one side the board of hospitals was constantly warned by the municipal authorities that they must economise, while on the other side public opinion cried out for better institutions and equipment. Half-measures were the rule. Some Paris hospitals were at times so crowded that an 18-bed ward housed 30 patients. Hospital technique was hardly recognised as such, and the members of hospital boards were well-meaning citizens who judged things by "horse sense." No general plan had been put into force and there were still many antiquated, dilapidated small institutions. Even in the bigger hospitals few nurses had received a regular training, the science of dietetics was unknown, and accounting was a list of receipts and expenditure. Nevertheless, great improvements had taken place, and hospital technique was forging its way. Italy and Spain were both making great strides with their hospital work.

Germany and the Scandinavian countries represented a second European group in which hospital administration was partly separated from the public authorities. Austria had in 1920 passed a law establishing a hospital plan for the whole country. In Scandinavia the planning, maintenance, and administration of hospitals had for centuries been the function of the State, and the running and equipment was on lines parallel with those in this country. In Turkey the law provided that every province should have its hospital, and a school for the training of Moslem priests had been found to fit admirably the purpose of a child welfare centre. In every direction there was progress and grounds for optimism.

A paper on

Coöperation between Voluntary and Municipal Authorities

was read by Sir GEORGE NEWMAN. He submitted a table showing the actual position of the four classes of hospital—monastic, educational, charitable, and municipal—at the present time, and pointed out that the convenient division into municipal and voluntary institutions was less definite than formerly because voluntary hospitals were more and more engaged in municipal service, while municipal hospitals were adopting voluntary principles. There was no reasonable cause of war between them; there was cause only of marshalling them together in a joint war against disease. The problem was constituted by the fact that the municipal hospitals were maintained on a basis of rates and taxes, and as they expanded there might seem to be less need for the hospital supported by voluntary contributions. Nevertheless, it was far better to combine the two into one coöperative system than to allow the voluntary hospital to disappear. Great as were the services of the voluntary hospital system to the country, it had not met and could not meet the ever-widening and importunate medical needs of the population. The voluntary hospital stood for individual enterprise and self-denial; the municipal hospital for the formulated will of a free people. Clearly, one single health authority must serve the whole hospital needs of its area and the Local Government Act of 1929 sought to ensure coöperation between all the institutions in a district. More had been done by the authorities in support of voluntary hospitals than some people seemed to assume. No less than 300 local education authorities had paid very substantial sums to over 600 voluntary hospitals, for example, and the London County Council paid a yearly grant of some £25,000. Moreover, there had been much interchange of function, yet coöperation could not take place until the voluntary hospitals had established a representative committee prepared to act. This must be done by the hospitals themselves. It was obvious that the greater the goodwill and desire for coöperation the more fruitful would be mutual consultation. Nothing was so conducive to the dissipation of apprehension as a frank discussion of the situation. The survey reports of the medical officers of the Ministry of Health showed that the desire for common-sense coöperation was widespread, but there had been some indication of a fear on the part of voluntary hospitals. As a matter of fact, different authorities could not afford to engage in wasteful competition.

Lord COZENS-HARDY (chairman, Merseyside Hospitals Council) feared that the voluntary hospitals were being slow to realise the immense changes which must follow the Act of 1929. Already the local authorities had the majority of the total number of beds in the country. Nothing effective would be done if coöperation was confined to Section 13. There must be some joint committee, meeting regularly. Suspicion and prejudice were impossible foundations for coöperation, and such a committee might quite unconsciously do great educational work. It would also prevent any political action tending to antagonise the two systems.

Mr. L. G. BROCK (president, Board of Control) gave practical illustrations of coöperation in the field of mental hygiene: out-patient clinics at general hospitals, and the treatment of mental patients by specialists of all branches. Committees had been advised to put physicians and surgeons on the staff of the mental hospital while the psychiatrist was put on the staff of the general hospital.

Dr. FLEMMING said that some people had looked on municipal hospitals as a disease to be avoided and not as what they in fact were—allies in the fight against disease. A volunteer was no good unless he was a member of an organised army. The municipal hospitals were the complement of the voluntary hospitals and not in competition with them. His only fear of the municipal hospital was that the men working it might be overcome by the dead weight of officialism.

Mr. S. HUTTON (Glos.) mentioned certain difficulties of rural areas: poverty, staffing, and communication. He described the methods of coördination already established in his district. He recommended that the chairman of the voluntary hospital should be elected to the local authority. Mr. J. HENDERSON (Sheffield) and Mr. FOUCHARD related the coördinating work in their towns.

Hospitals Conference Banquet

The DUKE OF YORK presided at the banquet held in the Guildhall on June 14th. Replying to the loyal toasts he said that the great voluntary hospital systems of the country represented 1051 hospitals and 83,051 beds, and was a national asset of which everyone was very proud. Year by year, despite anxieties, it was expanding and declaring anew the determination of the people to extend help to the sick and suffering; some 2000 beds were added annually, as well as new appliances and equipment. The way in which the public contributed to the hospitals was wonderful.

His Royal Highness also proposed the toast the Voluntary Hospitals of Great Britain and Ireland, to which Lord STANMORE replied, confessing that even in the blackest financial periods the hospitals found their needs met. It was almost unknown for an institution to close down for lack of funds. The voluntary hospitals possessed the confidence of the people. The system was elastic, and as each new need arose some method of meeting it was found. He was confident that research work flourished more in a voluntary than in a compulsory atmosphere. Major R. JACKSON, also in reply to this toast, spoke in appreciation of the great interest taken in hospitals by members of the Royal Family, and of the valuable work done by officers of the conference.

Lord MACMILLAN proposed the Lord Mayor and Corporation of the City of London, saying that it was the ambition of every cause in the country to have a banquet at Guildhall. The essence of a voluntary movement was that it was independent and retained that sense of freedom and liberty that was our greatest heritage. Often in history the Lord Mayor and citizens of London had turned the scale in favour of liberty. No worthy object ever came to Guildhall and asked for sympathy and support in vain. The Lord Mayor replied, sketching the work of the Port of London sanitary authority in the Thames.

The health of the guests was proposed by Sir HAROLD PINK, who declared that nothing bound nations together better than hospital work; in its pursuit all animosities were forgotten.

Lord HORDER replied, saying that the guests had two common interests: gratitude for the hospitality accorded them and concern for the problems of hospital administration. Many of the guests had worked for years in the service of the voluntary system. The British ideal of the voluntary system was being watched very closely, and some were not too happy about it. The question of coöperation with municipal hospitals was vital and precarious. There seemed to be no sense of permanence in some of the methods of grouping voluntary hospitals. The voluntary system must go on, but it might be modified and adapted to changes in municipal and public life.

THE COMMITTEE AGAINST MALNUTRITION

THE first public meeting of this committee was held on June 13th at 34, Red Lion-square. Sir Gowland Hopkins, P.R.S., was in the chair. The gathering was so large that an overflow meeting had to be arranged, which was addressed in its turn by the speakers.

Sir GOWLAND HOPKINS said that he would have been glad to be present in any capacity, so great was his sympathy with the meeting. The outstanding social duty of the moment was to see that all classes of the people were properly nourished. It was even more important than to see them properly housed. To be poorly housed and well fed was preferable to being poorly fed and well housed. Any sound housing policy must go hand in hand with a sound feeding policy. There was no doubt that an increase in rent, which was often demanded by better housing, meant a decrease in food, and this, in present circumstances, was calamitous. The abundance in the world was common knowledge. Science and enterprise had reproduced the miracle of the loaves and fishes. But they were not being fed to the multitudes. It was important to remember that the multitudes needed fishes as well as loaves. Man could not literally live by bread alone, nor even by bread plus cheap sugar and margarine. Quality was important as well as quantity. The aims of the committee were non-political. They were to give the widest publicity to facts, which could then be used by whoever wished to initiate political demands and campaigns. The necessity for quick action should be kept to the front if the physical descent of the nation was to be arrested.

The inhibitions to proper progress were apathy and disbelief in a few, ignorance in many. A nation which knew that malnutrition existed was a sinful nation.

WOMEN AND CHILDREN

Dr. **Stella Churchill** spoke of malnutrition as it affected women and children. The condition of the pre-school child, she said, was most serious. In any case it was useless to give free education if we did not first give free food. In an examination of pre-school children made at Bermondsey, Dr. Churchill had found that 70 per cent. of babies of one month were over weight, whereas only 30 per cent. of one year were over weight. As soon as they were weaned the children began to deteriorate, and the deterioration continued until they reached school age. Leaving out nursery schools, which at present only touched a minute fraction of the population, there was no State supervision or nourishment for children between the ages of two and five. These children entered school as delicate, "chesty," ricketty subjects, ripe to take all forms of infection. The "chesty" child became later on the tuberculous child, the ricketty girl of five became, through malformation of the pelvis, a factor in maternal mortality. We were sated with sentimental appeals, Dr. Churchill said, to help sick children in hospital. If we fed the children properly, they would never get there. All surgical tuberculosis, for instance, could be prevented by proper feeding. Turning to the women, Dr. Churchill said that the mother of the family was the last to be fed. Women did not die of starvation every day, but they existed in a state of semi-starvation. By the time these women came to labour they were totally unfitted to bear the strain of it. They had difficult confinements, slow recoveries; sometimes they died and left their children worse off than ever. The present was a time of national emergency. We heard much at the moment about the drought, but little about the famine. But it was famine when the allowance for a child was two shillings a week. In some places in the country water was being taken round in carts. Food needed to be taken round in carts. There should be a floating kitchen visiting the people's homes, where they could get a dinner in exchange for a voucher. Lack of money could not be urged against proposals for feeding the people. The Road Fund had better be a food fund and national money put aside for a sinking fund had far better be sunk in the starving stomachs of children.

LEGAL AND ADMINISTRATIVE ASPECTS

Dr. **R. A. Lyster** said that he had been asked to deal with the legal and administrative aspect of the subject. This was important, for it was often possible to start a wave of enthusiasm, which in its turn provoked an official announcement, and the official announcement had power to make the enthusiasm wilt away. For example, the B.B.C. had lately broadcasted talks from the unemployed. These had caused a strong response in the national consciousness. Then came the official utterance, in time-honoured form. It was said that if all the facts were known there would be no tragedy; that there was a statutory obligation upon all local authorities to relieve need where need was proved. It was the truth, but an example of how the truth could be uttered with disastrous effect. For there was no definition of need. The local authorities were the umpires of need and could refuse help or not as they thought fit. Dr. Lyster was a member of a public assistance committee in a reactionary district, which decided not to help anybody who was in receipt of unemployment pay. It was given out that it would be useless for such people to apply. Such conduct was the cause of much starvation. There must be national standards. Otherwise local authorities were free if they wished to disregard their statutory obligations. Taking another example, Dr. Lyster said that about a year ago it was beginning to come home to people that there were millions of their countrymen below the starvation level. All authorities reported an increase in sickness and tuberculosis. The decline in tuberculosis was arrested as it had been during the war. Figures published at this time showed that four shillings and sixpence was the amount allowed by poor-law institutions, who could not be thought to be unreasonably indulgent, and had the advantages of institutional catering, to keep a child in health, while the State allowed two shillings. At this point we read in the report of the Ministry of Health that "there was no available medical evidence of any increase in sickness or mortality owing to depression or unemployment." If this evidence was not available at the Ministry of Health, Dr. Lyster said, the Ministry of Health was the only place where it was not available. The report also pointed out that except in localised areas there had been no increase in physical disability owing to unemployment. In fact, Dr. Lyster said, if we ruled out the bad places, England was doing well. When the Ministry of Health declared that there was not much available evidence it meant that there was not much of this evidence in the reports of medical officers of health for 1932, but the officers were bound by restrictions. Also although the public health service was preventive in aim, it only met the casualties. The Ministry of Health was waiting for the casualties of malnutrition. Again, in the Maternity and Child Welfare Acts of 1918 and 1929, the care of the mother and the young child was given over to the local authority. There was no limit to what might be spent. Yet the local authority commonly neglected this charge. In the same way the power under the Education Act to provide free meals for school-children was neglected. Local authorities entrenched themselves behind the terminology of the Acts, which said "may" instead of "shall."

For £7,500,000 a year half a pint of milk could be given to every elementary school-child in the country daily, but in the present state of legislation, Dr. Lyster said, it was difficult to say what milk was. There was no standard either of cleanliness or of quality. Milk was anything that could be proved to have been squeezed from the udder of a cow. Proof was by the oath of the vendor and his milkman. A county bench of Dr. Lyster's acquaintance had the stainless record of having dismissed every milk prosecution brought before it in twenty years. People were naturally giving up hope. In another famous milk prosecution it had been proved to the satisfaction of the judges that a normal constituent of milk was cow manure.

STANDARDS OF NUTRITION

Prof. **J. B. S. Haldane** said that it was now known what people needed in the way of food. It was no longer a matter of theory. The scientist working on this subject in the laboratory had come to the same conclusion as the worker in other fields. We could lay down a definite standard of nutrition. It used to be thought that as long as a certain number of calories were supplied to the body it did not matter in what form. A fact known now was that proteins had specific dynamic action, that they produced more heat than other foods for the body when it was at rest. It was known that protein was necessary for repair and growth, and was therefore of particular importance to children. It was known that all proteins were not equally good. The right kind of protein cost more than the wrong. The need for the inorganic constituents of food, for lime, phosphorus, and salt was now understood, also the necessity of vitamins. The lack of vitamins did not show for a long time. Teeth, for instance, would be bad in later life owing to lack of vitamins in earlier life. Thirty years ago it was conjectured that "a little of what you fancy does you good." We were now able to give this important statement a more scientific form. When research made a standard possible, then it was time for public action. It was only sixty years since a standard for water had been discovered. Since then cholera and other diseases from bad water had disappeared. We could do the same about food as our ancestors did about water. If our ancestors of the eighteenth century had demanded a pure water-supply from their government they might reasonably have been refused. Neither the knowledge nor the pipes for conveying water were in existence. But now both the food itself and the knowledge about it were in existence. The food-supply, like the water-supply, should be part of the public health service of the country.

Mr. LE GROS CLARK, hon. sec. of the committee, said it owed its foundation to the belief that thousands of people were perturbed about under-nourishment and did not know what individually to do. The committee wished to make practical proposals to these people and to give them information to be used as the basis for logical discussion. With such information they could undermine complacency, which would be left without an argument against proper feeding for all. The committee could elucidate, for instance, the position of local authorities of the type Dr. Lyster described. It could inform its associates, who must be for the most part ignorant on this question, how milk and free dinners were supplied to children in L.C.C. areas. It could give revelations of conditions in various parts of the country. It could give people the stimulus to get to work locally and to start movements locally, out of which a national movement would grow.

An eager discussion followed the set speeches. Dr. ELWIN NASH, having declared his sympathy with the aims of the committee, said that it was impossible to lay down a standard of nourishment. He described his practical researches into the subject of food and his attempts to provide a satisfactory diet on the very smallest amount of money. It was objected that this was an attempt to put up with malnutrition rather than to overcome it. A dietetic experiment made in Scotland was quoted, in which half of a number of children were fed with certain supplementary substances to see if they improved therewith, and half were not. No difference was noted, so that the result was nil, but there was a conclusion—namely, that all the children were too undernourished for the experiment to have any effect. Several teachers spoke of the impossibility of administering education to children who needed food.

CLYDACH WAR MEMORIAL HOSPITAL.—A children's ward of this hospital, with eight beds, nurses' quarters, and the usual appurtenances, which has cost £2000, was opened recently. The Mond Nickel Company and Messrs. John Player and Sons undertook to bear between them such part of the cost as was not covered by subscriptions. The ward is a memorial to the late Mr. John Player, a benefactor, and a tablet to his memory was unveiled by his son, Mr. W. J. P. Player.

MEDICINE AND THE LAW

Problems of Miners' Nystagmus

THE Workmen's Compensation Act was amended in 1931 to remove doubts arising out of litigation about miners' nystagmus. In the House of Lords last week Lord Tomlin said it was a pity that the 1931 amendment had failed to make the position clear. In Bevan *v.* Nixon's Navigation Co. the miner had suffered from nystagmus, an industrial disease which counts as an accident within the course of the man's employment. Unfitted by his disability for his old work at the coal-face, Bevan was able to do light work on the surface at the colliery, but no such work was available. In the circumstances was he still to be deemed suffering from the industrial disease and was he entitled to compensation as for total incapacity? Bevan having lost his case in 1929, the 1931 Act attempted to give a remedy. Thenceforth compensation was to be given to men in his situation if (*a*) they would probably be able, but for the continuing effects of their injury or disability, to obtain work in the same grade in the same class of employment as before the disablement, and if (*b*) their failure to get work was wholly or mainly a consequence of the injury or disability. In French *v.* Archibald Russell Ltd. (the case before the House of Lords last week) the medical referee certified that French was "recovering from an attack of miners' nystagmus, and his condition is such that he is fit for his usual work as a miner." The evidence showed that no colliery in Scotland will employ a workman underground unless he can sign a declaration that he has not previously suffered from miners' nystagmus. Obviously French could not truthfully sign such a declaration; consequently he could never get work below ground in the same grade and in the same class of employment as before the disablement. Was his inability to sign the declaration one of the "continuing effects" of the industrial disease? The Scottish courts held, and the House of Lords has now held also, that the words "continuing effects" must relate to the physical state of the workman and not to any artificial conditions imposed by the employers. Thus the workman loses his appeal and Parliament will probably be asked to try once more to clarify the law.

Two Disablements from One Disease

Another nystagmus case occupied the Court of Appeal last week on a different point. In Timmins *v.* Brodsworth Main Colliery the miner was certified in April, 1928, to be suffering from miners' nystagmus. No date was given for the disablement caused by the industrial disease, and therefore (under Section 43 (2) of the Act) the date of the certificate was reckoned as the date of disablement. Timmins, the miner in question, was paid 30*s.* a week for compensation at the full rate till September, 1929, when he went back to try his old work again. He worked till January, 1930, when his eyes gave him trouble and he had to stop. From this point he was once more paid compensation at full rates until the following October when light work was found for him on the surface till January, 1932. Afterwards he resumed his old work underground for most of 1932, but eventually he had to stop owing to a septic throat and eye trouble, and on Jan. 7th, 1933, he was certified for the second time to be suffering from miners' nystagmus. In this second certificate the date of disablement was again left blank, so that again the date of disablement was the date of the certificate.

Timmins was now paid compensation at the rate of 24*s.* 7*d.*, based on the reduced wages he had been receiving up to the date of the second certificate. He reasonably contended that his second disablement was a recrudescence of the same industrial disease as had caused his first disablement; he therefore claimed to go back to compensation at the original rate of 30*s.* The county court judge agreed with him, finding as a fact that there had been no complete recovery from the original disease. But the Court of Appeal has overruled the county court and has decided in favour of the employers. The Master of the Rolls says that, when Timmins went back to his old work, it was an overt act, indicating that the effects of the first disablement (or "accident") had passed away. By leaving blank the date of the second disablement the certifying surgeon had unequivocally declared that date to be the date of the certificate. The county court judge had no evidence on which to ignore the definite date assigned to the second disablement, and the workman was not at liberty to choose which of the two certificates might best suit his claim. Lord Justice Romer concurred with the view of the Master of the Rolls but, as the workman secured a minority opinion in his favour from Lord Justice Slesser, the case will doubtless be taken to the House of Lords.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY

ANNUAL MEETING

THE annual meeting of this society was held on Wednesday, May 30th, at Victory House, Leicester-square, when the President, Sir John Rose Bradford, moved the adoption of the report and statement of accounts for the past year, drawing attention to the position and work of the Society. He was able to record a notable increase of activity during the year both in the number of applications for advice and in the number of cases that required serious consideration, and he added that many settlements had been arrived at which, as shown by letters afterwards received, had proved satisfactory to the members. While, however, he said the membership of the Society had increased, he felt obliged to point out that many doctors, perhaps one-third of the men on the Register, were not members of any defence society, a position which he held to be no exaggeration when it is described as appalling, considering the multifarious risks to which the doctors are exposed in the course of practice. He referred to the death of Sir George Makins, a very old member of the Society who had acted as vice-president and who, though taking little part in the routine business, had shown himself greatly interested in their activities. Sir John closed with an eloquent testimony to the officers of the Society, and the motion that the annual report and statement of accounts and balance sheet should be adopted was carried unanimously.

The meeting proceeded to the election of officers. Sir John Rose Bradford was re-elected president and re-election was also extended to the vice-presidents to which body Sir William Hale-White and Sir Cuthbert Wallace were added. Dr. C. O. Hawthorne endorsed Sir John Rose Bradford's words as to the risks run by practitioners who belong to no defence society and said that the British Medical Association took every opportunity of urging upon the younger members of the profession to become members of one of the defence societies, but, he added, the annual report before the meeting had led him to conclude that it is no less important that members of the profession of riper years should maintain their association with one of these bodies; these might also, through their influence, bring their colleagues into the fold.

Dr. R. L. Guthrie, who was unanimously re-elected treasurer, made a brief statement as to the situation of the finance of the Society for 1933, describing the balance sheet and accounts as disclosing a satisfactory position. The assets had increased by over £5000, and there had been an appreciation of nearly £10,000 in the value of the investments, but he warned the audience that the present position of gilt-edged securities was not permanent, and that some of the appreciation would disappear. The facts that the legal expenses for the year were down, and that the liabilities for costs and damages were lower by nearly £3000 were mentioned, but Dr. Guthrie believed that the circumstances of 1933 were exceptional, while expenditure in the current year might be larger on account of certain outstanding cases.

Dr. C. M. Fegen was re-elected as secretary, a resolution to that effect being carried with applause, as his complete familiarity with the onerous and responsible duties was well known to the meeting. A cordial vote of thanks to Messrs. Le Brasseur and Oakley, solicitors to the Society, elicited the information that during 1933 the firm had dealt with about 650 questions and cases.

At the close of the meeting at the instance of Prof. Mary Lucas Keene appreciation of the work of the president, Sir John Rose Bradford, was warmly expressed.

IRELAND

(FROM OUR OWN CORRESPONDENT)

FINANCIAL POSITION OF THE IRISH HOSPITALS

THE Hospitals Commission, which was appointed last September by the Minister for Local Government and Public Health to advise him on the distribution of the funds accruing from the hospitals sweepstakes, has presented a preliminary report dealing with the financial position of the hospitals participating in these sweepstakes. The report points out the difficulties arising from the absence of a uniform system of accounting in the different hospitals. The Commission, therefore, prepared a system and requested the hospitals to adopt it, fixing the end of their financial year at Dec. 31st of each year. The hospitals willingly accepted the scheme, and thus for the first time in the history of the Irish hospitals it has been possible to make a review of hospital finance. The report states that 35 hospitals show for the year 1933 deficits amounting to £65,000; 15 hospitals show a surplus. The amount invested by the voluntary hospitals out of sweepstake funds is £1,451,000. The total deficits, if income from the funds so invested had not been available, would have amounted to £105,000. The sum required to meet the net deficits, if capitalised at 3½ per cent., would be £1,800,000. The Commission noted, comparing the years 1929 and 1933, the only years for which figures are available, that there has been an increase in the number of free patients of from 10 per cent. to 50 per cent. If this were an indication that a larger number of patients unable to pay for treatment were now receiving free treatment, it would be a high tribute to the usefulness of the sweepstakes. The Commission do not draw this conclusion, but point out that many of the hospitals complain of an increasing difficulty in receiving payment from patients who are in a position to pay, since the public appear to believe that the sweepstake fund has now reached a figure whereby all may be treated free. "Until such a time," the report goes on, "as hospitals have developed a system whereby patients in a position to pay can be identified without difficulty, a continuance of the present heavy deficits on maintenance, if not an actual increase, may be anticipated." Such a system is at present being devised, but considerable time must elapse before its application will be feasible. The Commission have observed also that since the advent of the sweepstakes there has been a notable decrease in voluntary subscriptions, a factor which also tends to increase the working deficits. Taking a representative group of seven hospitals there was, from 1929 to 1933, a drop of 67 per cent. in voluntary subscriptions.

Passing from the working requirements of the existing hospitals, the Commission consider their plans for development in the future. The claims of the hospitals for increased accommodation amount to close on 3000 beds. If these claims were met, and assuming that half the beds were self-supporting, a modest estimate of the additional deficit would be £150,000 a year, or, at 3½ per cent., a capital sum of over £4,000,000. The capital cost of providing, equipping, and furnishing the additional bed accommodation claimed is estimated to be approximately £7,000,000. From a consideration of the expected income from sweepstakes and the other calls on such funds, the Commission estimate that it will take approximately seven years before the financial position of the voluntary hospitals as reconstructed, enlarged, and equipped in accordance with the claims submitted, will be secure. It may be that the claims are in some degree excessive; the Commission emphasise the necessity for moving slowly where expenditure of large sums is proposed, except in cases where rebuilding, extensions, or alterations on a large scale present "in addition to their urgency, such an improved hospital service that the risk is well worth the taking." In conclusion, the Commission state their desire to establish a hospital system of which the country can be proud and their appreciation of the coöperation shown by all those concerned in hospital management. The report, brief and general as it is, shows a sound grip of the financial situation and embodies a great mass of work and serious thought.

PARIS

(FROM OUR OWN CORRESPONDENT)

THE ACRODYNIA OF YESTERDAY AND TO-DAY

In a recent communication to the French Academy of Medicine, Dr. M. Péhu[1] of Lyons drew attention to the curious vagaries of a disease which a century ago swept down on Paris with fulminating violence and which lasted only for two or three years. It seems to have died out, completely escaping notice for some fourscore years, and then to crop up again as an endemic but comparatively rare disease, with certain salient features profoundly modified, and yet retaining so many of its original characteristics that there can be little doubt as to its identity in the two periods. When acrodynia overtook the Parisians about 1827, its ravages were such that some 40,000 cases were recorded during a brief interval. Chomel described it with more truth than accuracy as a "maladie actuellement régnante à Paris." The term "chiropodalgie" was more informative, but it was discarded in 1930, when Chomel returned to the charge with the more appropriate title of acrodynia which has survived. According to the records of 1830, the disease gave rise to disturbances of the cutaneous, nervous, digestive, and respiratory systems, with involvement of the sweat glands. Symmetrical redness of the hands and feet ceased suddenly at the ankles and wrists. Brown, and even sometimes black, discoloration developed, desquamation was frequent, and the attacks of pain were refractory even to large doses of opium. Children were much less liable to the disease than adults and the aged, and the mortality was far from negligible. The disease disappeared as mysteriously as it came, and nothing was heard of it again till 1903, when a Dr. Selter, of Solingen in the Ruhr, published a very detailed report of a case. In 1916 the Australian, Swift, rediscovered the disease, and Weston in 1920 restored its old and proper title to it. During the past 30 years it has cropped up only now and then and has shown a predilection for childhood, notably from 1½ to 5 years. But slightly contagious, the disease runs a slow course of several months and usually ends in recovery. Relapses are exceptional. It is, indeed, a remarkable fact that, with so many different manifestations, cutaneous, circulatory, nervous, and nutritional, the disease should clear up ultimately without leaving any permanent ill-effects. This problem of a disease which undergoes profound changes in the course of a century is of exceptional biological and epidemiological interest.

TYPHOID FEVER IN PARIS IN 1933

The behaviour of typhoid fever in Paris last year was both instructive and puzzling. Quite recently great improvements have been effected in the Paris water-supply by chlorination and expert interference with the hitherto deplorably common and fortuitous liaison between drinking and other water. Considered as a water-borne disease, typhoid should, therefore, have shown a definite decline last year. So it did, but only up to a certain point. In 1931 1324 cases were notified, and in 1932 1251. From the first of January, 1933, to November of the same year, only 473 cases were notified, and it looked as if this year was going to set a record. But it was badly spoilt when an epidemic broke out in November and claimed still more victims in December, with the result that 922 cases had to be recorded for the whole year. This outbreak coincided with exceptionally cold weather—a factor of considerable importance in a town like Paris in many of whose cellars water may be tapped from two sources—drinking water, and washing water straight from the Seine. This water is the cheaper of the two, at any rate at the moment, and when pipes are frozen or burst, the claims of false economy are re-enforced by dire necessity. The authorities are now trying to eliminate the temptation which this double water-supply offers. Though polluted water was probably responsible for much of the typhoid, no very convincing correlation could be established between the distribution of the cases and the various water-supplies of the areas in which typhoid was most rife. Nor could any foodstuffs or carriers be singled out for special blame. So typhoid remains still, to a large extent, an unsolved problem with us.

UNDULANT FEVER IN LORRAINE

Thanks to the investigations of Prof. Jacques Parisot of Nancy, assisted by Dr. Robert-Lévy, the ravages of undulant fever in Lorraine have been brought to light, and measures have been taken to limit its further spread among human beings and cattle. A little more than three years ago the disease was non-existent, or at any rate unknown in this area, and in 1929 only two cases came to light. This figure rose to 20 in 1931, to 31 in 1932, and to 43 in 1933. All these 96 cases have been confirmed by bacteriological examinations. It is, of course, not clear how many other cases have escaped detection; the approximate ratio of slight and abortive to clinically well-defined cases is as yet unknown. Among the 96 cases were three deaths. Encouraging results have already followed the chlorination of the water-supply in certain districts, and it is on these lines that the authorities hope to combat successfully not only undulant fever but also typhoid fever and other water-borne diseases in this area.

---

EVACUATION OF THE WOUNDED BY AEROPLANE IN MAROCCO

An account given in *la Presse Médicale* for May 9th of the campaign in Marocco in 1933, Dr. R. Charlet draws a vivid picture of first aid by the air, contrasting it with the older method of terrestrial transport, with its inevitable delays and sufferings. It would seem that the new arm has replaced the old one to such an extent that, during these operations, the air ambulance service found almost as much employment as the motor ambulances. Smoothly as the former worked, reforms were found necessary in two directions. The ambulance aeroplanes were fitted with one type of stretcher, the motor ambulances with others. This meant the painful shifting of patients from one stretcher to another. The other important lesson was that a rough country demands a type of aeroplane capable of negotiating the most primitive landing grounds.

SPECIALIST OR GENERAL PRACTITIONER?

We used here as elsewhere to be either specialists or general practitioners. Now many of us are specialists with general practice as a distracting avocation. Or we are general practitioners whose interest in, and almost profound knowledge of, certain subjects render us specialists *de facto* if not *de jure*. But how is the money value of the services we render (*a*) as general practitioners, and (*b*) as specialists to be assessed? When there is no third party, and we have none but the patient to consider, it is comparatively easy to treat him with discriminating benevolence. When the State becomes a third party to the transaction, as in the case of the insured and pensioners, war or otherwise, elastic compromise must yield to rigid rulings. They have been applied not long ago to the by no means rare case of the general practitioner with an X ray outfit. As a general practitioner he may find the opinion of a radiologist desirable in a given case. Accordingly, the radiologist examines and reports. Dr. Jekyll needs information, and Mr. Hyde supplies it. There is nothing sinister about this dual personality, but it has been found to cost the State too much. The State now honours the bills of only those radiologists whose patients have been referred to them by another doctor. It is laid down that one must be either a specialist or a general practitioner; it is not possible, under the conditions described, to be a facultative specialist or an optional general practitioner.

PAYMENT FOR BLOOD TRANSFUSION

As from April 1st, 1934, blood donors in military hospitals in France are to be paid according to a certain scale, 50 francs being the price of the first 150 c.cm., and 50 francs for every supplementary 100 c.cm. These charges are doubled when the donor has been artificially prepared for an immuno-transfusion.

PUBLIC HEALTH

SWIMMING BATHS AND HEALTH

The healthy urge to bathe in the fresh air received little official encouragement until recent times. Well into this century those who wished to swim at any other time than the summer holiday, and who lived far from natural ponds or rivers, were obliged to indulge their craving in small rectangular pools surrounded by a narrow gangway giving access to a row of small clammy cells. The dust or mud deposit on the gangways from the bathers' shoes was for the most part carried into the bath on their feet after undressing. The water was changed perhaps two or three times a week—on days well known to the more experienced bathers. Fresh air and direct sunshine were excluded by a skylight, and by the time the bath came to be emptied the water was of a grey colour and so opaque that bathers could drown, and not infrequently did, without being noticed.

All this is changed. Swimming has become a popular pastime, and every up-to-date municipality provides open-air baths where persons of both sexes can swim, bathe, and bask in the air and sunshine. The extensive use of swimming baths has led to a much better lay-out, and continuous purification of the water is fast replacing intermittent emptying; in fact many baths are so large that the time needed for emptying would put them out of use for an inconveniently long period, and the cost of repeatedly heating such a volume of water would be prohibitive. The assembly of large numbers of bodies in a limited mass of water which is not renewed, but only made up to constant volume, and in which they may spend hours at a time and take active exercise, may lead people to ask their doctors whether they or their children should go to public swimming baths, and the answer needs some consideration.

Every bather, however clean his habits, brings into the bath not only the dirt from his shoes, but dried sweat, grease, bacteria, probably moulds, and miscellaneous dirt accumulated on his skin. After a day at school or at work this accumulation may be considerable, especially if his opportunities of washing and bathing are small. The individual contribution to the bath water may seem insignificant, but if every bather enters the water without preliminary ablution it will soon become obviously dirty as well as bacterially contaminated. Infection of the mucous membranes and of the middle ear have frequently been associated with bathing, and in any case few people would care to bathe in dirty water if they were offered clean. It is therefore desirable that bathers should not reach the undressing rooms by walking along the edge of the bath, and that they should have some means of cleansing the skin, and especially the feet, before entering the water. This can be done by making them pass on their way to the bath under a shower of sterilising water and through a trough filled with similar water. As some do not like cold showers, it may be advisable to have this water warmed. The best way of cleansing the feet is by means of a spray which impinges on a raised platform on which the foot can be placed; this is likely to clean the spaces between the toes which are specially subject to cracks and sores. All this applies to relatively clean people. Others should have further opportunities of cleansing or be sent away.

Having regard to the effect of cold water on urinary excretion it is desirable that urinals should be situated on the way to the bath, and that children should be required to use them before going into the water.

A bath may be used by none but the cleanest bathers and yet the originally clean water will become contaminated with both dirt and bacteria. Only in those rare cases where water is derived direct from springs, like the hot baths at Bath and Matlock, is it practicable to let water run to waste through the bath. Some means of continually purifying the water is needed. This is achieved by pumping water from the deep end of the bath, coagulating the suspended impurities to form a thin turbid emulsion, filtration through sand, and final sterilisation of the now clear and relatively organic matter-free water. Alum or its equivalent followed by lime is commonly used as coagulant. Sterilisation may be brought about in a variety of ways; the most usual is chlorination, but ozone, catadyn silver, and ultra-violet radiation are all effective if properly used. The process of continual purification if successful will give water which is bright and attractive. As the bottom of the bath is always visible the responsible attendant will be able to see anyone who is in difficulties under water, while such things as cigarette or chocolate cartons and used costumes are less likely to be thrown into water in which they can be seen. The platform surrounding the bath should slope away from the water, and a channel a little above the water level serves both as handrail and spittoon.

Doctors who are consulted by their patients about swimming baths should certainly advise them to avoid public baths not fitted with filtration and sterilisation plants.

Treatment of Bath Water

Small baths can be kept in tolerable condition by simple chlorination, either with chloride of lime or more conveniently with a solution of sodium hypochlorite such as Chloros, if care is taken to add so much as will maintain a suitable excess of free chlorine. One ounce per 6000 gallons is equal to one part per million, and this amount of chlorine is contained in three ounces of good bleaching powder or ten fluid ounces of chloros. To a bath full of clean water rather less than one part per million of free chlorine should be added, care being taken to distribute evenly, and the free chlorine content should be kept up by additions to 0·2–0·5 part per million. This requires daily tests of the water with ortho-tolidene, comparison being made with coloured solutions representing the permissible limits. If the upper limit is not exceeded the water is unlikely to irritate the eyes, and if the lower limit is not reached sterilisation is likely to be unsatisfactory.

FILTRATION

The water will not remain clear for prolonged periods and must be changed before it becomes so turbid that the bottom of the bath at the deepest part is invisible. The use of ammonium salts will help matters, but larger doses of chlorine must then be used and control becomes difficult. Without filtration chlorination is but a makeshift, at best only securing sterility of the water and effecting some economy in its use. The only satisfactory treatment is filtration after coagulation, followed by sterilisation of the clear water, already freed of grosser impurities. This preliminary clarification enables a choice of sterilising agents to be made, and their amount to be cut down to a minimum. The bath is worked as a circulating system and, once filled, very little make-up water is needed to replace losses by evaporation, splash, or overflow at scum channel.

Although some of the impurities introduced into bath water during use can be removed by simple filtration—some indeed, e.g., dead leaves, bathing costumes, by mere straining through a coarse-meshed grid—it is in every way better to introduce into the strained water as it is pumped from the bath a small predetermined dose of a soluble aluminium salt (alum or "alumino-ferric"), followed, if necessary, by sufficient of an alkaline solution (soda ash is the most convenient) to make the liquid alkaline as tested with phenolphthalein. The precipitated aluminium hydroxide will separate with it, either mechanically or by coagulation of colloids, the fine matters in suspension which cause turbidity, as well as those in quasi-solution, in a state removable by filtration through sand. The clear water which passes from the filter contains only matters in solution and bacteria, which have not been removed by the previous processes. Whatever sterilising agent is now used will not be spent in effecting changes on any other impurities than micro-organisms.

STERILISATION

The most common sterilising agent is chlorine, which is best used as gas from steel cylinders. Several firms make plant for coagulation, filtration, and chlorination which is practically fool-proof and requires little attention. If for any reason the handling of a gas cylinder is undesirable the hypochlorite solutions already mentioned can be used; an electrolytic cell is obtainable, specially suitable for small baths. As chlorine is an irritant both to the eyes and nasal passages the amount must be regulated. A simple colour test, with standard limiting tints representing the minimum useful content of free chlorine and the maximum proportion which most persons can tolerate with comfort, is usually supplied with the plant for treatment. The water leaving the bath should contain the minimum and that entering approximately the maximum.

Where an electric supply is available the use of ozone or of ultra-violet rays is worthy of consideration. Ozone has been used largely on the continent for sterilising drinking water, and a plant erected at Barn Elms by the Metropolitan Water Board not only sterilised the water but greatly improved its colour. The residual dose can easily be adjusted so that there is only the merest smell of the gas, which is not unpleasant. Ultra-violet light can be used successfully to sterilise clear well-filtered water and is effective when none of the water flowing past the lamp is more than 12 inches from it and the exposure lasts at least 4 seconds. It should be easy to use a much smaller working distance than this. Advantage may well be taken of the formation of ozone in the region of the lamp, by letting the ozonised air flow through the water, thus giving it some residual sterilising power in its passage through the bath. The shorter waves appear to be the most effective.

A method of sterilisation unlike all the others is the Catadyn process in which the filtered water on its passage back to the bath either flows over sand coated with silver, or a portion of this returning water flows past two silver electrodes between which a small current passes. An extremely small amount of silver ions goes into the water from the anode. The silver introduced in this way or from sand possesses remarkably high sterilising power, provided the water is relatively free from organic matter other than bacteria. No smell is imparted to the water, which retains a sterilising power for some time, exerting an inhibitive effect on green growths. This oligodynamic action of silver and other relatively noble metals, although not well understood, is simple to apply and merits further study.

The economic use of filtration and sterilisation is now made easy by the many makes of plant for this purpose.

A Hop-picking Dispute Settled

As our readers will recall, difficulties have arisen for some years past about the responsibility for the treatment of infectious disease occurring among Londoners who had gone to pick hops during the season in Kent. Last year the London County Council were unwilling parties to the transference of two cases of diphtheria from Kent to their homes in St. Marylebone, and the L.C.C. asked the Minister if it would not be possible to make it obligatory on a local authority to treat persons suffering from infectious disease temporarily resident within its district. As a result of this request the following new regulation is to come into force on July 1st next:

> The London County Council, the council of every borough or urban or rural district and every joint hospital board constituted under the Public Health Act, 1875, and having the powers of Section 131 of that Act, shall have the same powers and duties in relation to the provision of hospitals or temporary places for the use of persons who are for the time being within their county, borough or district, as the case may be, and are suffering from infectious disease, as they have for the use of the inhabitants of that county, borough or district.

The L.C.C. has informed the Minister of its willingness to enforce a regulation of this kind.

At its meeting on Tuesday the London County Council agreed to the proposal of its hospitals and medical services committee to remove to St. James' Hospital the plastic surgery unit at present at Hammersmith Hospital. The transfer will take effect on August 1st next. The arrangement includes the provision of one position of plastic surgeon and one of assistant plastic surgeon for one session a week each at a salary of £125 a year.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 9TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 2 (last week 2); scarlet fever, 2368; diphtheria, 1101; enteric fever, 16; acute pneumonia (primary or influenzal), 939; puerperal fever, 60; puerperal pyrexia, 110; cerebro-spinal fever, 24; acute poliomyelitis, 3; acute polio-encephalitis, 2; encephalitis lethargica, 5; dysentery, 7; ophthalmia neonatorum, 89. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 18th–19th was as follows: Small-pox, 3 under treatment, 0 under observation (last week 3 and 0 respectively); scarlet fever, 1624; diphtheria, 1686; measles, 1750 (last week 1890); whooping-cough, 281; puerperal fever, 22 mothers (plus 6 babies);
269; poliomyelitis, 2; "other disease
Hospital there were 20 babies (plus 7
neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 60 (22) from measles, 5 (2) from scarlet fever, 27 (6) from whooping-cough, 30 (4) from diphtheria, 45 (21) from diarrhœa and enteritis under two years, and 36 (6) from influenza. The figures in parentheses are those for London itself.

Brentford and Chiswick, Southampton, and Worcester each reported a death from enteric fever. Stoke-on-Trent reported 5 fatal cases of measles. Salford 4, Newcastle-on-Tyne 3, no other great town more than 2. Liverpool reported 5 deaths from whooping-cough, Birmingham 3.

The number of stillbirths notified during the week was 271 (corresponding to a rate of 39 per 1000 total births), including 52 in London.

PANEL AND CONTRACT PRACTICE

An Election without Enthusiasm

THE Ministry of Health has decided to keep the present personnel of insurance committees in office for another three years and the Insurance Acts Committee has, with a show of reluctance, agreed to this course. On the other hand the panel committee for the County of London goes out of office at the end of this month and a new committee is now in the course of election. The machinery for this is elaborate. Every practitioner on the medical list is furnished with a list of names and addresses of those eligible for election, who include any doctor in practice on his own account or in partnership. Assistants are not eligible. Each borough has so many seats on the committee according to the number of insurance practitioners in its area. A returning officer is appointed and approved by the Minister; nomination forms are sent out and signed by the candidate as willing to serve after being proposed and seconded by two members of the profession in that area. The date of election is then fixed and a voting paper sent to every insurance practitioner, giving the names of candidates nominated in his borough. The completed voting paper may be posted to the returning officer to reach him not later than the morning of the appointed date or it may be handed to the returning officer at the agreed meeting place; but it may not be sent by proxy to the meeting. After the election it is usual for an address to be given by someone conversant with the past work of the committee. A speaker is selected who does his best to reply to any questions raised of difficulty under the Act.

How well these elections are conducted, what ample precautions are taken to ensure a proper election—may be the thought in the mind of the uninitiated. The facts are different. In London insurance practitioners do not take the slightest interest in these expensive and elaborate proceedings. A recent meeting held in the Battersea Town Hall for the adjacent boroughs of Battersea and Wandsworth was attended by exactly four doctors. Three of these were old members of the panel committee up for re-election and one was a new candidate to be elected. There were five candidates for eight seats for the borough of Wandsworth; three of those seats remain to be filled. Such elections scarcely justify so expensive a procedure. But it may be time for insurance practitioners generally to be roused from the lethargy in which they appear to be living. Medical men who serve on the London panel committee give their services gratuitously; many of them devote hours each week to the work of committees and subcommittee meetings besides representing the panel on insurance committee, medical service subcommittee or after-care committee, let alone accompanying the regional medical officer when making inquiry about excessive prescribing or improper certification. The apathy is found to disappear when a question of finance arises; practitioners are sure to attend a meeting to protest against a reduction of the capitation fee, or to blame the panel committee for allowing such reduction to take place. But they are unwilling to enter attendances and visits on record cards to enable officials to get a proper measure of the total work done—and thereby definitely hinder negotiations on fees. Practitioners might take more interest in the committee's work if they were to pay their representatives; an alternative would be to make service on the panel committee for a certain period obligatory on all insurance practitioners, a procedure which would meet with certain resistance.

The Record of the London Panel Committee

A brief résumé may now be appropriate of the work of the London panel committee, which represents nearly 2200 practitioners, during the last three years. One subcommittee prepared a long and exhaustive argument against the conclusion set forth by the Government in Memo. 329 in which the medical profession was charged with inefficient certification as a cause of increased sickness claims. This took several meetings each of some hours' duration. The panel committee itself circulated prescribing statistics to insurance practitioners pointing out where they exceed the areal average. Certain members of the committee have given lectures gratuitously on health insurance regulations to senior students of various London medical schools. They arranged a conference between themselves and representatives of approved societies for the discussion of vexed questions such as certification in pregnancy, simplification of rules, and the status of sick visitors.

This conference was held in a friendly atmosphere and was perhaps the best piece of work ever done by the panel committee. A deputation from the committee interviewed the out-patient committee of King Edward VII. Hospital fund upon the general question of out-patient attendance. A memorandum upon the adequacy of the capitation fee was sent to the Insurance Acts Committee—another long and arduous piece of work. The payment for temporary resident treatment in convalescent homes has largely been reduced by its efforts. The panel committee is still trying to obtain a better service of medicine to insured persons after closing of chemists' shops. There are many other actions and decisions in which the committee has taken part in addition to its normal routine work, and of these our columns have perhaps given evidence enough. Perhaps the apathy of the election is really a compliment to those who do the work; it is being done so satisfactorily that there is nothing to complain about.

CORRESPONDENCE

"NEW METHOD OF LOCAL ANÆSTHESIA FOR ABDOMINAL OPERATIONS"

To the Editor of THE LANCET

SIR,—The new method of local anæsthesia for abdominal operations used so successfully by Dr. George Bankoff in over 500 cases and described by him in your issue of Feb. 10th (p. 287) was devised by me 13 years ago (Zentralbl. f. Chir., 1921, No. 23). A survey of the literature on this new method which I named "local anesthesia by intra-abdominal clysis" was published by me ten years later (Ibid., 1931, No. 19). This paper covered investigations of ten authors on the subject. No modification of my original method has been developed as far as I know. Up to 1929 novocain was the anæsthetic of choice. I recommended 0·5 g. of the drug in ¼ to ½ per cent. solution together with adrenaline. The results obtained were quite striking from the beginning. There was no doubt that this method was a simple way towards a complete regional anæsthesia of the abdominal cavity. However, the anæsthesia was not perfect with novocain, as novocain is rather a poor surface anæsthetic. The excellent results reported by Dr. Bankoff on over 500 laparotomies, in spite of the use of novocain, are in my opinion the best compliment for the method itself.

In 1929 a decided step forward is to be recorded with the introduction of Nupercaine (also known as Percaine). This drug proved to be far superior to novocain in its action on surfaces and in its penetrability. No wonder that the very first publication on nupercaine pointed explicitly to the "excellent" results obtained in regional abdominal anæsthesia. The author of this paper, Prof. C. Henschen, of Basle, Switzerland, determined the dosage of nupercaine for intra-abdominal clysis as 80 to 150 c.cm. of the 0·05 per cent. solution, a strength generally adopted by later investigators. Among these were: F. Mandle, Clinic Hochenegg, Vienna; M. Richard, University Clinic, Basle; Prof. A. Eiselsberg, Vienna; Abel, Berlin; G. Neumann, Muerzzuschlag; H. Gangle, Berlin; Prof. E. Payr, Leipzig.

Great care should be taken not to use excessive doses of nupercaine as it is almost as toxic as cocaine. For this reason, nupercaine in its present method of use is as yet not ideal for our special purpose of intra-abdominal anæsthesia. Further research is being carried on, in the hope of developing a less toxic solution by altering the vehicle. There is also a new local anæsthetic, Metycaine, under my investigation that seems to be very active by topical application to surfaces and has a toxicity comparable to that of novocain. Reports published on this anæsthesia corroborate unanimously my favourable results. A number of enthusiastic surgeons proclaimed it the future standard anæsthetic of the abdomen. The veterinary surgeons, Prof. W. Lindner and W. Hinze, University of Berlin, consider the method revolutionary in their special field. Certain advantages of the method are indeed quite superior to other methods of regional abdominal anæsthesia. The administration is very simple. The duration is prolonged—at least twice that of spinal anæsthesia. The intestinal peristalsis is not interfered with, &c.

More details may be found in my above-mentioned survey of the topic. This communication is not so much intent upon establishing priority of the method as against Dr. Bankoff's. It means to encourage other surgeons to give it a fair trial.

I am, Sir, yours faithfully,

MAX BARUCH,

Director, Surgical Department, Central Neurological Hospital, New York City.

June 3rd.

HISTAMINE IN RHEUMATISM

To the Editor of THE LANCET

SIR,—The article by Dr. B. Shanson and Mr. C. G. Eastwood in your last issue (p. 1226) is of interest [illegible] confirming work already published on the and in this country on the effects of histamine in rheumatic conditions, but a more detailed account of the clinical results in the various types of cases treated would have been of value. Only one type of case seems to have shown marked improvement when treated by the hypodermic method—viz., peri-articular arthritis in the hand with circulatory disturbance. They were unable to obtain any clinical evidence of the characteristic histamine effect by ionisation methods and attribute the results to local galvanism, heat, and counter irritation only. They are alone in this finding however, as other observers appear to obtain readily the complete gamut of physiological effects by this method, as by the use of histamine hypodermically.

That the response to histamine varies from patient to patient and at different times in the same patient is surely an argument against injection, as ionisation can be so regulated that no untoward systemic symptoms need ever arise. Having prescribed over 3000 histamine treatments at the Royal Baths, Harrogate, during the last three seasons, my findings are that good results may be definitely obtained in many types of rheumatism. Identical results are reported by Dr. McKenna and various continental writers. I am, Sir, yours faithfully,

Harrogate, June 12th. A. A. BISSET.

THIOL-HISTAMINE

To the Editor of THE LANCET

SIR,—My attention has been drawn to certain articles you have published recently upon preparations of histamine for rheumatism, wherein whatever credit is due for their discovery has been given to German workers. I introduced thiol-histamine in 1917, since when I have used it on a large scale. Frequent references have been made to the preparation in my works on the Nature of Disease, and you were kind enough to publish a letter for me on May 6th, 1933. May I ask you to be so kind as to correct the omission to which I am referring.

I am, Sir, yours faithfully,

J. E. R. MCDONAGH.

Wimpole-street, W., June 16th.

DISTRICT ALMONERS

To the Editor of THE LANCET

SIR,—It is now generally recognised that almoners are indispensable in all our hospitals; and suggestions are being made that there should be district almoners, whose services would be available to all.

It is unnecessary to tell those who have worked on the visiting or resident staff of a hospital in recent years what an almoner can do, but there must be many in practice who have never been able to write upon a hospital patient's card "Will the Lady Almoner please do this or that," and consequently many who do not realise how much an almoner can do to help to get the best results out of treatment. It will interest these to know that the almoner can usually procure all those things for a patient that doctor or nurse cannot procure: abdominal belts, and all other types of surgical appliances, extra nourishment or particular articles of diet, dressings, and special care of any sort for those otherwise unable to obtain them.

Patients with advanced cancer; those with Graves's disease whose home conditions are unsuitable; children who have come from a distance for the specialist's opinion are recommended treatment with rest in bed and may not even have a bed to themselves; all these and many other similar cases can be dealt with by an almoner.

Convalescence can be arranged, and although the patient at first mention of this may fear the loss of his job by so long an absence, yet it is usual to find that an almoner can approach his firm and get over this difficulty, often obtaining a grant partially to cover the cost.

Naturally the services of an almoner are not for the well-to-do, but with the assistance of a district almoner practitioners could give better service to their patients, such a large proportion of whom are in varying degrees of domestic or financial difficulties.

It would be interesting to hear the views of other practitioners on this subject as it is felt that before further steps can be taken it is necessary to have an idea of the support that can be obtained.

I am, Sir, yours faithfully,

GEOFFREY HALE.

Eccleston-square, S.W., June 16th.

CONTINENTAL ANGLO-AMERICAN MEDICAL SOCIETY

To the Editor of THE LANCET

SIR,—On July 27th at 12.30 P.M. this society will meet for luncheon at the Bournemouth Pavilion on the occasion of the B.M.A. annual meeting. It is hoped that all former members now resident in Great Britain will endeavour to attend on the first such occasion since the war. Any doctors attending the meeting who have patients wintering on the continent will be welcomed at the luncheon. Those who wish to be present should communicate with Dr. E. L. Gros (President) 23 Ave. Maréchal-Foch, Paris, Dr. R. Pryce-Mitchell, Villa Henri, Monte-Carlo, or with the undersigned.

I am, Sir, yours faithfully,

TOM A. WILLIAMS.

Royal Societies Club, 63, St. James's-street, S.W.1,
June 19th.

BIRMINGHAM HOSPITALS CENTRE.—The Prince of Wales will lay the foundation-stone of the *Birmingham* Hospitals Centre at Edgbaston on Oct. 23rd. On the same day he will cut the first sod on the site of the Birmingham University Medical School, which is an integral part of the hospitals centre project. It is expected that the first portion of the new hospital will be ready for opening in October, 1937.

SCARBOROUGH HOSPITAL.—The detailed plans for Scarborough's new hospital, which is to be built at a cost of over £100,000, are now available. The buildings are to be fireproof, and as far as possible soundproof. Advantage has been taken of a sheltered situation to have large sunny balconies and a solarium for the children. The hospital will have 140 beds, including a number for paying patients, and three operating theatres. The theatres have a ventilating plant which makes it possible to change the air or raise or lower the temperature very rapidly. The X ray therapy and light treatment departments and the massage and orthopædic rooms are on the ground floor and are connected by two bed lifts with the wards. The out-patients' department has a large waiting-room where there will be a refreshment counter, and a shelter for prams has also been provided. The dispensary is easily accessible both to the wards and to the out-patients' department. The kitchen is a self-contained unit and the food will be served from heated trolleys so that appetising and hot dishes may reach the most distant wards. The laundry and boiler room are also self-contained, and a supplementary electrical battery room will be able to provide current for the operating theatres and other parts of the institution if the municipal supply should fail. There are rooms for the visiting and administrative staff in the main building, and a separate home for the sisters and nurses.

OBITUARY

MICHAEL GEORGE FOSTER, M.D. Camb., F.R.C.P. Lond., O.B.E.

We regret to record the death of Dr. Michael Foster, the well-known authority on climatology, which occurred on Saturday last, June 16th, at Fincham, Norfolk, the home of his mother's family, after a short attack of pneumonia.

Michael George Foster was born in 1864 at Huntingdon, the only son and elder child of Sir Michael Foster, the famous Cambridge professor of physiology. Huntingdon was the private home of his father, while his grandfather, also a Michael, had been a surgeon in the same city. The childhood of the young Michael coincided with the remarkable development of the Cambridge science schools under his father, and he knew many who later became leading teachers as big boys.

DR. MICHAEL FOSTER

[*Photograph by Elliott & Fry*

Foster was educated at University College School, London, and Trinity College, Cambridge, and graduated with honours in the Natural Science Tripos in 1884. He entered Trinity too young to be a competitor for academic honours, but he acted as a junior demonstrator of physiology in the University. He proceeded for his medical education to University College Hospital, where he was a prizeman in surgery and in clinical medicine. He took the double English diploma in 1888, and the M.B. Cambridge in 1890, served as house surgeon, when post-graduate work in Vienna and Geneva followed. In 1891 he obtained the Swiss Federal Diploma.

At the very commencement of his professional career Foster showed most unmistakable signs of tubercle. He took two long sea voyages, but finally decided that he could not winter in England. This prevented him from seeking any official or hospital preferment in this country, and, after short sojourns at Maloja and Alassio, he proceeded to San Remo, where for many years he practised from November until May, returning to England for the warmer months. He built up a large practice in the Riviera, the outcome alike of sound clinical knowledge and sympathetic comprehension of the physical and mental make-up of a difficult order of patients, and soon attracted professional attention by his knowledge of the effects of climate on disease and by his early advocacy of open-air treatment of tuberculosis. On these subjects he collaborated with Hermann Weber in a contribution to Hale-White's text-book of Therapeutics, while in 1905 he contributed, also jointly with Weber, the section on climate and disease to Allbutt and Rolleston's System of Medicine. In this competent essay were set out the claims of the various climates of the world, and of Europe in particular, for restorative effects in many classes of disease, and the writers close with an exposition of the way to utilise home climates, a subject dear to Foster's heart, since his regard for our own shores was never dimmed by his long sojourns away from them.

Some twenty years ago he embarked upon spa practice in Harrogate, still alternating his residence during the cold months with San Remo. At Harrogate his medical and personal qualities continued to secure him the regard of patients and colleagues alike, but his practice at this period was interrupted by the war. He did good war service. At the outbreak of hostilities he became a temporary officer in the R.A.M.C., being attached to the 2nd Eastern General Hospital with the rank of Captain. Important work here upon cerebro-spinal fever attracted attention, and he was sent to the 55th General Hospital attached to the B.E.F. in 1917, with the rank of Major, while later, with the rank of Colonel, he became consulting physician to the Forces. He was twice mentioned in despatches and created O.B.E. To the Medical History of the War he contributed notes upon the occurrence of cerebro-spinal fever in 1916, in which year he was elected F.R.C.P.

Wherever Michael Foster was he collected practical information upon the treatment of diseases, as influenced by the effect of climate and the technique and amenities of treatment at health resorts. The result was a recently published book entitled the Baths and Medicinal Waters of Britain and Europe, a review of which appeared in our columns a few weeks ago. In this book brief descriptions are given of the different kinds of waters and baths and their uses, while a short survey is included of the principal British and European spas, the information being brought up to the present day. An important lesson to be learned from these pages is that some of the leading spas have begun to make certain courses of therapeutics into a specialty of the place, for it is now recognised that some such classification is needed both in the interests of patients and for the information of doctors.

In his later years Foster was the victim of osteoarthritis, and in 1931 he retired from practice as the result of increasing physical disability. He was the most uncomplaining of invalids, his sweet and charitable temper distinguishing him to the end as it had done throughout his career. He used his leisure to write the useful treatise referred to above, became actively interested in the International Society of Medical Hydrology, and as a member of the advisory committee of the British Health Resorts Association reported on many of the spas in this country despite his increasing lameness.

Foster was twice married. By his first wife, the daughter of Mr. R. Y. Shipley, C.B., he had three sons and one daughter.

HENRY WATSON SMITH, O.B.E., M.D. Aberd.

Dr. Watson Smith, medical director of the Lebanon Hospital for Mental Diseases, died suddenly of angina pectoris on June 12th, when on visit to this country on furlough. During his 25 years of office he had built up at Asfuriyeh, near Beirut, a mental hospital unique of its kind in the Near East. In the absence of any system of certification in Syria he had the chance of receiving many cases in the early stages of mental disorder, and patients travelled to consult him from Egypt, Iraq, Turkey, and Persia.

DR. WATSON SMITH

[Photograph by Abd. Beyrout

Henry Watson Smith was born in 1879 near Aberdeen, the son of a banker, but the influence of his uncle, Dr. C. J. Watson of Heigham Hall Asylum, Norwich, turned his thoughts towards the mental side of medicine. He qualified at Aberdeen with many honours in 1901, and held the usual house appointments, followed by posts of house surgeon at the West Suffolk hospital, and of second assistant officer at the Durham county mental hospital. In February, 1909, he went to Lebanon, having first obtained the Turkish medical degree at Constantinople. Later, he added to French a thorough working knowledge of Arabic.

Apart from his thesis on general paralysis, which gained him the M.D. Aberd. in 1912, Dr. Watson Smith has left little in print. The time that he could spare from clinical and administrative work was given up to teaching medical students at the (American) University of Beirut, where he was appointed professor of psychiatry and neurology in 1926. Regular classes at Beirut and at Asfuriyeh, six miles away, became compulsory for fifth-year students, and he was able to inculcate a grounding of sound mental medicine in men of all nationalities. Any who showed special interest came for a period of two months to work at the hospital and in the attached laboratory. The teaching side of this work was the more important since 35 years ago, when the hospital was founded, any thought or care for mental sufferers in Syria was simply non-existent, beyond the cruel rites of exorcism practised by religious fanatics.

In this result the personality of the director played a great part. His quiet and pleasant ways of dealing with people and affairs won him not only the trust and confidence of his patients and their friends and of the whole staff, but also the respect and goodwill of successive rulers of the country. In the campus of the American University he was a familiar figure, while his attachment to freemasonry brought him into contact with wider groups. He is said to have been the only British subject allowed to remain in Syria during the war, and had it not been for his representations the hill on which the hospital stands would have been used for gun emplacements. As it was, the site was respected by Jemel Pasha as a religious foundation. In 1917, Dr. Watson Smith was able to receive many of General Allenby's men at the hospital during a serious epidemic of influenza in recognition of which he received the O.B.E.

It was perhaps after this time that he began to show his special qualities as an administrator. Out of the meagre funds obtainable for some years from Europe and America, he contrived to restore and re-equip the buildings and develop the 36 acres of land, so that by 1924 the place was ripe for expansion. Pavilion after pavilion was built under his personal supervision, without architect or contractor, including a model steam laundry: an artesian well of 400 feet was successfully bored and a scheme of olive-planting, olive-pressing, and soap-making started. In November last, a new house for women was built entirely out of local funds, helped by capitation fees from the Franco-Syrian authorities for poor patients, and was opened by the president of the Lebanon Republic, who bestowed on Dr. Watson Smith the highest decoration given to a foreigner.

Dr. Watson Smith leaves a widow, and two sons, both of whom are studying medicine at Birmingham.

MEDICAL NEWS

University of Cambridge

At a congregation held on June 8th the honorary degree of master of arts was conferred on Sir Charles Martin, F.R.S., formerly director of the Lister Institute of Preventive Medicine.

Royal College of Surgeons of England

A meeting of the Council was held on June 14th, with Sir Holburt Waring, the president, in the chair. He announced the appointment of Prof. William Wright as Thomas Vicary lecturer for 1934.

The following appointments were made for the primary fellowship examination to be held at Dunedin in December: Prof. W. P. Gowland, assessor in anatomy; Prof. John Malcolm, assessor in physiology; and Mr. Herbert Chapman, superintendent of the examination.

Diplomas of fellowship were granted to the following candidates:—

G. F. Rowbotham, L.R.C.P., Manchester; N. L. Shepperd, M.B. Lond., King's Coll.; R. W. Doyle, M.B. Liverp.; William Buckley, L.R.C.P., Camb. and St. Bart.'s; W. A. Elliston, M.B. Camb., St. Bart.'s; G. K. McKee, L.R.C.P., St. Bart.'s; S. W. Holmes, M.B. Lond., St. Mary's; C. E. Markby, L.R.C.P., Camb. and St. Thomas's; J. K. Stanger, M.B. Durh.; R. J. Furlong, M.B. Lond., St. Thomas's; M. W. C. Oldfield, B.M. Oxon., Leeds; G. T. Partridge, M.B. Camb., St. Bart.'s; E. A. Devenish, M.B. Lond., Univ. Coll.; A. L. Eyre-Brook, M.B. Bristol, St. Bart.'s; R. S. Lewis, L.R.C.P., Camb. and St. George's; H. R. Thompson, M.B. Camb., London; H. F. Moseley, B.M. Oxon., St. Thomas's; H. J. B. Atkins, B.M. Oxon., Guy's; R. G. Pulvertaft, L.R.C.P., Camb. and St. Thomas's; Abbas Hilmy, L.R.C.P., Cairo and Guy's; K. S. Ayyar, L.R.C.P., Guy's and St. Bart.'s; D. B. McGavin, M.B. Camb., St. Bart.'s; J. R. Vald, L.R.C.P., St. Bart.'s; R. D. Ayyar, L.R.C.P., Madras and London; Satyanarayana, Sunkavally, L.R.C.P., Madras and London; F. N. Chenhall, M.B. Sydney; E. J. Collins, M.B. N.U. Irel., Dublin and London; J. V. Guinane, M.B. Sydney, St. Bart.'s; A. I. Hunter, M.B. N.Z., Otago; Sydney Krantz, M.B. Adelaide; J. P. F. Lloyd, M.B. Birm., St. Bart.'s; Andrew Logan, M.B. St. Andrews; C. J. Lord, M.B. Belf., London; S. B. Morris, M.B. N.Z., Otago; D. G. Radcliffe, M.B. Sydney, Otago; and E. B. Whittingham, M.B. Liverp., St. Bart.'s.

Diplomas of membership were granted to A. T. Roden (Bart.'s), H. C. Hugh (Bart.'s), and B. L. E. Wong (Guy's).

At the primary examination for the fellowship, from June 5th to the 16th, 197 candidates presented themselves, of whom 66 were approved and 131 were rejected. The following are the names and medical schools of the *successful candidates*:—

H. Ackers, M.R.C.S. Liverp.; H. Agar, M.B. Leeds, St. Mary's; H. R. Alban, Cardiff; M. Albert, Univ. Coll.; H. G. E. Arthure, M.R.C.S., Middlx.; J. I. M. Black, M.B., Durham; I. N. Blusger, M.R.C.S., Cape and St. Bart.'s; A. Bowen-Davies, M.R.C.S., Camb. and Guy's; W. Bullock, M.B. Liverp.; H. L. Cochrane, M.B. Belf., Univ. Coll.; L. Z. Cosin, M.R.C.S., Guy's; A. G. Cross, M.D. Camb., St. Mary's; H. L. Davies, M.B. Liverp.; I. H. Davies, Cardiff and Middlx.; H. K. Doctor, M.B. Bombay, St. Bart.'s; A. Dornan, M.B. Belf., Middlx.; Katherine W. Dunn-Pattison, Lond. Sch. Medicine for Women; B. H. Ellis, St. Bart.'s; J. S. Ellis, St. Thomas's; F. R. Edwards, M.B. Liverp.; R. H. Franklin, M.B. Lond., King's Coll. and St. Thomas's; S. G. French, M.B. Lond., Univ. Coll. and St. Mary's; H. W. C. Fuller, King's Coll.; Dorothy M. Gladwell, Lond. Sch. Medicine; H. Goldfarb, M.R.C.S., L.R.C.P., M.B. Lond., Univ. Coll.; D. L. Griffiths, M.B. Manch.; E. H. Hambly, St. Bart.'s; A. J. Heriot, King's Coll.; G. Hyman, M.B. Leeds, Middlx.; W. H. G. Jessop, M.B. Camb., Univ. Coll. and St. Mary's; H. H. Langston, M.B. Lond., St. Bart.'s; A. D. Le Vay, Univ. Coll.; J. W. S. H. Lindahl, B.Ch. Camb., St. Thomas's; C. J. Longland, St. Bart.'s; G. H. Macnab, M.B. Edin., King's Coll.; R. L. Mehra, M.B. Punjab, Univ. Coll. and Middlx.;

M. S. M. Mehta, M.B. Bombay, Guy's; D. V. Nadkarni, M.B. Bombay, Middlx.; M. L. Pan, M.B. Calcutta, St. Bart.'s; A. R. Parkes, M.B. Edin., St. Andrew's and Middlx.; E. R. G. Passe, M.R.C.S., London and Middlx.; E. W. Peet, M.B., Durham and Middlx.; G. L. Pett, St. Thomas's; J. W. Pugh, M.B. Oxon., Univ. Coll.; J. L. D. Roberts, St. Bart.'s; A. Rose, M.B. Dubl., Univ. Coll.; H. L. M. Roualle, St. Bart.'s; V. Sankarambal, Madras and Lond. Sch. Medicine; K. C. Sarkar, M.R.C.S. Calcutta, Guy's and King's Coll.; P. G. Scott, M.R.C.S., Camb. and St. Bart.'s; [illegible] nb., London; W. M. H. Shaw, Leeds; F. [illegible] Camb. and St. Bart.'s; J. Sherne, M.B. I [illegible] C. Spencer, M.R.C.S., London; J. A. Stallworthy, M.B. Otago, King's Coll.; R. Strang, M.B. Edin., Guy's; A [illegible] Otago and Univ. Coll.; T. G. [illegible] and Univ. Coll.; R. G. Ta[illegible] Townsley, M.B. Belf., Middlx. [illegible] Middlx.; M. G. Vatsalya, M.R [illegible] R. E. Waterston, M.B. Edin., King's Coll.; W. E. Wimberger, M.B. Birm., King's Coll.; and R. F. Winckworth, M.B. Lond., St. Thomas's.

The following were elected examiners for the ensuing year:—

Dental Surgery.—Surgical Section: Mr. Russell J. Howard, Mr. C. E. Shattock, Mr. C. P. G. Wakeley, Mr. P. H. Mitchiner, Mr [illegible] Vick. [illegible] Mr. J. Basil Hume, Mr. Gr [illegible] Taylor, and Mr. P. N. B. Odgers. Physiology: Prof. G. A. Buckmaster, Dr. D. H. de Souza, Prof. Samson Wright, and Prof. Hamilton Hartridge.

Diplomas of L.R.C.P., M.R.C.S.—Elementary Biology: Mr. T. J. Evans, Mr. G. P. Mudge, Mr. C. C. Hentschel, and Mr. A. J. Grove. Anatomy: Prof. W. E. Le Gros Clark, Prof. H. A. Harris, and Mr. E. P. Stibbe. Physiology: Dr. A. St. G. J. McC. Huggett, and Prof. Samson Wright. Midwifery: Mr. L. Carnac Rivett, Mr. Malcolm Donaldson, Mr. A. C. Palmer, and Mr. V. F. Lack. Pathology: Mr. C. E. Shattock, Mr. Robert Davies-Colley, Dr. R. G. Canti, and Prof. James McIntosh.

Diploma in Public Health.—Part I.: Prof. C. C. Okell. Part II.: Dr. James Fenton.

Diploma in Tropical Medicine and Hygiene.—Major-General D. S. Harvey and Dr. G. Carmichael Low.

Diploma in Ophthalmic Medicine and Surgery.—Part I.: Sir Stewart Duke-Elder and Mr. C. Bernard Goulden. Part II.: Mr. R. Foster Moore.

Diploma in Psychological [illegible] Greenfield.

Diploma in Laryngology [illegible]: Mr. E. Musgrave Woodman and Mr. [illegible]: Mr. T. B. Layton.

Diploma in Gynæcology and Obstetrics.—Mr. J. D. Barris.

Diploma in Medical Radiology.—Part I.: Prof. J. M. Woodburn Morison. Part II.: Dr. J. H. D. Webster.

University of Bristol

At recent examinations the following candidates were successful:—

M.D.

Herbert Rogers (with distinction), F. H. Bodman, J. J. J. Giraldi, and N. L. Price.

CH.M.

G. F. Langley (with distinction).

FINAL EXAMINATION FOR M.B., CH.B.

Part I. (including Forensic Medicine).—M. A. Nicholson and Broughton Ridgway.

Part II.—A. C. Molden (First Class Honours); A. G. W. [illegible] Derham, and C. H. G. Price (Second Class [illegible] Ball, Dorothy E. Barber, Violet Fry, [illegible] L. Gurney, T. R. V. Gurney, Gwladys Mathews.

Society of Medical Officers of Health

The Fever Hospital Medical Services Group of this society will hold their annual general meeting on Friday, June 29th, at 4 P.M., at the house of the society, 1, Upper Montague-street, London, W.C. Prof. Ulrich Friedemann, of the National Institute for Medical Research, who was formerly director of the infectious diseases department of the Rudolph Virchow Hospital, Berlin, will give a paper on malignant diphtheria with observations on cardiovascular failure and methods of treatment.

Conference on Vitamin Standardisation

In connection with the international conference on the standardisation of vitamins, which met in London last week under the auspices of the Health Committee of the League of Nations, Dr. J. O. Wakelin Barratt, the master, the wardens, and the court of assistants of the Worshipful Society of Apothecaries of London held a reception at their hall in Blackfriars on June 14th. Among those who attended the reception were:—

Dr. E. Mellanby, Medical Research Council; Prof. J. C. Drummond, University College; Prof. H. von Euler (Stockholm); Prof. L. S. Fridericia [illegible] B. C. P. Jansen (Amsterdam); Prof. P. [illegible] Dr. E. M. [illegible] (Paris); [illegible] -Gyorgyi [illegible] Geneva); [illegible] d [illegible] reventive [illegible] dingham, Director of the Lister [illegible] Coward, D.Sc.; Prof. A. Jung [illegible] Paris).

On June 13th Dr. W. D. R. Thompson (Inner Temple) and Dr. W. A. M. Stewart (Middle Temple) were called to the Bar.

London Association of Medical Women's Federation

A meeting will be held on Tuesday, June 26th, when Dr. Letitia Fairfield will speak on Eugenic Sterilisation of the Unfit, and Dr. C. P. Blacker will open the discussion. Members are invited to bring guests (men and women).

Hoffman Library for Cancer

Dr. Frederick L. Hoffman, jointly with the Prudential Insurance Company, has presented his library to the Cancer Research Laboratories of the University of Pennsylvania Graduate School of Medicine. The library includes not only a large number of books and reprints and journals on cancer, but also many related works and statistics and mortality data on cancer collected by the donor. Those who wish to deposit books or reprints in the library should address their publications to the Cancer Research Laboratories, University of Pennsylvania Graduate School of Medicine.

Harveian Society of London: the Buckston Browne Dinner

The banquet, offered to the Harveian Society of London annually, and founded by the life president of the Society, Sir Buckston Browne, was held at the Connaught Rooms, London, on Thursday, June 14th, when a large company assembled.

The Greek Minister proposed the health of the Society in fluent and amusing manner. He said that he would be short, and described an episode at a musical party at which he recently was present, when a distinguished composer rendered a composition of his own, which was understood to be a funeral march designed to accompany the transfer of his body from his home to the cemetery. A lady in the audience, finding the composition over-long, remarked, "Dear Maestro, you live too far away from the cemetery." M. Caclamanos said that for this occasion he was living near the cemetery, adding that he could think of only one reason why the toast had been confided to him—namely, that he could read Hippocrates in the original. Yet, he said, he had played once an important medical rôle, for as a young secretary at the Greek legation in Paris he had this singular experience. There was an international sanitary conference in Paris, and the Greek delegate, a distinguished hygienist, having fallen suddenly sick, a peremptory telegram from Athens commanded him to attend the conference as a substitute. "Not only," said his Excellency, "did I represent my Government, but I took part in the discussions, and I signed an important technical convention by which, as far as I can remember, all dreadful diseases were to be expelled from European shores." Proceeding in serious vein, M. Caclamanos declared that always universal admiration would be felt for Harvey; while ancient Greeks had said that there is nothing new under the skies, and while they had discovered so much of the fundamentals of science, they had left it to an Englishman to explain the problem of the circulation of the blood. A part of the story had been guessed by them, and scientists of other nationalities had thrown out views, but, said His Excellency, it was left to your great citizen to really describe the circulation of the blood and to prove his thesis beyond dispute. M. Caclamanos closed by congratulating the Society on entering the second century of its existence.

Sir Buckston Browne, replying to the toast, said that the Society was in a prosperous position, having a membership of 400, while the institution of a prize essay had led to excellent discussions, proving the value of societies, such as the Harveian, in promoting professional intercourse. This, he said, was a truth which the great Harvey himself would have well understood. Darwin, he continued, had changed the whole position of medicine when he showed that the human body was the finest product of evolution, and it was the great duty of the medical profession to keep the machinery of that body in working order.

Mr. Dickson Wright proposed the health of the visitors, to which Dr. F. M. R. Walshe, the Harveian Lecturer, and Mr. F. R. Mortimer, Master of the Worshipful Company of Barbers, responded.

British Homœopathic Society

Dr. O. Leeser, of Stuttgart, is giving an address on "Constitution and Constitutional Treatment" at the London Homœopathic Hospital, Queen-square, W.C., on Thursday, June 28th, at 5.30 P.M., to which all medical men and women are invited.

International Congress of Radiology

The fourth international congress of radiology will be held at Zurich and St. Moritz from July 24th to 31st. Members who wish to avail themselves of any of the special itineraries and inclusive fares arranged are asked to inform the general secretary of the British Institute of Radiology, 32, Welbeck-street, London, W.1, without delay.

Women Smokers in Hospital

Liverpool city council has referred back a recommendation of the hospitals committee that smoking by women patients should not be allowed. It was stated that some women who had been smoking surreptitiously put their cigarettes under the bedclothes when the nurses appeared, with obvious danger of fire. The reference back was carried by a large majority.

Birmingham Skin Hospital

Colonel W. F. Wyley, Provincial Grand Master of Warwickshire, recently laid with masonic rites the foundation-stone of the new in-patient department of the Birmingham and Midland Skin Hospital in George-road, Edgbaston. Last year 80,000 out-patients and over 400 in-patients were treated. When the new building is completed, the old building in John Bright-street will be devoted entirely to out-patient work.

Sanitation at the Hull Airport

The Town Clerk of Hull recently addressed a letter to the Minister of Health asking for extension of the competence of the borough sanitary authority, so as to carry out medical inspection of aliens arriving at the local aerodrome. In his reply, the Minister of Health, while pointing out that the airport lies outside the jurisdiction of the city council and of the port sanitary authority, agrees to extend the present warrants of the medical officers for that purpose.

British Health Resorts Association

A conference is being held by this association at Cromer and Sheringham next week-end, from June 29th to July 1st, with two main subjects for consideration. Dr. R. A. Young, physician to the Middlesex and Brompton Hospitals, will open a discussion on the seaside resort in the treatment of respiratory diseases, other speakers on this theme being Dr. L. S. Burrell and Dr. A. J. Morland. A discussion on the climatic and allied factors in the incidence of disease and its treatment on the East Anglian coast will be opened by Dr. R. Fortescue Fox, followed by Dr. F. W. Burton-Fanning, Dr. Wilfred Pearson, and Mr. L. C. S. Bonacina, of the Royal Meteorological Society. The secretary of the association may be addressed at 199, Piccadilly, London, W.1.

Rockefeller Medical Fellowships

The Medical Research Council announce that, on behalf of the Rockefeller Foundation, they have made the following awards of travelling fellowships for the academic year 1934–35. Ian Aird, M.B. Edin., department of anatomy, University of Edinburgh; Ian Alfred Anderson, B.Sc., M.B. Aberd., Royal Infirmary, Aberdeen; Eric Gordon Oastler, M.B. Glasg., St. Mungo's College, Glasgow; Wilfred Harding Owles, B.Sc., B.M. Oxon., Queen's Hospital, Birmingham; Harold Leeming Sheehan, M.Sc., M.D. Manch., department of pathology, University of Manchester; and Clifford Wilson, B.M. Oxon., department of pathology, London Hospital. These fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine, or in clinical medicine or surgery, and who are likely to profit by a period of work abroad before taking up positions for higher teaching or research in the British Isles. All the fellows appointed this year will work at centres in the United States.

Epsom College

The following Foundationers were elected by the conjoint committee on June 13th: Daniel L. C. Thomas, William Farquhar Graham, John Urquhart Crichton, Colin C. R. Walker, Francis McLean Mathewson, Ian Young, and Donald M. Simmins. Denis M. W. Hartley was also elected as a special Foundationer. The following were elected Pensioners: Mrs. Grace Elizabeth Hutchinson and Mrs. Alice M. A. Cockell.

Brentwood District Hospital

This new hospital was opened last week by Princess Helena Victoria. A site of 18 acres was given by Mr. Percy Bayman, and the building has cost £40,000, the whole of which has been subscribed. It was designed to provide 100 beds; at present there are 40.

East Suffolk and Ipswich Hospital

Lord Moynihan last week opened a new block of private wards containing 30 single-bed wards and 4 six- or four-bed wards. In his speech Lord Moynihan emphasised the fact that the income of the voluntary hospitals of the country now exceeded their expenditure.

Putney Hospital for Incurables

At the festival dinner last week of the Royal Hospital and Home for Incurables, Putney, it was stated that the institution has 250 inmates, and a pension list of 600. The cost of maintenance and pensions is £40,000 per annum. Owing to an abnormal number of bequests the year 1933 was "extraordinarily good."

Royal Salop Infirmary

The annual report states that last year there were 2080 in-patients, a small increase, and 9257 out-patients, an increase of nearly 800. The facilities for treating surgical cases are rapidly becoming inadequate, and the one general theatre has been in use for practically a 24-hour day throughout the year.

Lady Tata Memorial Scholarships

The trustees of the Lady Tata Memorial Trust announce that on the recommendation of the scientific advisory committee, they have made their awards of scholarships for the year 1934–35. These scholarships were open to graduates of any nationality for research work in diseases of the blood, with special reference to leukæmia. The recipients are: Dr. W. Büngeler (Danzig), Dr. L. Doljanski (Copenhagen), Dr. M. C. G. Israels (Manchester), Dr. C. Oberling (Paris). Dr. J. Engelbreth-Holm (Copenhagen), Dr. M. O. K. Jorgensen (Aarhus, Jutland, Denmark), Dr. R. Meier (Leipzig), and Dr. Lucy Wills (London).

Pay-Beds at London Hospital

At the quarterly court of the governors of the London Hospital last week the house committee reported that King Edward's Fund had approved of the proposal to establish pay-beds for patients of moderate means. The scheme involves the adaptation of the three top floors of the block in Newark-street, but by putting into use rooms elsewhere, hitherto unoccupied, and by various readjustments the number of beds available for the poor will not be diminished to any appreciable extent. The scheme will provide 44 beds and cubicles; the charges will be moderate, and as far as possible inclusive, and the specialists' fees will be reduced to meet the patient's circumstances. The cost of adaptation and of building an operating theatre will be about £10,000, and since the general hospital funds cannot be used for the purpose an appeal for this sum is to be issued.

A REPUDIATION.—Dr. A. J. Byrne asks us to say that he gave no consent to the publication of a recent paragraph in the *Guardian*, communicated by a patient and expressing her appreciation of his treatment. He is advised by the Medical Defence Union to ask publicity for this repudiation.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Hospitals and Treatment of Road Accidents

WHEN the Road Traffic Bill was further considered by a Standing Committee of the House of Commons on June 14th. Mr. STOREY moved a new clause providing for the payment for hospital treatment of road accidents other than emergency treatment up to a maximum of £50 for in-patients and £5 for out-patients, irrespective of the question of negligence.

A REASONED PLEA FOR COMPENSATION

It was, said Mr. Storey, the logical conclusion of the emergency treatment clause already passed. If it was right to pay for emergency treatment given by hospitals, then it was even more right that treatment which might cost the hospitals tens and even hundreds of pounds should be met in this way.

It might, he said, be objected that this clause and the emergency treatment clause attributed the whole fault of accidents to the motorists. He submitted that they did nothing of the sort. Accidents were not due to the fault of motorists but to the fact that there were motors on the roads. This clause provided that the cost of treatment due to the fact of motors should be borne not by the hospital or the patient, who were not responsible for the change in conditions, but by the motorist who was responsible for the change. It did, however, give to the motorist, where it could be proved that some other party was directly responsible for the accident, the right of recovery. The compulsory insurance clauses of the Road Traffic Acts provided a means by which the cost of such treatment could be met without any appreciable burden on individual motorists; they provided a means by which payment for that treatment could be distributed among the hospitals rendering the treatment and they might also provide the means by which these matters could be handled by those who were most experienced in dealing with them.

Road accidents cost the hospitals some £180,000 per annum. With the limit of £50 proposed in this clause the amount recovered would not amount to anything like that sum, but even if the whole cost were recovered, it would work out at only 1s. 7*d*. per head to the motorists. That was a very small contribution to ask from motorists to the hospitals. He did not believe after a good deal of experience in collecting money for hospitals that if these provisions were passed hospitals would lose a penny piece in subscriptions.

Not only among the hospitals, but among the subscribers, particularly the workmen subscribers, there was at present a real feeling of hardship. They said that the money raised by them to treat the sick in their district was being used to treat road accident cases, the cost of which they held should be met from other sources. Under the 1933 Act something was done for the hospitals, but it was very little. Representatives of the hospitals had put forward their solution, and if the Minister would not accept it, would he suggest an alternative?

Sir FRANCIS FREMANTLE said what most of his friends were keen on was to get this hardship to the voluntary hospitals put right. There was a strong feeling on this subject throughout the country which had resulted in this clause. He hoped that the Minister of Transport would show that if he had not an alternative ready to hand he was prepared to help representatives of the hospitals to find a solution.

Sir ERNEST GRAHAM-LITTLE said the request for this clause came from all the authoritative bodies which dealt with hospitals. What the hospitals undertook was not merely emergency treatment. It was the specially difficult and important cases that went to the hospitals which entailed in the great majority of cases a long period of treatment.

THE MINISTER'S REPLY

Mr. OLIVER STANLEY objected to putting the motor owner in a selected position as almost the only class in the country to be responsible for an act which was not in any way negligent and which indeed might be caused by the negligence of someone else. He wondered whether the clause was really in the best interests of the hospitals themselves. He dismissed at once as, taking the hospitals as a whole, grossly unfair the argument that motors had created this new situation, that it was the coming of the motor which had put this responsibility upon hospitals, and therefore it must be the motor owner who paid. They could not take that sort of debit side of the invention of the internal combustion engine without looking at the credit side also. He felt that to the ordinary subscribers to hospitals, such as himself, this meant the end of the voluntary hospital system as he had always understood it. It was now proposed that they should adopt a new principle and that they should be taxed—for that was what it amounted to—to provide for the care of certain unfortunate injured people if their injury arose in a special way. He thought that such an idea would lead many subscribers to hospitals in the future to limit their subscriptions to hospitals to whatever return those institutions might give to them. Had there ever been an attempt by the hospitals as a whole to try with the help of motoring organisations and motorists generally to set up a central fund from which relief could be given? [Mr. TURTON said that had been done in Yorkshire.] He believed that not only would the immediate result of such an appeal be better from the point of view of the hospitals, but that taking the long view their future would be much more assured.

Mr. STOREY said that the alternative offered, a corporate appeal to motorists, had already been tried and had not proved particularly successful. He had no reason to think that a general appeal all over the country would be any more successful. He appealed to the Minister to try to get the motorists, insurance companies, and the hospitals together.

Mr. STANLEY said he gladly responded to this suggestion.

The clause was negatived by 21 votes to 6, and this concluded the committee stage of the Bill.

HOUSE OF COMMONS

WEDNESDAY, JUNE 13TH

Naval Cadets and Defective Vision

Mr. SAVERY asked the First Lord of the Admiralty the number of cadets who, during the last three years, had been compelled to withdraw from Dartmouth Naval College on account of defective vision.—Sir BOLTON EYRES-MONSELL replied: During the last three years seven cadets have been required to withdraw from the Royal Naval College, Dartmouth, on account of defects of vision. Of these, one had been offered a transfer to the engineering branch and five to the accountant branch, but these transfers had been declined. The seventh was unfit for service in any branch.

Blackheath Hospitals and Electric Light Failure

Mr. THORNE asked the Minister of Transport whether he had received a report from his inspectors relative to the inconvenience caused to the hospitals in the Blackheath area when the electric light supply failed for a number of hours on Sunday night; if he was aware that the hospitals had no electric light supply for three hours; and if he could state the cause of the breakdown.—Mr. STANLEY replied: I am informed that the breakdown was due to a fault on an old distributor which had been in service for many years; that the principal inconvenience was suffered by the Herbert Hospital; and that the hospital has now been connected to a new ring main which the company were laying to provide additional security of supply and which was on the point of completion when the breakdown occurred.

Cheap Milk-supplies in Glasgow

Mr. KIRKWOOD asked the Secretary of State for Scotland what contract was signed by the Glasgow milk retailers who had been refused supplies by the Milk Board because they sold standard milk to working-class consumers at cheap rates; and, if no contracts were signed by these retailers, why were they prohibited from selling milk at the lowest possible price to consumers.—Sir GODFREY COLLINS replied: Under the contract entered into between distributors and the Scottish Milk Marketing Board it is provided that all buyers of milk from or through the agency of the Board shall undertake to observe the prices fixed by the Board and to take subpurchasers bound in a similar obligation. The retailers referred to are subpurchasers in terms of the contract.

Malaria in Bechuanaland

Mr. LUNN asked the Secretary of State for Dominion Affairs whether he could give any information on the outbreak of malaria in Bechuanaland; whether he was aware that at Ghanzi there had been 250 deaths following a period of starvation; and what measures His Majesty's Government was taking.—Mr. THOMAS replied: I regret to say that there has been an outbreak of malaria in certain districts of the Bechuanaland Protectorate. I have not yet received any detailed reports from the High Commissioner for South Africa as to mortality, but I have no doubt that these will be forthcoming as soon as the information is available. Prompt measures have been taken by the local administration to deal with the outbreak by sending medical officers and the necessary supplies of quinine to the districts affected. I may add that provision was made last year and has again been made this year for the relief of distress unfortunately occasioned in the Protectorate by the late disastrous drought in South Africa.

Butter and Margarine in Pensions Hospitals

Mr. HAMER RUSSELL asked the Minister of Pensions if he was aware that margarine was issued normally to all patients in the Ministry of Pensions hospitals; and if, having regard to the surplus milk in the country, he would issue instructions for butter to be used in place of margarine.—Major TRYON replied: Butter is always supplied to patients in Ministry hospitals if medically recommended, but otherwise the practice in Ministry hospitals has in the past followed that of the majority of similar institutions. But I am going into this matter with a view to making a change.

Mr. MACQUISTEN: Is the Minister aware that certain qualities of margarine have the same qualities as cod-liver oil and are much better for patients than ordinary butter?

No answer was given.

THURSDAY, JUNE 14TH

Silicosis

Mr. JOHN asked the Home Secretary whether he had received a reply from the Mining Association on the subject of silicosis; and whether he was now in a position to review the arrangements in force under the present scheme.—Sir JOHN GILMOUR replied: As the result of the conferences which have recently taken place, I am expecting to receive next week from the Mining Association certain proposals which they desire to submit with a view to remedying the position. I should then be able to review the existing arrangements, and the hon. Member may be assured that every effort will be made to reach an early decision.

Imported Milk Products and Public Health

Lieut.-Colonel WINDSOR-CLIVE asked the Minister of Health what precautions he was taking to ensure that all dairy products imported into this country were produced under the same sanitary conditions as were imposed on similar products produced here.—Sir HILTON YOUNG replied: Imported milk is subject to special bacteriological conditions which do not apply to home-produced milk. In addition all imported articles of food are subject to examination at the port of entry to ensure that they are not diseased or otherwise unfit for human consumption.

Nursery Schools

Viscountess ASTOR asked the Parliamentary Secretary to the Board of Education what local education authorities submitted plans for new nursery schools during 1931; and which of these were refused by the Board of Education on account of the economy cuts.—Mr. HERWALD RAMSBOTHAM replied: Eleven local education authorities submitted proposals for new nursery schools during 1931. In the case of seven of these approval of the proposal was withheld on account of the financial circumstances, but one has since been allowed to proceed.

Viscountess ASTOR: Would the hon. gentleman promise the House that now the financial circumstances are better he will give the local authorities permission to establish these schools?

Mr. RAMSBOTHAM: That must depend on the urgency of the circumstances.

Underground Rooms in London

Major NATHAN asked the Minister of Health whether he had now obtained any particulars from the London County Council as to the number of underground rooms habitually used as sleeping places in the administrative County of London that were unfit for human habitation within the meaning of Section 18 of the Housing Act, 1925.—Sir HILTON YOUNG replied: Yes, sir. I understand that the returns being obtained by the London County Council are still incomplete, but those received up to date show 7186 rooms within the description used by the hon. Member.

Water-supplies in Scotland

Lord SCONE asked the Secretary of State for Scotland the present position in regard to the shortage of water in Scotland in general and in the counties of Perth and Dumfries in particular.—Mr. SKELTON (Under-Secretary of State for Scotland) replied: No reports of the existence of any special emergency arising from a shortage of water due to drought have been received from any local authority. The information of the Department of Health is that, thanks to the rains this spring, the areas that suffered a shortage in the spring and autumn of last year are at the present moment adequately supplied. It is known, however, that supplies in certain localities are under ordinary conditions inadequate and the department are at present receiving from local authorities applications for grant under the Rural Water Supplies Act, 1934, to assist in providing supplies or in improving existing supplies.

MONDAY, JUNE 18TH

Veterinary Inspection of Cattle

Mr. THOMAS WILLIAMS asked the Minister of Agriculture how many qualified veterinary surgeons were employed by his department exclusively for inspecting cattle, and farm sheds and buildings, and other duties involved in the Tuberculosis Order, 1925; and how many inspections were carried out during the last year for which figures were available.—Mr. ELLIOT replied: There are no qualified veterinary surgeons employed by the Ministry exclusively on duties involved under the Tuberculosis Order, 1925, which, in the main, is administered by the local authorities and their veterinary staffs. Imported cattle are examined in the landing place by the Ministry's veterinary staff for tuberculosis as well as for other scheduled contagious diseases, and on this work 11 veterinary inspectors are employed full time.

Gas Attack Lectures in Scotland

Mr. KIRKWOOD asked the Secretary of State for Scotland under what authority Army officers had been giving private lectures in Maryhill Barracks, Glasgow, to members of the Red Cross and Voluntary Aid Detachment on how to deal with victims of gas attacks from the air; if similar lectures were being given in other parts of Scotland; and, if so, were these part of an official scheme to prepare for war in the air.—Mr. DUFF COOPER (Financial Secretary to the War Office) replied: Training in defence measures against gas attacks, whether from the air or otherwise, is part of the normal training of the Army. The Voluntary Aid Detachments provided by the British Red Cross Society undertake to assist the medical services of the Army should they be required in time of emergency, and measures of protection in gas warfare form part of the training given to these detachments. Army officers are accordingly allowed to assist this training by giving lectures.

Safety Glass in Taxi-cabs

Sir ASSHETON POWNALL asked the Home Secretary if he would make the use of safety glass obligatory for all taximeter-cabs licensed in future.—Sir J. GILMOUR replied:

The requirement as to the fitting of safety glass is the same for taxicabs as for other motor vehicles—namely, that vehicles registered after Jan. 1st, 1932, must have safety glass fitted to windscreens or windows facing to the front on the outside, and that vehicles registered before that date must be so fitted before Jan. 1st, 1937. *It is not proposed at the moment to make any additional requirements for cabs.* Most of the new cabs presented for licensing in London are, however, fitted with safety glass throughout.

TUESDAY, JUNE 19TH

Gas Detectors in Mines

Mr. TOM SMITH asked the Secretary for Mines if he could make a statement with regard to the suggested regulation for the compulsory use of gas detectors underground.—Mr. E. BROWN replied : It is an essential condition of effective action in this matter that the workmen individually and through their organisations shall coöperate willingly and actively to give effect to any regulations that may be made. Otherwise the regulations would be ineffective. The reasons why this is so were fully stated in the unanimous report made some years ago by a representative committee—the Miners' Lamp Committee—and they are reasons which hold good to-day. In these *circumstances it is of the first importance that I should, if* possible, find a basis of action by agreement with the workers' representatives, and I propose to invite them to a further discussion of the objections they now feel to the proposals put forward by me.

Collections for Charities

Mr. OSWALD LEWIS asked the Home Secretary if he had yet come to a decision as to whether there was any action that he could usefully take for the better control of house-to-house collections and collections in such places as shop arcades and railway stations for charitable purposes in the Metropolitan police district; and, in particular, whether he would make it obligatory for all persons taking part in such collections to have a permit from the police as recommended int the Report of the Advisory Committee on Street Collections for 1933.—Sir J. GILMOUR replied : Since my hon. friend asked me a question on the same subject in April, I have given the matter my careful consideration. As he is probably aware, the Departmental Committee on the Supervision of Charities, which reported in March, 1927, recommended, among other things, that a system of licensing for door-to-door collections should be introduced, and this proposal was included in the Collecting Charities (Regulation) Bill which was introduced by the Government in 1929. This particular proposal, however, met with great opposition and the Bill was not proceeded with. In the absence of any reason to suppose that there has been a material change of feeling, I do not see my way to introduce fresh legislation for the purpose, and in any case there would be no opportunity for legislation this session.

Vacancies

For further information refer to the advertisement columns

Aberdeen University.—Lecturer in Morbid Anatomy. £400.

Accrington Victoria Hospital.—H.S. £150.

Birmingham Children's Hospital.—Res. M.O. £175.

Birmingham City.—P.H. Dept., Sen. Asst. M.O. for Tuberculosis Section. £750.

Birmingham City Education Committee.—Temporary Asst. School M.O. At rate of £500.

Bolton Royal Infirmary.—H.P. £200.

Brentwood, Essex, Highwood Hospital.—H.P. At rate of £80.

Bristol Eye Hospital.—Asst. Res. H.S. At rate of £100.

Cardiff, University College of South Wales and Monmouthshire.—Asst. Lecturer in Anatomy. £400. Asst. Lecturer in Physiology. £400. Asst. Lecturer in Histology. £300.

Central London Ophthalmic Hospital, Judd-street, W.C.—Sen. and Jun. H.S.'s. £120 and £100 respectively.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Assts. for Out-patients' Dept.

Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £150.

Connaught Hospital, Walthamstow, E.—H.P. At rate of £100.

Dagenham Urban District Council.—M.O.H. £900.

Dublin, Ministry of Pensions Hospital, Leopardstown Park.—Asst. M.O. At rate of £285.

Durham County Hospital.—Two H.S.'s. Each £150.

East Ham Memorial Hospital, Shrewsbury-road, E.—Hon. Ophth. Surgeon.

Exeter, Royal Devon and Exeter Hospital.—H.S., Ear, Nose and Throat Dept. At rate of £150.

Folkestone Royal Victoria Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £150 and £120 respectively.

Gloucestershire Royal Infirmary, &c.—H.P. and H.S. Each at rate of £150.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. At rate of £50.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. At rate of £100.

Huddersfield Royal Infirmary.—H.S. At rate of £150.

Hull Royal Infirmary.—Third H.S. At rate of £150. Hon. Radiologist. Also Cas. O. At rate of £150.

Ilford, King George Hospital.—Cas. O. and H.S. At rate of £130 and £1[illegible]

Indian Me[illegible]

King's Col[illegible] *S.E.*—Hon. Radiologist.

Lincoln Co[illegible] At rate of £150.

Liverpool, [illegible] -Res. Asst. M.O. £200.

London Lock Hospital, 91, Dean-street, W.—Surg. Reg. £100.

London (R.F.H.) School of Medicine for Women, Hunter-street, W.C.—A. M. Bird Post-grad. Scholarship. £200.

London University.—Examinerships.

Maidstone, West Kent General Hospital.—H.P. £150.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. M.O. for St. Anne's Home. £200.

Manchester Northern Hospital for Women and Children, Park-place.—Jun. H.S. £100.

Manchester Royal Children's Hospital.—Res. M.O. At rate of £125.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Metropolitan Hospital, Kingsland-road, E.—Cas. O. At rate of £100.

Middlesex County Council.—Tuberculosis M.O. £750.

Miller General Hospital, Greenwich-road, S.E.—Cas. O. At rate of £150.

National Temperance Hospital, Hampstead, N.W.—Hon. Asst. Surgeon.

Newcastle-upon-Tyne Hospital for Sick Children.—Res. Surg. O. £250.

New Zealand, Wellington Hospital Board.—Superintendent. £1100. Also Res. Surg. O. £400

Norwich, Norfolk and Norwich Hospital.—H.S. to Spec. Depts. £120.

Nottingham Children's Hospital.—Res. H.S. At rate of £150.

Rochester, St. Bartholomew's Hospital.—H.S. At rate of £175.

Royal College of Surgeons of England.—Pathological Curator of the Museum.

Royal London Ophthalmic Hospital, City-road, E.C.—Refraction Asst. to L.C.C. School Dept. £160.

St. Alfege's Hospital, Vanbrugh Hill, Greenwich, S.E.—Asst. M.O. £350.

St. Bartholomew's Hospital, E.C.—Chief Asst. to X Ray Diagnostic Dept.

St. Charles' Hospital, Ladbroke-grove, W.—Asst. M.O. £250.

Salisbury General Infirmary.—H.S. and H.P. Cas. O. Each at rate of £125.

Scarborough Hospital and Dispensary.—H.S. At rate of £175.

Sheffield Children's Hospital.—H.S. Also H.P. Each at rate of £100.

Sheffield Royal Infirmary.—M.O. to Assist Medical Director at Sheffield Radium Centre.

Singapore, Straits Settlement, King Edward VII. College of Medicine.—Prof. of Surgery. £1190.

Southampton, Free Eye Hospital.—Locum Tenens Ophth. S.H. Six gns. per week.

Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200.

Southend Municipal Hospital, Rochford.—Asst. M.O. £275.

Southend-on-Sea General Hospital.—H.S. At rate of £100.

Stockport Infirmary.—H.S. £150.

Surrey County Mental Hospital Service.—Jun. Asst. M.O. £350.

Tunbridge Wells, New Kent and Sussex Hospital.—Res. Surg. O. £250. Sen. H.S. £175. Second H.S. £150. Also Jun. H.S. £125.

Willesden Corporation, Health Dept.—Dental Surgeon. £600.

Wolverhampton Royal Hospital.—H.P. At rate of £125. Also Asst. Res. M.O. and H.S. to Spec. Depts. Each at rate of £100.

Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—H.P. and H.S. Each at rate of £100.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at East Kilbride, Lanark.

Appointments

ANDERSON [illegible] M.R.C.S. Eng., [illegible] Glasgow Royal [illegible] hemistry to the University of Glasgow.

ARTHURE, H. J. E., M.B., B.S. Lond., House Surgeon at the Chelsea Hospital for Women.

GRAHAM BRYCE, A., M.D. Manch., F.R.C.S. Eng., Honorary Assistant Surgeon to the Manchester Royal Infirmary.

MARTIN, J. PURDON, M.D., F.R.C.P., Honorary Assistant Physician to the Royal London Ophthalmic Hospital (Moorfields Eye Hospital).

MOIR, P. J., M.C., M.B. Glasg., F.R.C.S. Eng., Hon. Surgeon to the General Infirmary, Leeds.

O'REILLY, J. N., B.M. Oxon., M.R.C.P. Lond., Hon. Physician to the Royal Waterloo Hospital for Children and Women.

SMITH, R. R., L.R.C.P. Lond., M.R.C.S., Medical Referee under the Workmen's Compensation Act for Birkenhead, &c. (Circuit 7).

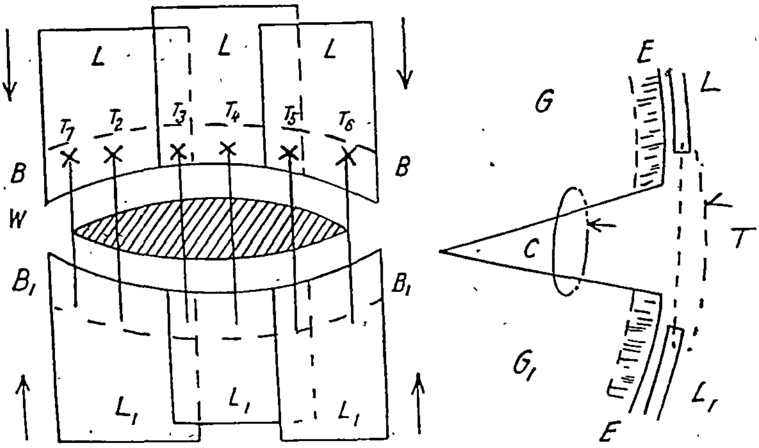
TURNER, Beatrice, M.B. Lond., F.R.C.S. Edin., Junior Obstetric Surgeon to the Elizabeth Garrett Anderson Hospital.

NOTES, COMMENTS, AND ABSTRACTS

CUTANEOUS WOUNDS JOINED WITHOUT SUTURE

To obviate the disadvantage, in joining the edges of a wound, of making a series of new puncture wounds for the passage of the threads, Dr. **Ejnar Dujardin**, of Copenhagen, proposes the following method, which he has practised successfully.

At a distance of about 1 cm. from the edges of the wound (W) slips of adhesive plaster (L–L_1) are attached to the skin, their borders being shaped according to the shape of the wound. A narrow border (B–B_1) of the plaster strips is left unattached to the skin, and through these free borders silk threads (T_1–T_6) are sewn from slip (L) to slip (L_1). The borders are then stuck together (B to B_1) and on tightening and knotting the threads the wound edges are carefully approximated. Care must be taken that the adhesive plaster slips are placed in such a way that the pull is longitudinal and not transverse. If the wound is particularly deep the tension may be reduced by applying through the subcutaneous tissue (G–G_1) ring-shaped countersunk catgut sutures (C) which do not touch the epidermis (E) and which are tightened and knotted before sticking the adhesive plaster slips together. Dr. Dujardin says that this method, apart from the good result from a cosmetic point of view, has the advantage of being painless.



Diagrams illustrating the closure of wounds without suture by Dr. Dujardin's method.

LEPERS IN MALAYA

Every leper in Malaya is required by law to be segregated, and this law is strictly enforced. With the object of providing model conditions of housing, control, and treatment, the Government of the Federated Malay States opened in 1930 a free leper settlement at Sungei Buloh, 12 miles north-east of Kuala Lumpur, an account[1] of which has been prepared for publication by Dr. G. A. Ryrie, the medical superintendent. The settlement, which covers 57 acres, has accommodation for about 1000 lepers, who are housed in 13 large wards and some 150 separate dwelling houses. There is a school for 80 children, hospital wards are provided for advanced cases and for the sick, and out-patient buildings for examination and treatment of ambulatory inmates. All patients, except a few patently beyond aid, receive regular treatment, and they are encouraged to look forward to ultimate discharge, which is permitted when they have been clinically and bacteriologically free from symptoms for six months. Dietetic, biochemical, and serological experiments, and investigation into the action of new drugs, are carried out with the aid of two volunteer groups kept under ward supervision.

An interesting feature of the settlement is the endeavour to control the lepers without any coercion, physical or mental. Dr. Ryrie says: "The settlement is not on an island; there is no wall—only a demarcating wire fence—and any of these legally detained patients could escape if they wanted to. There are no outside guards or police, and the settlement is only a mile from the main road to the capital. In spite of this, very few ever attempt to escape, and most of these return voluntarily in a short time." This is effected by giving the patients responsibility and a share in the management of the institution, by providing them with plenty of suitable occupation and recreation, and by surrounding them with an atmosphere of fairness and naturalness. Four shops managed by the inmates are subject to only two restrictions—that no opium or alcohol is on sale, and that nothing but metal money, which can be easily sterilised, may pass as currency.

Married quarters are supplied in each section. The birth-rate is low, and, as no child is ever born with leprosy, those born in the settlement are protected by being removed at the age of two weeks to the general hospital in Kuala Lumpur, where they are cared for at Government expense. When parents are discharged from the settlement their children are returned to them; others are adopted. The work of the settlement is undoubtedly an advance in international endeavour to secure suitable conditions and adequate treatment for lepers, and when it is realised that the patients are of many different nationalities and at least half a dozen religions, it says much for the methods employed that administrative trouble is avoided and that a courteous and cheerful atmosphere prevails.

TRAINED NURSES FOR PATIENTS OF SMALL MEANS

The chairman of committee of the Nursing Sisters' Institution, 10, Collingham-road, London, S.W.5, calls our attention to the facilities provided by this institution. It was founded by Mrs. Elizabeth Fry, in 1840, for providing fully trained nurses at a reduced fee for those of small means. All members of the staff are fully trained State-registered nurses and are fully competent to undertake the nursing of all acute cases of illness: those sent to maternity patients hold, in addition to their certificate for general training, the certificate of the C.M.B. The fees charged are from £2 12*s.* 6*d.* per week, and a billeting fee of £1 1*s.* to £1 10*s.* is charged for boarding out nurses who cannot be accommodated in the patient's home. Our readers will be glad to have the address of the institution for the benefit of patients unable to afford the full fees for the services of a private nurse. Further particulars may be obtained from the lady superintendent at the institution.

LONDON OUT-PATIENT TIME-TABLE

King Edward's Hospital Fund has brought out a new edition, revised to May, 1934, of a hospital out-patient time-table, setting out the hours at which medical, surgical, and other special cases are dealt with at the voluntary hospitals within the radius of 11 miles from St. Paul's. The time-table should be of assistance not only to the various social agencies, which often make the actual arrangements for attendance, but especially to the general practitioners who may wish to send their patients for consultations. The information should help to prevent the fruitless waiting which occurs when patients attend out-patient departments at the wrong hour or even on the wrong day. The time-table, which can either be kept folded as an octavo booklet or unfolded in quarto form and inserted in a telephone directory, may be obtained free of charge from Messrs. Geo. Barber and Son, Ltd., Furnival-street, E.C.4.

HEALTH IN PREGNANCY

Nobody is more avid of good advice than the expectant mother, and nobody receives more of it, verbally from her next-door neighbour, and in print from the daily press. Since teaching from such a reliable source as the head of a unit of obstetric medicine in the University of London enters the lists at the competitive price of only 6*d.*[1] there is no excuse for not consulting him in preference to daily or weekly soothsayers. At the best, however, advising the expectant mother is a somewhat delicate process. The interest she is bound to take in herself has to be guided without undue foreboding and without undue heartiness. She has to be assured that pregnancy is a natural condition and to realise that it is at the same time a period of strain. Prof. Browne achieves a nice balance. His advice is brief and practical. He deals in short paragraphs with the signs of pregnancy, its common disorders and their treatment, with preparations for confinement and with the breast-feeding and care of the baby. The chapter on the disorders of pregnancy is particularly useful, as it clearly distinguishes the normal from the abnormal and indicates when the doctor should be called in. This is important from the point of view of welfare of the patient, as when a woman has formed the habit of putting up with a lot it is quite possible for her to put up with too much. Dr. Browne is perhaps a little gloomy about constipation, which bulks large on the modern horizon in ordinary life and in pregnancy overhangs the whole sky. In all other respects this is an excellent little book.

THE DANGER OF POLISHED FLOORS

The question of suitable flooring material for the wards of hospitals recently exercised the minds of an important hospital congress,[2] and was left largely in the air. In the meantime polished wood blocks continue to claim their victims. A week or two ago Mr. E. W. Norris, coroner for Huddersfield, held an inquest upon a man of 75, a patient in St. Luke's Hospital, who had a fall in the ward and fractured a wrist when he got out of bed in the temporary absence of the nurse. Death was due to myocarditis, brought on by chronic bronchitis, accelerated by the injury to the wrist, and the coroner said he could never understand why floors in hospitals where there were old and infirm patients should be highly polished. He understood that the patients at the hospital were given slippers with leather soles, but these were a poor protection against slipping on a polished surface. Surely, he added, if the floors were well scrubbed the same clean appearance would be obtained as by polishing.

THE HOSPITAL AND THE "DOGS"

In the *Harrap Mercury* for June, issued gratis by George Harrap and Co., Ltd., the well-known publishers, is the following paragraph:

"The crying need for an up-to-date English-French dictionary was forcibly brought home to me recently. In a very well-known dictionary, widely used in schools, I found under the French word *hôpital* the following English equivalents: 'hospital, almshouse, *dogs*.' Dogs? I racked my brain—and the astonishing solution suddenly dawned on me. The English equivalent of the French expression *aller à l'hôpital* is 'to go to the dogs': the compiler of the dictionary had arrived at the momentous conclusion '*hôpital*=dogs' by the simple process of cancellation!"

We should add that Spiers in his dictionary stated that "to go to the dogs" is "*prendre le chemin de l'hôpital*," and Larousse states that "*réduire à l'hôpital*" means "*ruiner*."

Small-pox—Then and Now.—Dr. R. L. Wason writes: "In the ancient church of St. Pancras, Exeter, is a tablet to the memory of a Cornish girl who died in the year 1711 'of the smallpoxe, a distemper so remarkably fatall to her family that no fewer than foure of her sisters perished of it during the months of February and March 1716 in the burroughs of Penryn and Fowy in the County of Cornwall aforesaid.'"

ADDRESSES AND ORIGINAL ARTICLES

FUNCTIONAL EFFICIENCY AND BODY-BUILD IN THE YOUNG MALE ADULT

By H. A. Treadgold, M.D., M.R.C.P. Lond.
GROUP CAPTAIN, ROYAL AIR FORCE

Functional efficiency.—This term is used in the present paper to imply the possession of the three following attributes: (1) capacity to endure severe or prolonged physical stress; (2) capacity to endure severe or prolonged mental stress; (3) a high resistance to disease and a more rapid recovery-rate than normal if any such disease is contracted.

Body-build.—This term is used to express the relationship between age, height, and weight, and is recorded in terms of weight. Under-weight and over-weight are shown in kilogrammes below and above normal standards respectively. This normal weight for any given age and height can be obtained from various tables, principally American.

The "seven offices" tables,[1] compiled from 28,697 British males examined for life insurance in this country during 1921 and 1922, are used as a standard in the present paper. They cover ages from 15 to 60 and heights from 5 ft. 3 in. (160 cm.) to 6 ft. 2 in. (188 cm.). To avoid the inconvenience of having to refer to the tables on every occasion, F. H. Sherriff[2] suggested a formula for weight in pounds and height in inches, as follows:—

$$\text{Weight in pounds} = 2/3_x + 4(h_x - 61) + 100$$

where x = age, and h_x = height in inches at age x

and stated that in extreme cases—i.e., where the age was over 50 or the height over 72 in.—the error rarely exceeded 2 per cent., and for average ages not more than 1 per cent.

As the age-limits involved in the cases to be considered vary between 18 and 40, Mr. Sherriff has kindly provided me with two further formulæ, which, owing to the smaller range of age involved, are still more accurate.

To calculate weight in kilogrammes:—

$\text{Weight} = 2/5_x + 2/3h_x - 60$, where h_x = height in cm. at age x.

For pounds and inches, formula is:—

$$\text{Weight} = 1/11(10_x + 43h_x) - 145.$$

Even for extremes of height the error rarely exceeds 1 per cent., whichever formula is used.

The body-build of all cases shown in this paper has been obtained from the tables themselves, as the formulæ are necessarily not so accurate, but for approximate calculation of body-build they are both useful and convenient. Stripped weights and actual heights were obtained in all cases.

In order to study the connexion, if any, between variations in body-build and functional efficiency, it is first necessary to determine the average body-build of entrants to the Royal Air Force at the time of entry. Airman recruits and pilots must be considered separately as the former are examined at the R.A.F. Recruiting Depôt and considered only as to their fitness for general service, whereas pilots are examined at the Central Medical Establishment and undergo a much more searching examination. It should be explained that the term "airman" in the R.A.F. is used to designate "other ranks" as distinguished from officers. It does not, per se, imply flying capacity, but certain specially selected airmen are trained as pilots and are examined at the Central Medical Establishment in the same way as other pilots, prior to acceptance. "Pilots" include these, but consist mainly of officers.

Fig. 1 shows the body-build on entry of 1000 accepted airman recruits. These figures were obtained from the first 200 accepted during each of the five years 1928–32. The black column shows the percentage whose actual weight agreed, to the nearest kilogramme, with the normal weight for their age and height shown in the "seven offices" tables ("correct" weight). The shaded portion on each side of the black column shows the percentage falling within limits arbitrarily selected as representing a reasonable allowance for normality, and extends from −3 to +3 kilogrammes—i.e., a total range of 7 kg., equivalent to somewhat over 1 st. ("normal" cases). To the left of the shaded portion the height of the various columns shows the percentage of recruits with increasing degrees of under-weight on entry, as one reads from right to left ("under-weight" cases). The columns on the right of the shaded portion similarly show percentages in the case of over-weight recruits ("over-weight" cases). It will be seen that there are more than twice as many cases to the left of the shaded portion (31 per cent.) (under-weight cases) as there are to the right (15 per cent.) (over-weight cases).

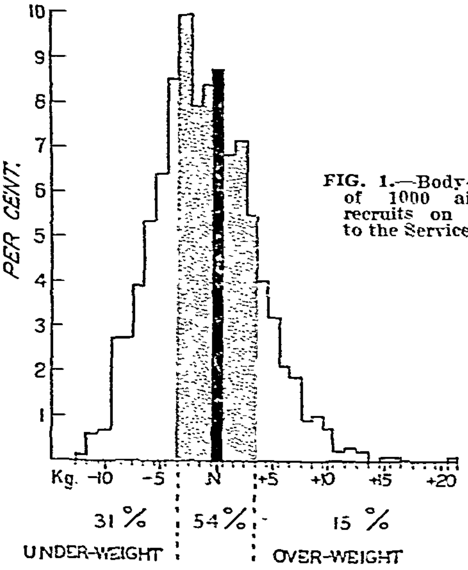

FIG. 1.—Body-build of 1000 airman recruits on entry to the Service.

This and the succeeding diagrams show the percentage distribution in one kilogramme weight-groups. The height of the black column gives the percentage of those whose actual weight agreed with that calculated from their age and height. The breadth of the column represents one kilogramme. The black column and shaded portion extending from −3 kg. to +3 kg. represent the amount allowed for normality. To the right and left of this the height of the columns shows the varying percentage distribution of over-weight and under-weight groups respectively. Average age of recruits on entry was 19 years.

Fig. 2 shows a similar series of 1000 consecutive cases of successful candidates for piloting examined at the Central Medical Establishment. Compared with Fig. 1, the main difference is that now there is a greater proportion of over-weight cases (29 per cent., compared with 15 per cent. among airmen), and a smaller proportion of under-weight cases (22 per cent., compared with 31 per cent. in airmen). The percentage of those of normal body-build as represented by the shaded and black portions of both figures is 54 for airmen and 49 for flying candidates.

[1] Tyler, V. W.: Jour. of Inst. of Actuaries, 1923, liv., 216.

[2] Ibid., 1933, lxiv., 106.

These differences are probably due to two main causes :—

(1) Candidates for flying come mainly from a higher social class than airmen, and have the advantages of a more ample and varied dietary and better hygienic surroundings in childhood and adolescence, as well as the opportunity of indulging to a greater extent in games and athletics.

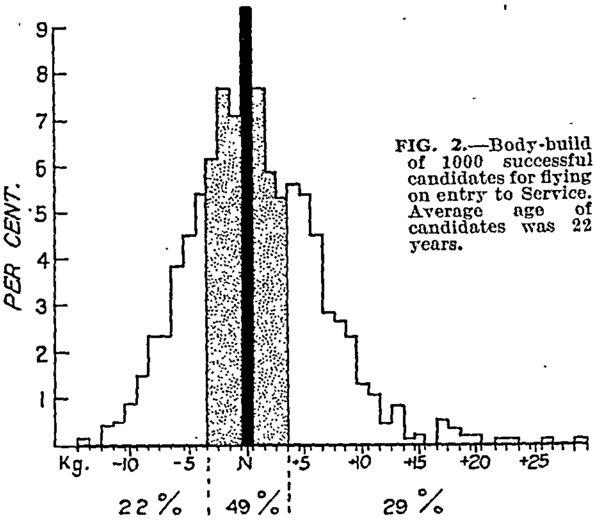

FIG. 2.—Body-build of 1000 successful candidates for flying on entry to Service. Average age of candidates was 22 years.

(2) The higher standard of fitness required in a prospective pilot results in the rejection of many who would be passed fit for " general service " alone.

As an illustration of this, all available cases rejected for flying on grounds of cardiovascular inefficiency (220), as judged by the R.A.F. tests and standards, were collected, and Fig. 3 shows that the proportion of over-weight to under-weight cases in this group compared with successful candidates shows a striking change, as the under-weight group has increased from 22 to 43 per cent., and the over-weight group has decreased from 29 per cent. in successful candidates to 14 per cent. among those rejected. Many of these cases were well up to the recruiting standard for airmen and none of them had any organic disability.

In order to investigate what relation, if any, existed between body-build and capacity to endure severe or prolonged physical stress, the body-builds of as many airmen as possible, who competed in the R.A.F. athletic championships at Uxbridge in 1933, were obtained at the commencement of training. Fig. 4 shows the body-build of these men and the marked preponderance of over-weight to under-weight cases —i.e., 4 to 1, in striking contrast to the 1 to 2 proportion in the case of recruits (Fig. 1). As a control to these figures, the body-build of 500 airmen was obtained from 25 R.A.F. stations at home in 1933 (Fig. 5). Their only qualification for admission to the series was that none of them had competed in the championships—in other words, they were a fairly typical example of the ordinary serving airman. Fig. 5 shows that although the proportion of over-weights among this control-group is higher than among recruits on entry, it is still far below the corresponding proportion in athletes in Fig. 4.

A further analysis of this series, divided up according to the different events in which they competed, is shown in Fig. 4, *a*, *b*, *c*, *d*. In the tug-of-war teams (Fig. 4 *a*) there is, as might be expected, an overwhelming preponderance of over-weights to under-weights (22 : 1). In the field events (Fig. 4 *b*) this is not so marked (6 : 1), but still very definite. In the sprints (100 yards, 220 yards, quarter-mile, 120 yards hurdles) (Fig. 4 *c*) it is reduced to 4½ : 1. In the long-distance events, however (Fig. 4 *d*), for the first time there is a definite preponderance of under-weights, who are 2½ times as numerous as over-weights.

The personnel of the recent Mount Everest Climbing Expedition, who were examined at the Central Medical Establishment before they left for India, shows an even more pronounced under-weight tendency. Of the 15 individuals examined, only 1 was over-weight (+16 kg.); his general physical condition was poor and he proved a failure. Of the remaining 14, half were definitely under-weight (more than −3 kg.) and the remainder normal (within ±3 kg. of their calculated weight from age and height).

Where sheer bodily strength is an essential factor, as in the tug-of-war and, to a less extent, in the field events, over-weights might reasonably be expected to preponderate. The marked difference in body-build between sprint and long-distance athletes, however, requires some explanation. In sprint work there is a maximum and prodigal expenditure of energy regardless of consequences for a brief period. A big frame with a well-developed and powerful musculature is best adapted to meet this, as the extra weight involved is not a serious handicap where the effort is maximal for a brief period. Long-distance work, on the other hand, involves far less expenditure of energy over the same period and its conservation is all-important. Extra body-weight must inevitably increase the work thrown on the heart, and the longer the distance the more important does this factor become. Consequently, the individual with the minimum body-weight consistent with adequate performance is likely to prove most successful in the long run. The average height and weight of the entrants of the long-distance events were 173 cm. and 63 kg., compared with 175 cm. and 68 kg. of the sprint entrants.

The conclusion to be drawn is that capacity to endure severe or prolonged physical stress, as illustrated by proficiency in athletics, is met with more frequently in over-weight than in under-weight individuals, but there is a definite exception to this general rule in the case of long-distance athletes, in whom the converse occurs. The Mount Everest personnel is a good illustration of this point.

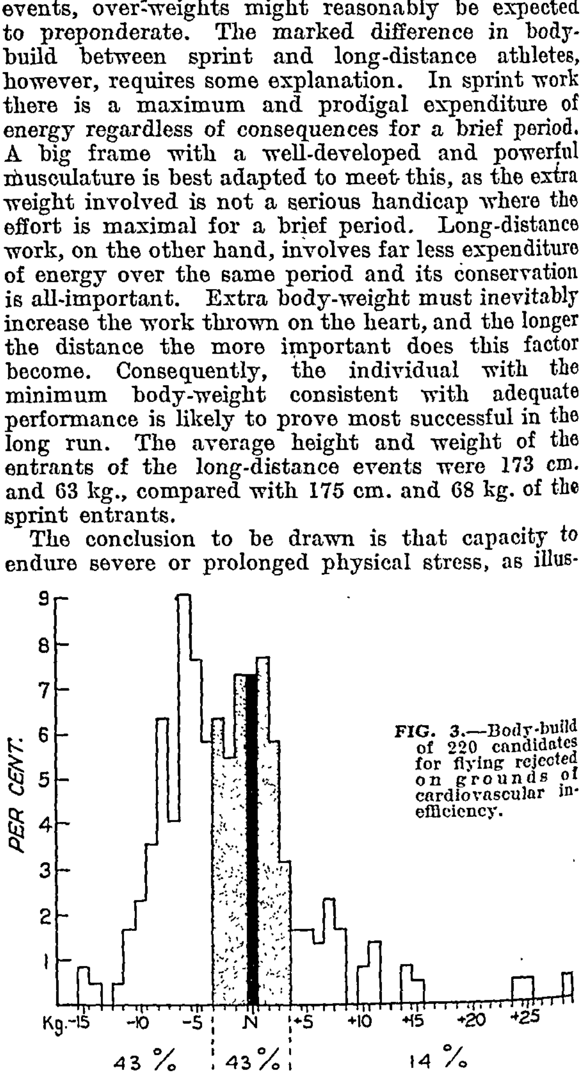

FIG. 3.—Body-build of 220 candidates for flying rejected on grounds of cardiovascular inefficiency.

The connexion between liability to disease and body-build was investigated by studying the body-build on entry of as many cases as possible among both airmen (ground personnel) and pilots, invalided from the service on purely medical grounds, no surgical cases being included. If it is granted that these cases represent, as a class, individuals whose powers of disease-resistance and recovery are below the normal of their class, a comparison between the body-build of the invalids on entry and of the normal airman or pilot will then show what part, if any, body-build plays in this connexion. Airmen and pilots must be considered separately owing to the different medical standards of entry, the different nature of their duties, and also their different treatment when the question of invaliding arises.

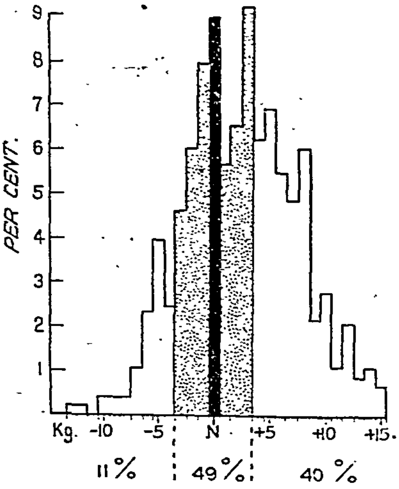

FIG. 4.—Body-build of 482 airmen in R.A.F. Athletic Championships in 1933. Average service five years.

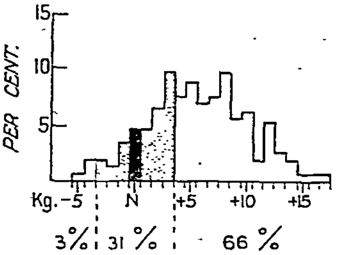

FIG. 4 a.—Body-build of 157 airmen competing in tug-of-war teams.

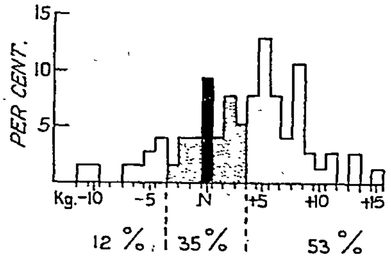

FIG. 4c.—Body-build of 77 airmen competing in sprint events.

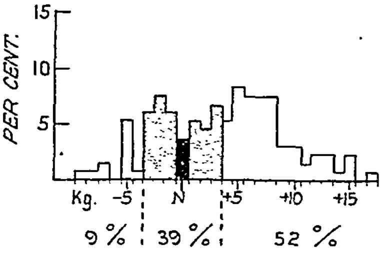

FIG. 4b.—Body-build of 134 airmen competing in field events.

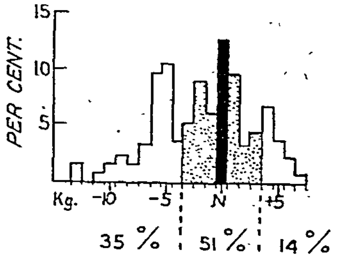

FIG. 4d.—Body-build of 130 airmen competing in long distance events.

AIRMEN

Fig. 6 shows the body-build on entry of 340 cases of airmen invalided from the Service on purely medical grounds. Comparison with Fig. 1 showing the body-build of airmen on entry reveals that the proportion of under-weight to over-weight individuals has altered from 2 : 1 to 6 : 1, the actual figures being 48 per cent. under-weight compared with 8 per cent. over-weight. Put in another way, practically half of all airman medical invalids are more than −3 kg. under-weight on entry to the Service. Fig. 7, based on the 340 cases of airman invalids, shows the relative likelihood of an airman being invalided according to his body-build on entry. Where the thick lines intersect in the middle of the diagram, the probability is represented as unity. Below this point it is less than one, above it greater than one, the ratio being indicated by the figures on the left and right of the diagram starting at 0·4 below and reaching to 4 above. To the right and left of the middle line the body-build is expressed in kilogrammes above or below normal for age and height. It will be noticed that the curve is above normal for all under-weight groups and becomes steeper as the degree of under-weight increases. The curve is below normal in cases of moderate over-weight. The diagram shows two main points :—

(1) The greater the degree of under-weight on entry the higher is the probability of invaliding.

(2) The minimum probable invaliding-rate occurs among those who are +3 kg. to +6 kg. on entry.

This is interesting as bearing out the experience gained in the examination of pilots at the Central Medical Establishment, that a high degree of functional efficiency, as shown by the examination as a whole, is usually associated with a moderate degree of over-weight on entry.

In order to investigate the question whether different classes of disease were associated with different degrees of body-build on entry, all cases were divided up into infective diseases (148 cases), non-infective diseases (90), and psychic disorders (102).

The commonest form of infective disease was pulmonary tuberculosis (37), in which only 1 case was over-weight (+5 kg.) on entry. The most frequent diseases among the remainder were other chronic lung conditions exclusive of asthma (14), chronic otitis media (30), and rheumatic carditis (19). Fig. 8 shows that the ratio of under-weight to over-weight cases on entry among this class is 8 to 1.

The commonest causes of invaliding in the non-infective group were epilepsy (24), defects of vision (18), organic nervous disease (13), and gastric conditions (9). Fig. 9 shows that the proportion of under- to over-weights on entry was less than in Fig. 8—i.e., 5 to 1—but still more than twice as much as the normal proportion on entry (Fig. 1).

The remaining group of psychic disorders includes the psychoses and psychoneuroses (Fig. 10). This group is taken as illustrating the type of airman who would probably be incapable of withstanding severe or prolonged mental stress in that this type has already broken down under the minor stresses of peace-time. Here, too, the under-weight class shows a preponderance of 4½ to 1, less than in the other two groups but sufficient to suggest that the under-weight recruits as a class have less capacity to withstand mental stress than those whose body-build is above normal.

PILOTS

Invaliding figures from medical causes among pilots, almost entirely officers, comprise 147 cases. Fig. 2 showed that there was a preponderance of over-weight to under-weight cases on entry of roughly 5 to 4. Fig. 11 shows that among the invalids this ratio was practically 1 to 3. Comparison with the similar figures for airmen (Figs. 1 and 6) shows that the swing to the left is approximately the same among both pilot and airman invalids when their marked difference of body-build on entry is taken into account.

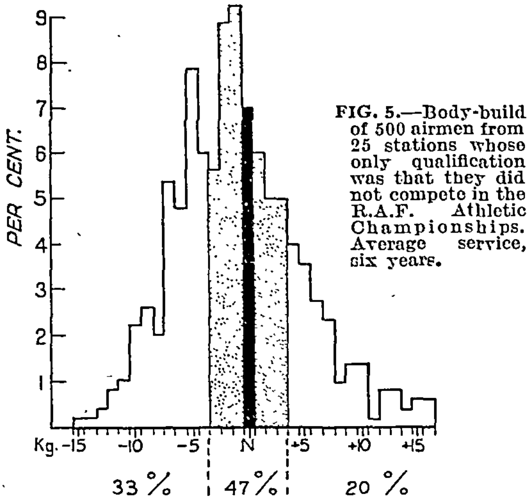

FIG. 5.—Body-build of 500 airmen from 25 stations whose only qualification was that they did not compete in the R.A.F. Athletic Championships. Average service, six years.

Analysis of the figures under the three heads of infective, non-infective, and psychic causes shows a marked difference from the airman group.

(1) The infective group is the smallest (32 cases), representing 22 per cent. of the whole compared with 44 per cent. among airmen. This marked difference is probably due to two main factors: (*a*) the more careful selection of pilots on entry, and (*b*) the fact that the conditions of officers' service are more comfortable, and they are treated with more leniency than airmen as regards sick leave if there are reasonable prospects of ultimate return to full duty and allowed a prolonged period of home service under such conditions.

(2) The non-infective group is a larger one (48 cases), equal to 33 per cent. of the whole, compared to 26 per cent. among airman invalids. Here again no comparison can be made, because more than half the cases among pilots were due to disabilities affecting only their efficiency as pilots, such as defective oculo-motor balance (31 per cent.) and air-sickness (20 per cent.). Neither of these is a cause of invaliding among airmen.

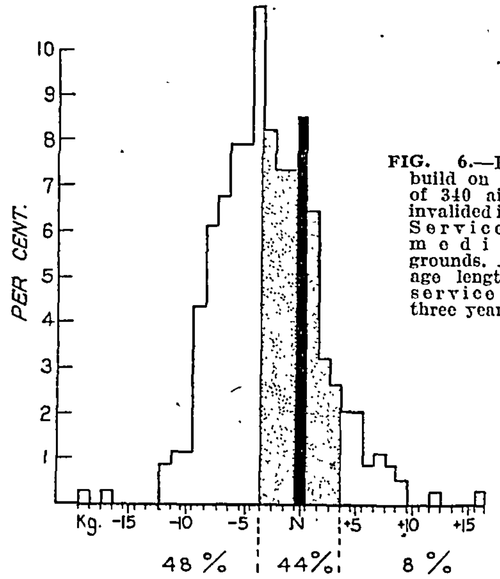

FIG. 6.—Body-build on entry of 340 airmen invalided in the Service on medical grounds. Average length of service was three years.

(3) Psychic disorders represent the largest class (67 cases), 45 per cent., compared with 30 per cent. among airmen. Here again the two are not analogous, as a third of the cases among pilots consisted of anxiety neurosis due to flying, a class not represented among airmen. A young pilot has to be fit for full flying duties, and if he develops an anxiety neurosis to a degree that medical opinion considers a permanent bar to active service flying, he is usually invalided, although many of such cases are quite fit for general service apart from flying. The psychoses represent a third of the total invalidings among airmen, but among pilots only 2 per cent. were invalided from this cause. This difference is probably due to the more searching examination of pilots on entry.

The question next arises to what extent individuals of one body-build group are liable to increase or decrease in weight beyond the normal amount that occurs with age. Reference to Fig. 1 (body-build of airmen on entry) and Fig. 5 (body-build of representative airmen in the Service) shows that the under-weight group has remained very much the same at 31 and 33 per cent. respectively, but that there is a slightly larger increase in the over-weight group, the original 15 rising to 20 per cent. A corresponding sample of 500 serving pilots also shows the largest increase in the over-weight group. Thus the percentage of under-weight pilots on entry was 22 per cent. (Fig. 2), and while serving 23 per cent. The percentage of over-weights, however, increased from 29 per cent. on entry to 38 per cent., twice as

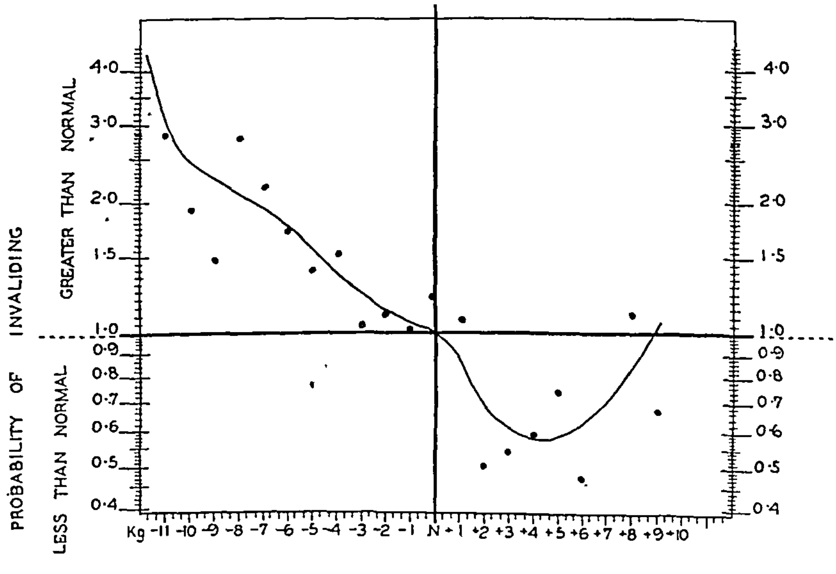

FIG. 7.—Showing ratio of probability of invaliding in airmen according to their body-build on entry to that in airmen of "correct" body-build.

much, in fact, as in the airmen. Finally, if the body-build of the R.A.F. athletes (Fig. 4) is compared with their own body-build on entry, we find that the percentage of over-weights has practically doubled (from 22 to 40 per cent.) and the percentage of under-weight cases has, unlike the other two groups in which it has remained much the same, undergone the marked diminution from 29 to 11 per cent.

This increasing tendency towards over-weight as one goes from the control-airman group to the pilot group, and finally to the athlete group, is probably due to the different amounts of physical exercise and training, both of which are well-known factors in weight production, in the three groups.

Alteration in the under-weight group is, in fact, almost confined to the athletes, among whom these factors would naturally play the major part. The liability of athletes to put on weight after training or, as the saying is, "turn their muscle into fat," is probably due to the continuance of the excellent appetite acquired as a result of continued exercise, when there is no longer any need for it. The natural result is the deposition of fat generally over the muscles.

It must not be assumed, however, that apart from athletes individuals under-weight on entry remain so or that the increasing percentage of over-weights during service is entirely at the expense of the normal body-build group. This is not so; there is a definite degree of interchange among all three groups, but it is rare to find members of the under-weight group becoming over-weight or vice versa.

The most stable of the three is the over-weight group. Among athletes, 86 per cent. of cases over-weight on entry remained so after five years' service; in the control-airman group, 80 per cent. after six years' service. None of the athlete over-weights became under-weight and only 5 per cent. of the airmen. The least stable of the three groups is the under-weight. Thus of the athletes under-weight on entry only 30 per cent. remained so, the balance becoming normal (62 per cent.) and over-weight (8 per cent.). Among the airman group, 48 per cent. remained under-weight and 8 per cent. changed to the over-weight group.

Approximately half of all airmen invalided from medical causes were −4 kg. or lighter on entry to the Service. This figure rises to 70 per cent. if all cases are taken whose body-build was −1 kg. or lighter (Fig. 6). It would appear on the face of it that the bulk of medical invaliding could be avoided by admitting into the Service only those recruits whose weight was "correct" or greater. In the first place, however, the material is not available, and in the second place it has been shown already that there is a definite percentage of under-weight individuals who are functionally efficient

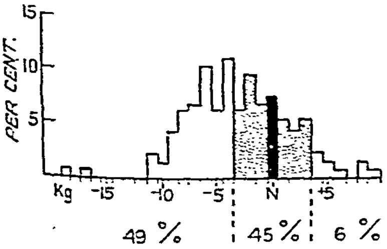

FIG. 8.—Body-build on entry of 148 airmen invalided on account of infective disease.

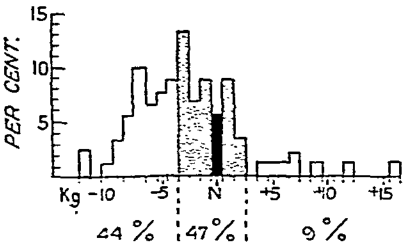

FIG. 9.—Body-build on entry of 90 airmen invalided on account of non-infective disease.

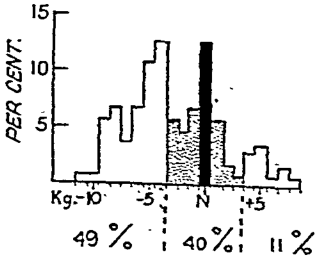

FIG. 10.—Body-build on entry of 102 airmen invalided on account of psychic disorders.

to a high degree. Consequently, the essential point is the differentiation at the time of entry of the under-weight who is functionally efficient and likely to remain so, from the under-weight who, even if passably fit on entry, is unlikely to stay so. This is a comparatively easy matter if attention is paid to the following points.

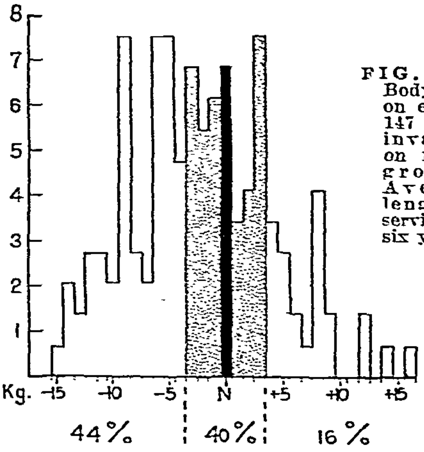

FIG. 11.—Body-build on entry of 147 officers invalided on medical grounds. Average length of service was six years.

It should be borne in mind that the typical under-weight is usually of poor physique, is not as a rule efficient in athletics, and tends to have a small heart and consequently tachycardia, and a narrow, poorly developed chest with a subnormal vital capacity. In addition, his family and personal history tends to reveal evidence of poor mental stamina, and his previous illnesses are usually more frequent and their duration longer than normal.

If, however, on examination a candidate, although under-weight, has a good games history, a pulse below 72—the lower the better, as indicating the possession of a heart whose output per beat is above average—a good vital capacity, and a clean family and personal medical history, little risk will be incurred in accepting him. Difficulty occurs in the under-weight cases between these two types, and the physical efficiency tests employed in the R.A.F. are particularly valuable in final assessment.

Under-weights, apart from the tuberculosis risk which occurs mainly below the age of 30, are viewed as a whole with greater favour than over-weight individuals by life insurance offices owing to their better expectation of life. This is probably due to the relatively sheltered lives they lead owing to their tendency to poor functional efficiency and also to their proneness as a class to arterial hypotension and consequent relative immunity to most of the cardiovascular catastrophes of later life. From the point of view of sickness insurance, however, the under-weight compared with the over-weight individual appears to be more undesirable owing to increased liability to disease.

CONCLUSIONS

(i) There is a definite relationship between varying degrees of body-build and functional efficiency, whether viewed from the points of capacity to endure severe or prolonged physical or mental stress or resistance to disease generally.

(ii) Capacity to endure severe or prolonged physical stress as evidenced by athletic prowess is found most commonly among over-weights. An exception to this is seen in long-distance athletes among whom under-weight is commoner than over-weight.

(iii) Incapacity to endure severe or prolonged mental stress, as evidenced by invaliding from the Service through psychic disorders, is commoner among individuals under-weight on entry to the Service than among over-weights.

(iv) This applies also to disease as a whole, and particularly in the case of infective diseases, such as pulmonary tuberculosis. The greater the degree of under-weight on entry, the greater the likelihood of invaliding from the Service on medical grounds.

(v) It is uncommon for over-weight individuals to become under-weight and vice versa.

(vi) As a general rule it is not difficult to distinguish between the "fit" and "unfit" types of under-weight by careful examination.

My cordial thanks are due to those of my brother medical officers of the Royal Air Force who have furnished many of the figures relating to airmen, and to Miss I. M. Marshall for her valuable assistance in the preparation of diagrams and figures.

INCIDENCE OF
HUMAN AND BOVINE BACILLI IN TUBERCULOUS MENINGITIS

BY A. STANLEY GRIFFITH, M.D. Vict., Ph.D. Camb.
MEMBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL

IN a paper published in 1932[1] I summarised the results of typing strains of tubercle bacilli obtained from 140 cases of tuberculous meningitis occurring in this country, which had been investigated during the years 1905 to 1931 by L. Cobbett, A. Eastwood, F. Griffith and myself.

The strains of tubercle bacilli were derived in 77 instances from post-mortem material and in 63 from cerebro-spinal fluid withdrawn during the life of the patient. In the first or necropsy series, which were mostly examined before 1914 and were to some extent selected, since search had been made for cases in which the portal of entry appeared to be the alimentary tract, the percentage of bovine infections was 19·5 (62 human and 15 bovine), while in the second or cerebro-spinal fluid series, collected mainly after the year 1920, the percentage bovine was 30·2 (44 human and 19 bovine). Thirty of the latter group were examined by me between March, 1930, and July, 1931, and of these 10 were bovine infections. Thus, it is seen that the percentage of bovine cases in the most recent series, in which there was no element of selection, was 33·3 or more than half as high again as in the first series, although as I have already mentioned the latter were specially selected on account of their supposed alimentary origin. The cases in the two series were not, however, obtained from the same part of the country, those in the first having been derived mainly from hospitals in London, whereas those in the second came from other and widely separated localities, including country districts, in England. For this reason one could not decide whether the higher bovine percentage in the recent series signified an increase of late years in the relative frequency of bovine infections in tuberculous meningitis, or was referable merely to the different provenance of the cases.

In order to clear up these points it was necessary to undertake further investigations. The inquiry was therefore continued with the object of ascertaining the relative incidence of the human and bovine types in tuberculous meningitis in various parts of England and Scotland.

Nature and Source of Material

The material used in the investigation was principally cerebro-spinal fluid withdrawn by lumbar puncture during the life of the patient. In a few cases of tuberculous meningitis material from autopsies was investigated in addition to spinal fluid, and in eight cases post-mortem material only was used.

The use of cerebro-spinal fluid as original material, as I have previously pointed out (loc. cit.), has a special value from the statistical point of view. In the first place a far greater number of cases of tuberculous meningitis occurring in a locality can be examined than if one depended on material from autopsies, which moreover would not give a fair sample. In the second place the typing of strains of tubercle bacilli from cerebro-spinal fluid gives some indication of the extent to which at present the general population is being infected with bovine bacilli, since tuberculous meningitis occurs mainly in young children and in them supervenes comparatively closely on infection.

Determination of the types of tubercle bacilli in tuberculous meningitis would be of great value to health authorities in yet another way, as K. A. Jensen[2] has also suggested. If periodical investigations of all cases occurring in selected areas over certain periods were made, the data so obtained would enable one to estimate the effectiveness of measures taken to reduce the incidence of tuberculosis in cattle, particularly if the cases came mainly from rural and urban districts where milk is not heat-treated before sale for direct consumption.

During the period from December, 1931, to December, 1933, material was received from 204 cases. Of these 188 yielded cultures of tubercle bacilli, while the remainder (15 spinal fluids and one autopsy) were negative, neither direct cultures nor tuberculosis in guinea-pigs being produced. The cultures were all obtained in my laboratory with the exception of those (see Table I.) which were kindly sent to me by Drs. F. Griffith and W. M. Scott (Ministry of Health), and Dr. W. T. Munro (Glenlomond Sanatorium). In each of 16 cases the material received was an uncut inguinal gland of a guinea-pig which had been inoculated subcutaneously with spinal fluid; for these I am indebted to Drs. Constant Ponder and J. Menton, bacteriologists to the Kent and Stafford county councils respectively.

The cases of tuberculous meningitis were derived from the following places in England and Scotland: Kent, Bristol, Gloucester, Wolverhampton, Stafford, Sheffield, Manchester, Liverpool, Leeds and the West Riding, Hull, Newcastle-upon-Tyne, Ayr, Dundee, and Aberdeen. To the medical officers of health of the cities, towns, and county councils, and to various physicians and bacteriologists who have aided me in this inquiry, I wish to express my grateful thanks.

Methods of Examination and Results

Each specimen of cerebro-spinal fluid was injected subcutaneously into one or two guinea-pigs, and at least one strain of tubercle bacilli from each case was obtained either through the guinea-pig or directly from the original material. The guinea-pigs were killed in from 18 to 42 days and cultures were invariably made from the glands adjacent to the seat of inoculation. Where two guinea-pigs had been inoculated the second was held in reserve in case the first attempt at culture failed or, when necessary, for confirmation of the first result. In 38 out of 58 cases cultures were also obtained directly from the cerebro-spinal fluid, the undiluted fluid or centrifuged deposits being sown after treatment with potassium hydrate (2·5 per cent. in the mixture) or sulphuric acid (3 per cent.). The number of colonies obtained in direct cultures varied from one to numerous. In two cases cultures were obtained both from the cerebro-spinal fluid and from post-mortem material, and in eight cases from post-mortem material only.

The total number of strains from the 188 cases was 237, of which 222 were derived from cerebro-spinal fluid (38 direct and 184 through the guinea-pig) and 15 from post-mortem material. In every instance where two or more strains from a single case were examined these proved to be identical in cultural characters and, where this was tested, identical also in virulence.

The primary cultures were made both on plain egg and on 5 per cent. glycerin egg. The characters of the colonies of tubercle bacilli on these two media enable one, as I first pointed out in 1914,[3] to decide in almost every case, and generally within four weeks, to which type (human or bovine) a strain of tubercle bacilli belongs. (The avian bacillus can also be distinguished in primary cultures but has never been found in human tuberculous lesions in Great Britain.) All the strains in this series were either human or bovine. As the cultural differences between human and bovine tubercle bacilli are well known it is unnecessary to give a detailed description of the cultural characters of the various strains obtained, and I shall merely state how many were human and how many bovine. With regard however to those strains of human type, which were not tested as to their virulence, I may mention that no strain was classified as "eugonic human" unless it produced abundant wrinkled growths on glycerinated potato, which in my experience is the most reliable medium for differentiating eugonic human from dysgonic human and bovine strains.

Of the 188 cases of meningitis 140 yielded eugonic human strains. Five only of these strains were tested as to their virulence, one rabbit being inoculated subcutaneously with each, the doses ranging from 20 to 50 mg. The five rabbits were killed 90 to 182 days after inoculation and in two the lesions were limited to the seats of inoculation, while in three there were in addition to local abscesses a few small lesions in the lungs and in one a slightly enlarged purulent scapular gland.

The remaining 48 cases yielded cultures with the cultural characters of the bovine type of tubercle bacillus. All these strains were tested as to their virulence for the rabbit by the subcutaneous or the intravenous inoculation of culture. The test suspensions of culture for subcutaneous inoculation were prepared by a simpler method than in previous investigations.

Instead of subculturing a strain for several generations and giving weighed amounts of culture I took either primary egg cultures from three to four weeks old, or first subcultures on egg four to six days old, the latter being made by spreading over the surface of each tube a drop of an emulsion of a primary culture. It was found that an average tube thus sown and incubated for from 5 to 6 days yields when scraped about 1·0 mg. of culture. The suspensions for inoculation were prepared directly in the culture tubes by rubbing off the growths with a spatulated platinum wire and suspending them in physiological salt solution; young cultures of bovine bacilli readily form homogeneous suspensions. From one to five tubes were used, the larger number only when the primary cultures showed not very numerous colonies. The doses therefore varied but never exceeded 10·0 mg. which was the standard dose in previous investigations, and ranged usually from about 1·0 to 5·0 mg. As will be seen, although the doses were generally much less than 10·0 mg., the duration of life of the rabbits and the severity of the disease produced showed much the same range of variation as in previous series where the dose was always 10·0 mg.

Altogether 50 dysgonic strains from 48 cases of tuberculous meningitis were tested on rabbits, six of them intravenously* and the rest subcutaneously. All the strains proved highly virulent for the rabbit, producing severe general tuberculosis identical with that which follows similar inoculation of bovine tubercle bacilli of direct bovine origin. With three strains the tests had to be repeated because the rabbits, inoculated subcutaneously, died in 19, 20, and 23 days, and the tuberculosis though generalised was insufficient to account for death. The subsequent tests showed these strains to be fully virulent.

Excluding the three rabbits dying prematurely and two others which survived 101 and 105 days there are 47 subcutaneously inoculated rabbits which died of general tuberculosis in from 28 to 95 days, the average duration of life being 52·3 days. The rabbits which died in 101 and 105 days had been given small doses—namely, one primary culture each; the tuberculosis produced however was severe and typical. The six rabbits injected intravenously died of general miliary tuberculosis in from 23 to 53 days.

Another dysgonic strain obtained in the course of this investigation, from a woman of 27 who had had no illness previous to the meningitis, has had to be omitted because its type has not yet been definitely ascertained. This strain was tested subcutaneously on a rabbit, the growth from one primary culture being inoculated. The rabbit was killed 108 days later, having nearly doubled its weight, and was found to have a local lesion and a few foci in the lungs only. The virulence test was repeated and two rabbits were inoculated intravenously, doses 0·01 and 0·1 mg. These were killed 71 and 49 days later and found to have slight general tuberculosis. These experiments showed that the strain though resembling dysgonic bovine bacilli in cultural characters had no greater virulence for the rabbit than human tubercle bacilli. In order to decide whether the strain was an attenuated bovine strain or a very unusual dysgonic form of the human group of bacilli further tests of virulence were necessary. These have been made on rabbits and guinea-pigs but are not yet completed.

Sources of Infection

Inquiries were made into the milk-supply in the majority of the bovine cases of meningitis with the object of tracing the source of the bovine bacilli. Such inquiries could be expected to be fruitful only in cases where the interval between tuberculous infection and the occurrence of tuberculous meningitis was comparatively short, as it often is in quite young children. Where tuberculous meningitis due to bovine bacilli supervenes in the course of chronic tuberculosis it is too late to investigate the milk-supply. In a few instances the inquiries led to the discovery of cows giving tuberculous milk and to their slaughter earlier than otherwise would have been the case, but they mostly had negative results, the veterinary inspectors failing to find, or to obtain a history of a clinical case of tuberculosis in the herds supplying the milk.

---

* By Dr. W. T. Munro.

The following are examples of the results of the inquiries. At one farm the cows were inspected and appeared healthy but a group sample of the milk, taken immediately after the inspection, was shown by the guinea-pig test to contain tubercle bacilli. The farm was visited again and after a more thorough examination of the cows one suspicious animal was picked out. A sample of her milk was taken and was found to contain tubercle bacilli. The cow was then slaughtered and showed extensive tuberculosis.

Of the inquiries which were inconclusive as regards the source of infection the following may be quoted.

Two children, 15 months and 2 years of age respectively, from different households in the same street and receiving milk from the same producer-retailer, died within about six months of each other of tuberculous meningitis due to bovine bacilli. A bulk sample of this man's milk was tested and gave a negative result. Sufficient time however had elapsed before the taking of the sample for a doubtful cow to have been removed from the herd. In this instance I asked the medical officer of health (Kent) if other cases had occurred which could be attributed to this retailer's milk and he informed me that there was one child suffering from abdominal tuberculosis. In another instance a boy of 3 years died of tuberculous meningitis due to bovine bacilli and an infant of 11 months (not investigated) who had been supplied with milk from the same source was suffering from tuberculous peritonitis. The conditions on this farm (in Kent) were most unsatisfactory, though none of the cows appeared to be giving tuberculous milk. The farmer of course had been notified that his herd was to be inspected and had had ample time to dispose of any animal which he did not wish the veterinary surgeon to see.

In one case, a child of 6 years, infected with bovine bacilli, the autopsy (performed by Dr. S. C. Dyke, Wolverhampton) showed no lesions in the mesenteric or the tracheo-bronchial glands. The lungs, however, were extensively tuberculous and cultures of bovine bacilli were obtained from them as well as from the spleen and the meninges. The father of the child was said to have pulmonary tuberculosis, but a specimen of his sputum could not be obtained. With regard to the portal of entry of the bacilli in this case, it is uncertain whether the infection was through milk or transmitted from the father.

In all other cases with a family history of tuberculosis the bacilli causing the meningitis were found to be of the human type. Two of these cases were sister and brother, aged 2½ and 4½ years, and they died within two months of each other. Their mother suffered from pulmonary tuberculosis and was discharging tubercle bacilli in her sputum.

Distribution of Lesions found at Autopsy

The post-mortem notes of 33 of the cases investigated have been sent to me and are summarised as follows. The tubercle bacilli responsible were of the human type in 21 and of the bovine type in 12 cases.

Of the 21 cases due to human tubercle bacilli 15 showed older and more extensive tuberculous changes in the tracheo-bronchial than in the other regionary lymphatic glands, indicating infection by way of the respiratory tract, while of the remaining six the channel of infection was uncertain in four and probably alimentary in two.

In eight of the first group of 15 cases the lungs contained in each instance, besides miliary tubercles, a caseous nodule or mass, which was considered to represent the primary lesion, and in seven no primary lung focus was found. Of the six cases in the second group, in two the regional lymphatic glands were not examined and in two both the thoracic and abdominal regionary lymphatic glands contained lesions. In a fifth case, one of general miliary tuberculosis, careful search by Dr. A. D. Fraser (Bristol Royal Infirmary) failed to reveal any disease in the tracheo-bronchial or abdominal glands, or any primary focus in the lungs. Instances of acute general miliary tuberculosis without macroscopic lesions to mark the portals of entry of the bacilli have been recorded occasionally. A. Eastwood and F. Griffith [4] reported a case of tuberculous meningitis (due to bovine bacilli) without macroscopic primary focus, and J. C. Hendrie [5] has recently reported two cases. The sixth case was remarkable for the occurrence of extremely numerous large tubercles on the parietal and visceral surfaces of both peritoneum and pleura. No tubercles were seen in the substance either of the lungs, spleen, or kidneys. The mesenteric glands were enlarged and congested, though not caseous, and the late Dr. Egerton Williams (Sheffield) thought that the infection was probably of alimentary origin.

Of the 12 bovine cases eight were straightforward instances of alimentary tuberculosis, the channel of infection being the intestinal canal. Six of the eight cases were in children 22 months, and 2, 4, 4, 4, and 6 years of age and two were in adolescents, one female and one male, both 18 years of age. In the children the mesenteric or the ileocæcal glands were extensively caseous. No intestinal ulcers were found, but the Peyer's patches in the upper ileum of one child were hyperplasic. In two of the cases there were miliary tubercles in the lungs, liver, and spleen, while in four miliary tubercles were not seen in the abdominal or the thoracic organs; in three cases the peritoneum showed miliary tubercles, in one case profuse. In none of these six cases were lesions reported in the tracheo-bronchial glands.

In the young woman the mesenteric glands were completely calcified and the lungs were closely beset with miliary caseous tubercles. At the base of the brain there were two or three small caseous nodules in addition to miliary tubercles. The youth had suffered from tuberculosis of the cervical glands in 1930, and in 1933 was treated for enlarged glands in the groin; the axillary glands were also enlarged. In December, 1933, he was notified as a case of tuberculous meningitis. At the autopsy (by Dr. M. Scott, R.M.O., Heathfield Hospital, Ayr) the lungs were found to be very adherent on both sides and extensively infiltrated with tuberculosis of a broncho-pneumonic type without cavitation or evidence of older disease. Both kidneys showed much fibrocaseous infiltration with nodules of walnut size. There was definite tuberculous meningitis with a gelatinous exudate over the base of the brain. The mesenteric glands were extensively implicated and showed partial caseation.

In the remaining four bovine cases the distribution of the lesions was unusual.

In one case, a girl of 9 years, there was general miliary tuberculosis, the lungs being closely and the kidneys sparsely beset with macroscopic tubercles, while in the liver and spleen the foci were microscopic. No lesions were found in the regional lymphatic glands, but debris suggesting diseased bone was extracted from the upper nasal area and Dr. T. B. Davie thought that this might have been the primary seat of the disease, the meninges becoming involved through the cribriform plate.

In the second case, previously mentioned, there was general tuberculosis of the lungs but no disease of the tracheo-bronchial or mesenteric glands.

In the third case, a boy of 2½ years, Dr. A. D. Fraser found caseous tuberculous glands at the hilum of the right lung, typical tuberculous meningitis, and no sign of tuberculosis elsewhere. Dr. Middleton Martin caused inquiries to be made into the family history and the milk-supply of this case. No history of tuberculosis in the parents or attendants could be elicited, but it was ascertained that the child had been supplied with milk from a tuberculous cow.

In the fourth case, a girl of 9 years, the left prætracheo-bronchial glands contained calcified and caseous material and one intertracheo-bronchial a well-encapsulated calcareous focus. There were no lesions elsewhere except on the meninges.

Thus in two "bovine" cases the oldest tuberculous lesions were seated in the tracheo-bronchial glands, and apart from tuberculosis of the central nervous system no lesions were noted in any other part of the body. Cases of this kind, where the tuberculous infection is bovine and apparently primary in the thorax, have been reported from time to time but they are rare. The first case was recorded by me in 1920.[6] Munro[7] reported three cases in 1932. Blacklock[8] described three cases, occurring among 183 autopsies, in children aged 9 months, 18 months, and 2¼ years. In these the tracheo-bronchial glands (two cases) or a paratracheal (one case) were extensively caseous but no primary pulmonary lesions were found. The three children died of general miliary tuberculosis and tuberculous meningitis.

In view of the fact that phthisis pulmonalis due to bovine bacilli is by no means rare in this country (in the last ten years or so Cumming, Munro, and Griffith have found upwards of 80 instances), it is possible that these children or some of them may have been infected with bovine bacilli from human sources.

Tuberculomata of the central nervous system were recorded in two cases only.

In one autopsy there were two cerebellar nodules, one of which was presenting on the surface. In the other there were soft caseous nodules on the meninges. In three instances it was stated that no tuberculomata were found on section of the brain. In the remainder typical meningitis only was described. It is probable that the majority of the brains were examined merely to establish the presence of tubercles on the meninges and thorough search was not made for older tuberculous foci in some part of the central nervous system or its bony surroundings. The absence of record of associated tuberculomata is not necessarily opposed to the conclusion of Rich and McCordock,[9] who believe that tuberculous meningitis can only be produced by direct extension from a pre-existing lesion in the cortex of the brain, the meninges, or the bones of the skull or the vertebræ. My experiments on animals and observations in the human subject support this view of the pathogenesis of tuberculous meningitis.

In seven of the present series of cases there were no miliary tubercles anywhere except on the meninges, the primary seats of the disease in three instances being the mesenteric glands and in four the tracheo-bronchial glands, which were enlarged and caseating. As there were no miliary tubercles elsewhere in these cases the tubercles on the meninges could not have been produced by blood-borne bacilli and must, I think, have been the result of extension of the tuberculous infection from an undiscovered focus in close relationship to the meninges.

Another case for which I think the same explanation holds good was in a boy of 4½ years, who died of tuberculous meningitis and showed at autopsy a few miliary tubercles in the liver and spleen and a single caseous slightly calcareous mesenteric gland. Dr. Nabarro sent me the gland and on microscopical examination I found numerous short acid-fast bacilli which suggested bovine infection. An emulsion of the gland however did not produce tuberculosis in guinea-pigs and direct cultures remained sterile; the bacilli were dead. In this case therefore the meningitis could not have been the result of a sudden discharge into the general circulation of large numbers of bacilli from the caseous gland.

Regional Distribution of Bovine Cases

Table I. gives the different localities contributing material, the number of cases from each locality, and the proportion of human and bovine infections in each group. With the exception of Newcastle-upon-Tyne and two counties which sent 1 and 3 cases only every locality has yielded one or more bovine cases. The absence of a bovine case in the Newcastle series is probably attributable to the small number of specimens submitted for examination and to the predominance of persons in the higher age categories (8 of the 13 were over 8 years of age); moreover all but one of the patients were resident in the city. The evidence of widespread infection of human beings with bovine bacilli in England and Scotland furnished by this inquiry is corroborated by recent bacteriological investigations of other forms of human tuberculosis—namely, cervical gland, bone and joint, and genito-urinary tuberculosis, in which high bovine percentages have been found. Reports of these investigations are in preparation.

* Including the 30 reported in 1932.

As will be seen from Table I. the proportional frequencies of bovine infections in tuberculous meningitis are in general higher in Scotland than in England.

The cases from Fifeshire and Dundee were examined by Dr. W. T. Munro, to whom I am much indebted for cultures of the bovine strains and for allowing me to include the results he has obtained down to October, 1933. The Aberdeen cases included three in persons who were not residents of the city. One, a youth of 15, was a native of the Orkney Islands; the type of bacillus in his case was the bovine. One of the patients came from the Shetland Islands and one from Elgin; these were both human infections. The remaining 12 cases were residents of Aberdeen and of these six were due to human and six to bovine bacilli. The four Ayrshire cases were in persons ranging in age from 16 to 22 years.

The total number of Scottish cases examined is 37, of which 15, or 40·5 per cent., were caused by bovine bacilli. In England 214 cases (151 recent and 63† from earlier series) have now been examined and of these 52, or 24·3 per cent., were bovine infections. Tuberculous meningitis in Scotland thus falls into line with all the other forms of human tuberculosis in showing a higher bovine percentage than the respective forms of the disease in England.

---

† Only 30 of these included in Table I.

While in Scotland the bovine percentages for the different localities were high and showed little variation, in England they have varied widely, from 0·0 per cent. in Newcastle-upon-Tyne to 60·0 per cent. in Staffordshire. The figures for the cities and towns must not however be taken to represent the actual proportional incidence of bovine infections on the inhabitants of these places. On ascertaining the home addresses of the patients it was found that many were not residents, having been sent into the city hospitals from neighbouring small towns or villages, or from the outskirts of the cities, and that these rural or suburban cases were due in higher proportion to bovine bacilli than were the city cases.

The bovine case from Hull was in a child of 6 years, who until a few weeks before death had lived in a village in the East Riding of Yorkshire where his father worked on a farm.

One of the Sheffield bovine cases came from the neighbouring town of Chesterfield. The Liverpool and Manchester cases were from the suburban districts of these cities. Of the Manchester cases one, a child of two, had been fed on raw milk. The milk of the producer-retailer who supplied the household had been tested three months previous to the death of the child and found to contain tubercle bacilli. The second case from Manchester was a girl of 18 years. The tuberculosis in this case was of some standing, the mesenteric glands showing calcified lesions. The Bristol case was from a village in Gloucestershire and is one of the two referred to under autopsies in which the oldest and only glandular lesions were in the thorax. The London case was in a child aged 22 months, who had been sent in for treatment from a small town in Essex.

The 66 Leeds cases (1930 to 1933), for which I am greatly indebted to Dr. Wilfred Vining (professor of children's diseases, University of Leeds) and to his various house physicians, are subdivided in Table I. into city and country cases, the latter coming from small towns and villages in the West Riding of Yorkshire. Of the 49 residents 39 were infected with human and 10 with bovine bacilli. Of the 17 cases in non-residents nine were due to human and eight to bovine bacilli. In one of the latter cases, the source of the bovine bacilli could not be traced in the West Riding and it was thought that the child was infected on a visit to Wallsend, near Newcastle-upon-Tyne. Assuming this to have been so the percentage of bovine infections for the country districts of the West Riding is 43·75.

The cases from the country districts of Kent have also yielded a high proportion of bovine infections. Through the courtesy and kind coöperation of Dr. A. Greenwood and Dr. Constant Ponder I have been able to examine 35 cases of tuberculous meningitis from Kent. Of these, two were in persons who were not residents of the county. Omitting these two there are left 33 cases of which nine, or 27·3 per cent., were due to bovine bacilli. Twenty-four of the persons were under 16 and of these eight, or 33·3 per cent., were bovine infections. At one stage of the inquiry (in 1932) the percentage of bovine infections in Kent children was 50, but a sequence of cases due to human tubercle bacilli towards the end of 1933 has reduced it to 33·3.

From the country and small urban districts of North Staffordshire five cases have been examined and here also the proportion of bovine infections was high. Of the five cases three were due to bovine and two to human bacilli. The persons infected with bovine bacilli were two children aged 19 months and 2 years and a woman of 22. The woman lived on a farm where there were tuberculous cows and the first of the two children had been supplied with milk from a source from which a positive sample had been taken four months previously.

Age and Sex Frequency

For the purposes of this section the 63 cases previously reported are included. There are thus 251 cases available for statistical analysis.

Sex.—The sexes of the patients were given in 247 cases. Of this number 131 were males and 116 were females. The males were preponderant in the first five years of life and in adult age. In the age-period 5–14 years the females equalled the males. In adolescence the females exceeded the males. Of the males 38 (29·0 per cent.) and of the females 28 (24·1 per cent.) were infected with bovine bacilli.

Age.—In Table II. the cases have been analysed to show the relative frequency of human and bovine infections in each of the first seven years of life and at age-periods 0 to 4, 5 to 14, 15 to 24, 25 and over, and at all ages. The ages of two cases in an earlier series were not recorded. These cases, infected with human bacilli, are included in the all ages group only.

Total ..	251*	184*	67

* Including two cases age not stated.

In the first year of life the percentage of bovine infections is comparatively low—namely, 15·0—probably because unheated cow's milk is not usually given to babies. After one year the percentage bovine rises sharply to 40·0 in the second and 45·8 in the third year. In these years cow's milk is frequently consumed in the raw state. In the fourth year the percentage falls to 23·1, or about half what it was in the third year, and in the fifth and sixth years rises slightly. The high percentage figure in the seventh year may be fortuitous, as it is based on a small number of cases. In late childhood (7–14) the percentage incidence falls to 14·3 and rises again during the period of adolescence. The adolescent figure 26·3 is nearly as high as that—namely, 27·3—for the ages 3 to 5.

The infection in two of the adolescent cases was evidently acquired several years before the fatal issue and it is probable that a high proportion of the older children and adolescents were infected in early childhood.

Summary

1. The results are given of typing the strains of tubercle bacilli obtained from a new series of 188 cases of tuberculous meningitis collected during the period from December, 1931, to December, 1933.

2. Of this number 48 (25·5 per cent.) were due to bovine bacilli and 140 (74·5 per cent.) to human bacilli.

3. The cases were derived from widely separated localities in England and Scotland. The number of English cases was 151, of which 33 (21·8 per cent.) were bovine infections. The number of Scottish cases was 37; of these, 15 (40·5 per cent.) were due to bovine bacilli.

4. Including the 63 cases previously reported the total number of English cases investigated is now 214. Of these, 52 (24·3 per cent.) were caused by bovine bacilli and 162 by human bacilli.

5. The percentages of bovine infections at different age-periods (English and Scottish figures combined) are as follows: 0 to 4 years: *31·3*; 5 to 14 years: *23·3*; 15 to 24 years: *26·3*; and 25 years and over: *10·0*.

6. The bovine cases were widely distributed and varied greatly in proportional frequency in different localities, country places and small towns, in general, giving higher percentages than the cities.

PELLAGRA IN SUDANESE MILLET-EATERS

By N. L. Corkill, M.B. Liverp.
SUDAN MEDICAL SERVICE

In May, 1933, I encountered symptoms unfamiliar to me in a desert community of Arabs at Abu Deleig in the Butana Desert of the northern Anglo-Egyptian Sudan. It was apparent that these people were suffering from a considerable degree of avitaminosis. In June 103 members of the tribe were examined, their medical histories were recorded, and their individual diets were assessed.

It became obvious that the community was pellagrous and it appeared that most of its members were in a state of disease, proclaimed by certain physical signs, suggesting that the pellagrous process has a phase preceding subjective manifestations, a phase of activity in which such manifestations dominate the picture, and a post-active phase in which a measure of more or less toleration to the process has been evolved. The staple diet was found to be millet. W. H. Wilson (1921) has recorded pellagra in millet-eaters in Egypt and two cases have been recorded from the Sudan in an annual report of the Sudan Medical Service (1929). In the past it has been usual to ascribe the "absence" of pellagra from the Sudan as due to the millet diet of its inhabitants as compared with the maize diet of most Egyptians.

I use the term pellagra in reference to the symptom-complex which is commonly found associated with the dermatitis which has itself occasioned the more classical conception of pellagra as a predominantly skin affection. In this I follow the guidance of Manson-Bahr (1925). Last November, through the kindness of Dr. D. Riding, of the Public Health Department, Cairo, I was introduced to Dr. H. W. Dudgeon and Emeritus Prof. W. H. Wilson, who very kindly demonstrated a series of male and female pellagrin inmates of the asylums at Abbasia and Khanka near Cairo. The same fundamental process was found in the pale maize-eating Egyptians as in the darker millet-eating Sudanese, but in the former the skin symptoms were severer and no blue or black patches on their gums or tongues were to be found.

For the purposes of my inquiry the 103 individuals were divided into four clinical groups: those with severe active pellagra (all women), those with less severe active pellagra (all men), those with what I considered to be latent pellagra (all men), and those whose condition would not have suggested pellagra if divorced from the circumstances (all boys). A fairly strict purdah tradition prevented my seeing any young girls. The groups of men were then pooled and re-analysed into three new groups according to whether they drank milk daily, less than daily in the average week, or not at all in the average week. The percentage incidence of active pellagra was then estimated for each of these milk consumption groups. Lastly, data relating to cases of mental disorder in males and females of the affected tribe were collected.

The present paper gives a summary of the findings and an outline of the views based on them. A more complete account of the observations will be published later.

FINDINGS

Certain physical signs were common to most adults of the community but were more pronounced and more frequently found in multiple association in those with subjective symptoms and considered to be suffering from active pellagra.

These signs were "sulphur-flake" sebaceous dysfunction on the forehead, wings of the nose, cheeks, and chin; a stomatitis characterised by the pronounced impression, as if in wax, of the lateral aspects of the closed rows of teeth on the mucous membranes of the cheeks (hereafter called the buccal frieze*); glossitis of various forms (fissures, rawness, blueness, blue, black, or dark red patchiness, and in very many a stippling at the tongue margins in blue, black, or dark red); blueness or blackness of the gums in patches or to complete involvement; and in certain subjects a deepening of the natural pigmentation on the forehead and cheeks.

The commonest subjective symptom was a burning pain in the hands, feet, head, and interscapular region. This pain came at night or on going into the shade after being in the sun. It came daily in the hot dry season "when the sun went down." In the rainy season it disappeared. Some subjects got it at seasons other than the hot dry season if they "worked hard," "rode a camel," or "got tired." It was often associated with "swelling of the skin" followed by desquamation. Other common symptoms were a gnawing or "hot" pain in the epigastrium (as characteristically present as the burning pain in the extremities, both generally being present together), weakness, wasting, flatulence (very common), vomiting, diarrhœa (often bloody), joint pains, lumbago, formication, vertigo, sleep dysfunction, and mental disorder.

Certain cases of asthma, paroxysmal rhinorrhœa and dietetic intolerance, and such histories as that of a pellagrin who said that always after a shower of rain for about half an hour "the skin of all his body felt swollen," suggested an allergic factor.†

---

* I have noted a similar appearance in a much lesser degree in Europeans, Hamites, Semites, and Negroids, in all of whom pellagra could not be said to be obviously present. Is it a sign of vitamin-A deficiency?

[illegible] l out a series of skin tests on pellagrins [illegible] of them the condition of factitious [illegible] asioned, and further, that they were [illegible] on and whole-millet. These investi- [illegible] elsewhere.

Variable knee-jerks and spinal tenderness suggested the clinical entity of subacute combined degeneration. The mental cases comprised maniacs and melancholiacs, mostly the latter. In a high proportion of them there was amelioration in the rainy season and recurrence or exacerbation in the hot dry season. *Among 13 female cases 7 (of whom 5 were brides)* committed suicide. Among 14 male cases 1 had committed suicide and 3 had attempted to do so. The more severe the pellagra the less was the incidence of dental caries. It is therefore of interest to note that the teeth of the modern Egyptians are proverbially good; it has been claimed that most of them are pellagrins.

Of interest, but less commonly noted, were: deprivation or abstinence symptoms relating to coffee and millet, tenderness of the calves without œdema or cardiac dysfunction, tongue tremor, stammering, night-blindness, ptosis, and various urinary affections of an undetermined nature. Eye affections existed but no diagnostic attention was paid to them owing to lack of time.

Statistically and clinically, women were found to be more severely affected. The disease occurred in the first decade, was most common in the third decade in both sexes, and became in a proportion of male cases later in life more or less quiescent or inactive. Occupation was a factor inasmuch as it governs insolation and accessibility of the milk-supply. Insolation daily was estimated for each person examined and, although exposure to the sun was associated with dermatitis and the burning pain which came on in the shade or darkness after exposure, yet the group with severest pellagra—the women—averaged only 1·7 hours exposure daily as compared with 6·7 and 7·0 in the male groups, the less severely pellagrous The first group, incidentally, may be presumed to have photosynthesised vitamin D to a much lesser degree than the two male groups. Certain pellagrous manifestations appear to have been activated from latency by katabolic acceleration in the form of "fatigue"—i.e., exercise or labour, malaria, and viperine poisoning.

The hot dry season was the period of maximum occurrence, recurrence, and exacerbation of symptoms.

There were found to be, also, significant curves on a graph on which were plotted the quarterly figures for deaths and conceptions (antedated births). There was a peak of deaths in the rainy season which immediately follows the hot dry season, the period of maximum pellagra activation. This is interpreted as showing that a pellagrous community after its seasonal affliction is especially susceptible to the infective diseases associated with the rainy season, the period of maximum microbic and insect activity. A very marked depression in the conception curve was present in the hot dry season, and as it cannot have been due to vitamin-E lack, for the amount of millet consumed if anything increases in this season, it must be ascribable either to vitamin-A lack or to the essential pellagrous process.

As extremes of cold and humidity, as well as sudden changes of temperature and humidity, also occasioned pellagrous manifestations (cf. activation of allergic phenomena in common experience) I consider that the seasonal factor may be included in a wider conception, which is atmospheric crisis, by which is meant extremes or rapid changes of temperature and humidity.

The food of paramount importance to this community for both quantity and quality—i.e., vitamin value—is milk. In its comparative absence in the hot dry season it appears that the cereal toxamins of Mellanby (1932) have optimum conditions for exerting their effects. It was found that in the most severely pellagrous group coffee consumption was highest, and it is therefore of interest to note that intolerance to coffee has been recorded by Lickint—i.e., coffee is a potential allergen. The consumption of meat and green vegetables amongst these natives was almost negligible. Many of them in the hot dry season eat nothing but whole-millet. The variety is *Sorghum caudatum*, Stapf, *var. feterita*, a miserable white or cream grain of recognised poor food value. A neighbouring Arab tribe, the Shukria, who eat mainly a bigger grain of a yellow to orange colour, *Sorghum durra*, Stapf, are known to be less severely pellagrous.

W. H. Wilson (1921), utilising a table published by Thomas (1909), has shown that, in pellagrous diets, the biological protein value (B.P.V.) is below the critical value of 40 to 45 g. per diem. The daily averages for all groups in Abu Deleig were below this figure. Certain histories suggested that millet, coffee, and milk might serve as allergens in pellagrins. Samples of the local well waters were taken for analysis and found to be high in calcium content.

DISCUSSION

Impressive findings were that there was an allergic factor involved deriving from the food, that pre-active, active, and post-active phases of the disease existed; that in the hot dry season, the period of maximum active pellagra and intensest insolation, the population was practically deprived of its vitamins A, the postulated B_2 and C, and also of its food source of vitamin D and cholesterol; and, lastly, that in this season also the B.P.V. of a diet fell below the critical value of 40 to 45 g. daily—*meaning that* some persons were living on their own cell-protein, and that others on the borderline might have to do so in the event of increased katabolism demanding extra nitrogen utilisation. In the circumstances it has seemed not unreasonable to add yet another to the numerous theories of pellagra, none of which has explained all the phenomena associated with the disease.

No place has been found, in my theory, for water-soluble vitamin B_2. Its existence has been postulated on laboratory findings in monkeys and rats and on the therapeutic effects of diets in pellagrins. It has not been isolated and no evidence as to its chemical nature has been put forward. Further, the existence or otherwise of phytosterol, cholesterol, and ergosterol in B_2-free diets used for laboratory experiment is not always clear. One or more of these three substances *is to be found in all diets on which pellagrins* have improved; milk, meat, liver, green vegetables, and yeast are ready examples.

The fundamental condition in pellagra is, in my opinion, one of multiple avitaminosis and cholesterol-lack. The vitamins primarily concerned are the fat-soluble A and D; a lack of C is contributory. The action of cereal toxamins is thus permitted to add the signs and symptoms of their effects to those *associated with deficiency of the vitamins.*

Lack of vitamin A may be held to account for impairment of the integrity of epithelial surfaces, thus conducing to the entry to the blood stream of potential allergens: foreign protein substances, from the mouth, stomach, and intestine. Deficiency of vitamin C as it impairs capillary walls may also be considered to facilitate allergic manifestations. Lack of cholesterol, phytosterol, and ergosterol in the food, concomitantly with *vitamin D, means that if this* latter is to be obtained by the tissues, cholesterol must either be synthesised in the body or mobilised from the body's store; this exists most notably in the brain, spinal cord, gonads and adrenals.

Vaughan, quoted by Clark (1932), has claimed that whenever protein is broken down there is liberated a protein poison, which is soluble in alcohol, diffuses through membrane, and on injection into a dog produces anaphylactic phenomena. The B.P.V. of pellagrous diets implies that cell-protein is broken down, and thus Vaughan's soluble protein poison is presumably available as a potential allergen in pellagrins.

If, now, the medley of signs and symptoms embraced by the term pellagra be considered, it will be seen that most of them can be ascribed to one or other of the factors detailed above. To lack of vitamin A may be ascribed stomatitis, possibly glossitis, gastritis (dyspepsia), enteritis, bladder affections, vulvo-vaginitis, the preputial affection described by Stannus (1911–12), night-blindness, sterility and, indirectly through toxamin effects, subacute combined degeneration. Further, it contributes to the causation of allergy. (It is of interest that allergy exerts its effects impressively on skin and mucous membrane, the epithelial tissues and those on which vitamin-A deficiency works havoc.) Vitamin-C deficiency appears to be responsible for the discoloration of the gums and possibly also of the tongue. It may also be to blame for tenderness of the calves and certain joint affections.

To lack of vitamin D and consequent mobilisation of the body-cholesterol may be ascribed headache, vertigo, formication, irritability, epilepsy, mania, melancholia, sleep dysfunction, sexual dysfunction, pigmentation abnormalities and subacute combined degeneration. (The exact relationship between toxamin effects and the fat-soluble vitamins is not clear.) Pathological findings in pellagra are notably present in the central nervous system, in the gonads, and in the adrenals. Writers quoted in the Medical Research Council's report for 1932 have shown that vitamin D may be prepared from highly purified crystallised cholesterol obtained from brain tissue.

To quantity-starvation—i.e., a low B.P.V.—may be primarily ascribed wasting, for the pellagrin has to use up first of all his body fat; thereafter demands on his cell-protein will account for a state of active or potential allergy. Allergic manifestations have been claimed above to depend upon atmospheric crisis; to this may now be added actinic and tactile trauma.

It is well known that the dermatitis of pellagra, while very obviously affecting the areas of the body exposed to the sun, also affects "pressure points"—i.e., places of tactile stimulus, such as the elbows and the knees. I noted with interest that the Egyptian pellagrins in Cairo were affected on the knees, elbows, buttocks, and over the trochanters: one of them who had attempted suicide some time before bore the pigmented trace of the rope and knot round his throat. That a similar or common process is at work in Addison's disease readily suggests itself. In short, in pellagra tactile stimuli, particularly if repeated, may induce manifestations of reaction.

Wright quotes the experiments of Lewis on the response of skin by a state of factitious urticaria to heat, cold (extremes and rapid variations), and touch; a causative vaso-dilatory substance of a histamine-like nature, known as H-substance, being postulated. It has been suggested that the reaction of the skin to light trauma by redness, desquamation, pigmentation, and increased reaction after six months, described by Finsen, is of a similar nature and also due to H-substance. It seems, further, that this H-substance may be the soluble protein poison of Vaughan. The dermatitis of pellagra seems to have everything in common with these phenomena.

The dermatitis of pellagra is an allergic response to light and tactile trauma and the pigmentation is protective. Allergens are known to vary in allergic power—certain pollens as compared with others, for example—and it seems reasonable to assume that response to trauma will be greater in those in whom greater allergen content is circulating in the blood. From this it seems natural to find that, as a rule, the more severely ill a pellagrin is the more severe are his skin symptoms. That pigmentation is protective is suggested by several facts.

Some Sudanese pellagrins who said that they once upon a time suffered from the characteristic burning pain of the extremities but had not done so for several years were appreciably darker than their fellows and some of them had a very definite deepening of pigmentation on the forehead and cheeks. Secondly, the women pellagrins at Abu Deleig, who are strikingly pale as compared with the males, were very much more severely ill. Thirdly, among these Sudanese cases the palms and soles and sides of the palms and soles, and not the dorsal aspects, usually showed burning and desquamating: the palms and soles of the Sudanese are much paler than are the dorsal aspects of their hands and feet. Fourthly, the Egyptian pellagrins were very much more ill than were any of my Sudanese cases and they were much paler. Further, on the sites where the dermatitis had completed its active phase and the scabs were falling away, I was astonished to see that there was no appreciable residual pigmentation in the skin beneath (the scabs were pigmented, of course). Were these Egyptians so severely ill because they could not deposit permanent protective pigment?

The rôle, if any, of photosynthesised vitamin D in pellagra has not yet been discussed. That it does play a part is suggested by the facts that the blood-calcium is increased in pellagrins and that the severer the disease the less the dental caries. In other words, there is possibly an unusual photosynthesis of this vitamin in progress. Hou, quoted by the Medical Research Council (1932), has shown that birds derive vitamin D from the sebaceous preening gland. In pellagra the sebaceous glands hypertrophy (or at any rate their orifices do) and pour forth a yellowish secretion on the surface of the skin; this secretion has been aptly likened to sulphur-flakes. Prof. Wilson, of Cairo, demonstrated to me that if a microscope slide was drawn down the nose of a pellagrin, the sulphur-flakes would powder away and no greasy smear would be left on the slide, as was the case with a slide drawn down the nose of a non-pellagrin. This, in addition to being a useful clinical aid, suggests that the sebaceous glands are an important site of vitamin-D manufactured from mobilised body cholesterol; the photosynthesised vitamin D being used up almost immediately it is made and the sulphur-flakes being the non-fatty by-products or residuum; normally sebum is rich in cholesterol and fats.

That vitamin D is an antidermatitis vitamin may be read into the fact that the burning pain of pellagra, which is presumably a phase of the dermatitis, comes on when a subject enters the darkness after being exposed to light, the suggested explanation being that when vitamin D is so lacking through its absence from the food, as also are cholesterol, phytosterol, and ergosterol, what little can be produced from body sources is probably immediately utilised in countering sun-trauma. The effects of this, however, are more lasting, and thus come into conscious appreciation in the dark when sunlight is no longer available to continue the frantic manufacture of minute but effective quantities of vitamin D.

It would be only natural that a vitamin manufactured in the skin should have a special relationship to the health of the skin, and I suggest that vitamin D is the antidermatitis and possibly also an anti-allergic vitamin. There are no data suggesting its mode of action except that the blood-calcium is raised in hypervitaminosis D (as in pellagra) and thus may conduce to the control of allergic phenomena.

It seems that pellagra on diets other than cereal diets, in cases of gastro-intestinal disease and in the alcoholic (who has a lessened appetite and an impaired gastric mucosa), may be explained by the fact that the entrance of allergens to the blood from the alimentary canal and from cell-protein broken down to maintain the nitrogen balance, is to be expected. Given a degree of vitamin-lack, particularly vitamin-D lack—and here the question of adequate insolation in prisons, asylums, and poverty is of interest—there is then wanting only atmospheric crisis and sun trauma for pellagrous manifestations to develop. In England, cases occur in the bright sunshine of spring after the dull, sunless winter, a period of vitamin deprivation. In the Sudan the fierce insolation, the vitamin deficiency, and quantity-starvation all occur together.

The importance of maize in the history of pellagra seems to be explainable by two things. First, maize, after oats, has the highest toxamin value among cereals and therefore will require a bigger amount of the fat-soluble vitamins to keep its evil effects in abeyance than will millet and wheat. Secondly, maize is the staple diet of vast populations living in subtropical and tropical areas where a hot, dry season results in vitamin deprivation, semi-starvation, and actinic trauma for a period of four to five months a year. The rôle of maize is thus incidental, while at the same time the Italian insistence on its containing a toxic factor is vindicated.

In conclusion, certain points of anthropological interest emerge. One is that, as women are more severely affected than men, a pellagrous tribe that is endogamous tends to extinction, preceded possibly by polyandry, or to become exogamous. Another point is that the vulvo-vaginitis and preputial dermatitis of uncircumcised pellagrins (cf. the cases of Stannus in Nyasaland) are possibly greater factors *in the origin, spread, and popularity* of male and female circumcision than are the magico-religious mechanisms usually advanced in explanation. As usual, the fact is more important than the belief.

SUMMARY

(1) Pellagra in a Sudanese community of millet-eaters is described. From 103 individuals data were collected relating to occupation, diet, sun-exposure, medical history, and present condition.

(2) The following facts emerged: (*a*) In the period of maximum incidence of pellagra, the hot, dry season, the community's main protein, cholesterol and vitamin supply (which is its milk) sinks to a practical deprivation; millet alone remains as a food item. (*b*) An allergic factor is present in pellagra. (*c*) The severer the pellagra, the less the degree of dental caries. (*d*) Objective signs of the dermatitis of pellagra in these pigmented Sudanese are rarely appreciable.

(3) In a new theory of the causation and nature of pellagra it is suggested: (*a*) that the fundamental condition is a lack of cholesterol and vitamins A and D in the food, lack of vitamin C being a contributory factor; (*b*) that pellagra is largely allergic and that the evils resulting from cholesterol and vitamin-deficiency contribute to the syndrome, as do also cereal toxamin effects; (*c*) that pigmentation is protective against the actinic and tactile traumata affecting the skin of pellagrins; (*d*) that vitamin D, and not the hypothetical water-soluble vitamin B_2, is the anti-dermatitis vitamin.

I am indebted to Dr. E. D. Pridie, director of the Sudan Medical Service, for permission to publish this paper.

THE PRACTICAL TREATMENT OF RICKETS IN CHILDREN *

By J. R. W. Hay, M.D. Aberd., D.P.H.
ASSISTANT MEDICAL OFFICER OF HEALTH, COUNTY OF ABERDEEN; FORMER MEDICAL SUPERINTENDENT, WOODEND MUNICIPAL HOSPITAL, ABERDEEN

In the concluding paragraph of a recent report to the Medical Research Council, Spence[1] suggests that "there are sufficient cases of human rickets in the big towns living under conditions which are suitable for comparative therapeutic tests of antirachitic substances." The following observations made in 1929 are therefore submitted in the belief that they may still prove of value to investigators in this field.

The difficulty then experienced seems to be intensified to-day—namely, the assessment of the potency of the many antirachitic preparations and agencies available. It was observed that rickets cases even while in hospital were receiving more than one preparation, were exposed to sunlight, and, in addition, were placed under ultra-violet lamps. The results, albeit excellent, could not be attributed to any one agency. It was decided, therefore, to run parallel series of cases employing different "curative" agencies with controls on the lines of biological experiment.

Beds were allocated in Woodend Municipal Hospital, and rickety children were received from the child welfare clinics under the direction of the maternity and child welfare officer for the city of Aberdeen. Little difficulty was experienced in selecting suitable cases in children from two to three years of age exhibiting gross rickets. The predominant type in Aberdeen was the fair, plump, soft child, with square head and thickened epiphyses. Beading of the ribs was common but craniotabes rare. The most obvious deformity was seen in the lower limbs, all degrees from bowing to sharp angulation being observed in the cases selected. Greenstick fractures of the radius and ulna were common.

X ray appearance.—Each child was radiographed on admission, the appearances of the tibia and fibula being taken as an index of rickets. These bones were selected in preference to the radius and ulna since deformity could be noted as well as the acuity of the disease. Most of the cases belonged to Bromer's[2] second or active type. Broadening of the rarefied diaphyses was seen, and in the older children compensatory periosteal thickening of the distal end of the shaft ("beaker" type of Gottsche). The epiphyses were shadowy and ill-defined. Under successful treatment the osteoid layer thickened, producing the typical cuff (manchette), the epiphyses became distinct, and ultimately the clean-cut outline of normal bone was taken as evidence of cure.

For *classification* purposes three grades of severity of rickets were recognised.

R. 1 (mild), where the diaphyseal line was blurred and slightly broader than normal, with a corresponding lack of sharpness of the epiphyseal centre.

---

* In part communicated in a paper read to the Association of School Medical Officers of Scotland, Aberdeen, June 3rd, 1933.

R. 2 (moderate), where there was distinct broadening of the diaphysis with an indistinct or wavy outline, combined with rarefaction of the shaft and an indistinct epiphysis.

R. 3 (severe) when the diaphysis was blurred, "cupped," or appeared "frayed out" and the epiphysis not seen at all.

The degree of deformity was similarly designated.

D. 1 (mild). Showing slight uniform bowing of the shaft.

D. 2 (moderate). Marked uniform bowing.

D. 3 (severe). Showing sharp angulation or twisting.

FORMS OF TREATMENT COMPARED

The experiments were made during the winter months and all natural ultra-violet radiation was excluded from the children, who were confined to bed in a special ward. The following daily diet was strictly adhered to in all the groups: porridge with cream, toast, cocoa with milk; soup, mince and potatoes, milk pudding with cream; bread, toast or biscuits, with milk or cocoa; warm milk. Fresh fruit was allowed.

Controls.—The ten rickety children selected received the above diet only, and were excluded from all ultra-violet radiation. The general condition of the children improved greatly, but skiagrams taken at the end of four, six and eight weeks revealed little, if any, change in the appearance of the bones.

Ultra-violet irradiation.—A similar series (seven cases) were exposed to the radiation of carbon-arc lamps. The output of these lamps before and after the course of treatment was 80–140 units according to the resistance employed as measured by the photoelectric method.[5] The power at normal setting of the control resistance was 90 units, which corresponds to the production of a first degree erythema in 4·2 minutes at three feet distance for unpigmented skin in an adult of average sensitivity. Graduated daily exposure with a maximum of 20 minutes at five feet was adopted. Subsequent radiograms showed that in most cases cure was effected within four weeks and in all cases at the expiry of eight (Table I.). The outlines of the bones were clean-cut and decisive.

TABLE I.—*Effects of Ultra-violet Irradiation on Severity of Rickets*

No.	Age.	Date in 1929.	Before and after treatment.				
			Class.		Date in 1929.	Class.	
			R.*	D.*		R.	D.

7	2 2/12	August 8th.	4	2	Oct. 11th.	0	1

Class. = classification.
R* 1, 2, 3 = degree of severity of rickets. D* 1, 2, 3 = degree of deformity.

Quartz-mercury vapour lamps were equally effective using similar dosage as measured by erythema or by the photoelectric cell, but carbon-arc lamps were preferred since their ultra-violet ray output remained more constant throughout the period of the experiment; also many children could be exposed simultaneously to one lamp.

Cod-liver oil was administered to five children. The oil was obtained locally. The producers gave the vitamin-D content to be 200 units of antirachitic activity per gramme as measured by the "line" test.[4] One drachm was given per day, no difficulty being experienced in getting the children either to take or tolerate it. Radiograms showed satisfactory healing within six weeks in most instances (Table II.), but the results were not so clear as those which were obtained by ultra-violet irradiation.

TABLE II.—*Cod-liver Oil*

12	2 11/12	,, 29th.	1	0	,, 10th.	0	0

Vitamin-D product I.—This was a proprietary preparation originally derived from cod-liver oil; but later, in 1929, a preparation of irradiated ergosterol was marketed under the same name. The latter product was used in the work here described. The full daily dose ♏4 as given to six children purported to be three times as active as one drachm of cod-liver oil. The results, given in Table III., were frankly disappointing.

TABLE III.—*Vitamin-D Product I*

17	2 5/12	Jan. 15th.	3	1	March 2nd.	1	1

Vitamin-D product II was similar to vitamin-D product I, but by the addition of malt, fruit juice, &c., contained also the accessory vitamins A and C. Skiagrams showed this product to resemble closely vitamin-D product I in its efficacy.

Vitamin-D product III was an irradiated ergosterol product and was given to seven children. The full daily dose given corresponded to half an ounce of cod-liver oil as regards vitamin-D potency. The results are shown in Table IV. It will be observed that these were generally severe cases of rickets and that the ergosterol was not administered for much longer than one month since the ward was in demand and it was desirable to heal the cases quickly. Accordingly, as in the other groups the unhealed case received four weeks' course of ultra-violet ray treatment and in every instance cure was effected. The results of the irradiated ergosterol group, however, were at such variance with

those reported by other workers, such as Hess,[5] that several samples were tried out on rats by Mr. H. D. Griffith of the natural philosophy department of Aberdeen University. From his experiments he concluded that "the sample of ergosterol used was either incompletely activated or it had lost its activity subsequent to preparation." In one group the rats had actually received daily a dose equivalent to a daily dose of 13 tablets to a babe, with no demonstrable effect.

Cost of treatment.—If the vitamin-D products had proved efficacious, the cost of treatment would have been as follows : Cod-liver oil, 4*d.*, vitamin-D products I and II, 8*d.* each, and vitamin-D product III, 1*s.* 8*d.*, for the full course.

After results.—In June, 1933, the cases treated in this series were reviewed, and of 27 children 4 could not be traced and one had died of pneumonia. The remaining 22 showed permanently healed rickets with fully corrected deformities as regards the lower limbs. Four of these were said to have been exceptionally healthy since discharged from hospital. Four others had not enjoyed good health, the disabilities reported being acute mastoiditis, corneal ulceration, and general debility.

CONCLUSIONS

(1) When once developed rickets requires more than an adequate diet to ensure an expeditious cure. (2) In ultra-violet therapy we have a rapid curative agency, the artificial variety (e.g., carbon-arc lamp) being especially suitable for clinics and institutions. (3) A reputable brand of cod-liver oil is probably the cheapest effective substance and one which lends itself to domiciliary administration in the cure or prevention of rickets. (4) Regarding the many expensive preparations of the "potted alphabet" type, which doubtless to-day contain their quota of antirachitic units, it is suggested that a preliminary trial *in children* such as has been described, should be made before employing them on a larger scale. (5) I may add that although deformities may ameliorate under treatment, surgical intervention is advisable for the grosser forms and should not long be delayed.

Grateful acknowledgment is made to Dr. J. A. Stephen, maternity and child welfare officer, Aberdeen, for his invaluable coöperation throughout, to Mr. H. D. Griffith, Aberdeen University, who conducted the animal experiments and assessed the U.V.R. output of the lamps, and to Dr. H. J. Dawson, school medical officer, Aberdeen, who collected the cases for review.

CLINICAL AND LABORATORY NOTES

TWO CASES OF MENINGITIS DUE TO BACILLI OF PFEIFFER TYPE

BY S. C. DYKE, D.M. Oxon., F.R.C.P. Lond.
CONSULTING PATHOLOGIST TO THE ROYAL HOSPITAL, WOLVERHAMPTON; AND

C. J. HARWOOD LITTLE, O.B.E., M.B. Leeds
PATHOLOGIST TO THE ROYAL WEST SUSSEX HOSPITAL

MENINGITIS due to organisms of the Pfeiffer type is by no means common in this country. Hence it has been thought worth while to place on record two cases in both of which recovery ensued.

DR. DYKE'S CASE

The patient was a male aged 22. A radical mastoid operation was performed in 1928; since then the health had been good. On May 6th, 1933, while at a football match he became conscious of a profuse watery discharge from the left ear; he mopped it up from time to time with his handkerchief but otherwise paid no attention to it. Next day the discharge had ceased; he had a slight headache but otherwise felt well. On May 8th the headache was worse but he was able to go to Birmingham on business in the morning; at 11 o'clock he became very dizzy, vomited, and started to feel very ill. He was able to return to his home 15 miles away; on the following day he was seen by Dr. C. A. Day. The temperature was 101° F., the pulse-rate 70; he complained of violent headache and pain in the neck and over the sternum, and he vomited several times during the day. On May 10th the pain in the head and neck was a great deal worse; temperature 102°, pulse-rate only 68; he was seen by an aural surgeon (Mr. W. Hallchurch) who could find nothing in the ears to account for the trouble.

On the following day he was removed to a nursing-home where he was seen by myself in consultation with Dr. Day. Temperature at this time 101°, pulse 62. The pain in the head and neck was very violent; the patient showed Kernig's and Brudzinski signs, otherwise physical examination was negative. Lumbar puncture was performed, and turbid fluid obtained under pressure. Examination of the fluid showed numerous pus cells but no organisms could be seen. In view of the apparent aural source of the infection the streptococcus was regarded as the most likely cause of the infection and it was decided to inject antistreptococcal serum. A second lumbar puncture was performed and 30 c.cm. of turbid fluid withdrawn. A mixture of 10 c.cm. each of polyvalent antistreptococcal and of antiscarlatinal serum (B. W. & Co.) introduced intrathecally.

The fluid withdrawn at first puncture was sown into glucose ascitic broth and on to an ascitic agar plate, half of which had been covered with a thin layer of human blood agar as a means of identifying hæmolysis should streptococci be present. The broth gave no growth, but after 48 hours' incubation the plate showed numerous minute colonies growing only on the blood-covered half of the plate. Microscopically the organisms consisted of a very minute Gram-negative rod morphologically identical with the bacillus of Pfeiffer. Attempts to subculture it were unsuccessful and it was never again obtained from any subsequent puncture. The fact that it grew only in the presence of blood classed it as hæmophilic, and this, together with its appearance, served to identify it as a member of the Pfeiffer group.

The patient continued to run a temperature up to 102° for two weeks; for the first week the condition remained practically unchanged; lumbar puncture was performed daily on six consecutive days; on every occasion turbid fluid under pressure was withdrawn. From the end of the first week on there were signs of improvement, and lumbar puncture was performed on alternate days for three days, making a total of twelve punctures in 16 days.

In the first specimen of cerebro-spinal fluid the cells, all polymorphs, were too numerous for counting. By May 15th they had fallen to 2000 per c.mm., thereafter they fell until on the 17th they had reached about 400 per c.mm. They remained more or less at this level up to the time of the last puncture. Sugar was absent from the first specimen of fluid obtained and remained absent until that obtained on the 17th; thereafter no observations were made; the chlorides on first examination were 0·66 per cent.; by May 13th they had fallen to 0·59 per cent.; by the 16th they had risen to 0·61 per cent.; thereafter they rose slowly and at the time of the last puncture on the 25th were 0·63 per cent.

From the end of the second week the temperature fell gradually; it took two weeks for the range to fall within normal limits; by this time the patient was obviously on the way to recovery. He was well enough to leave the nursing-home 28 days from the time of his admission.

In September the patient went for a pleasure cruise, during which he apparently took advantage to the full of all the available means of diversion; he returned to his business on the Stock Exchange at the beginning of October. His health is now excellent but temper very bad; he complains only of a continuous annoying pain over the coccyx.

DR. HARWOOD LITTLE'S CASE

The patient, a boy aged 8 years, was seen by his doctor on Feb. 16th, 1933, with slight pyrexia, coryza, and sneezing, the condition being apparently influenzal. On the 18th his morning temperature was 102° F.; he complained of no pain and the evening temperature was normal. During the night he had acute pain in left ear. Feb. 19th: morning temperature 105°. Surgeon called in, who lanced the tympanum and released a little pus. Feb. 20th: ear quite clean, but morning temperature 105°.

I saw the child for the first time that evening. There was neither headache nor vomiting, but flexion of the neck caused pain in the upper dorsal region; there was a doubtful Babinski in the right side, and a distant suspicion of a positive Kernig's sign. Lumbar puncture produced 22 c.cm. of clear fluid under pressure and examination of the fluid gave the following results. Cells: 10 per c.mm., of which 60 per cent. were polymorphonuclears and 40 per cent. endothelial cells. No small lymphocytes were seen, and no micro-organisms were found in the stained deposit. Globulin: slight but distinct increase. Protein: 45 mg. per 100 c.cm. Sugar: 25 mg. per 100 c.cm. Chlorides: 720 mg. per 100 c.cm. The fluid was plated at the bedside on to warm Fildes's medium and on to warm blood agar. Both plates gave a sparse growth of a Gram-negative bacillus morphologically of Pfeiffer type. It survived one subculture, and then died in spite of strenuous efforts to keep it alive. At the time of lumbar puncture a leucocyte count showed: white cells 59,600 per c.mm.; polymorph neutrophils 85 per cent.; eosinophils 0 per cent.; basophils 0 per cent.; lymphocytes 10 per cent.; and monocytes 5 per cent. There were many immature neutrophils and some metamyelocytes.

Feb. 21st: morning temperature 105° and evening 103°. Feb. 22nd: white cells, 15,500 per c.mm., with 76 per cent. neutrophils and no eosinophils. From Feb. 23rd onwards the temperature was normal. The patient left the nursing-home ten days later, and has been in perfect health since.

These two cases were communicated to the discussion on the prognosis in meningitis held at the meeting of the Association of Clinical Pathologists on Jan. 27th last.

EPIDERMOLYSIS BULLOSA WITH PSORIASIS

By A. G. Smith, M.D. Glasg., F.R.C.S. Eng.
CONSULTING DERMATOLOGIST, NORFOLK COUNTY COUNCIL

Epidermolysis bullosa is a decidedly rare disease, and the combination of epidermolysis bullosa and psoriasis is still more rare.

The patient, whom I first saw seven months ago, was a little boy of seven, the *only* son of first cousins. A maternal aunt suffered from psoriasis, but otherwise there was nothing of note in the family history. The child was mentally alert.

The mother, an intelligent young woman who had been a school teacher before marriage, stated that she first noticed something wrong with the child's skin a few months after birth. The most trivial injury produced a blister which burst, left a raw area, and in a fortnight or so healed with the formation of a scar. The skin seemed to be excessively vulnerable and responded with a blister to the slightest stimulus. A year ago she first noticed a psoriasis patch on the healed scar of an epidermolysis bullosa lesion on the left knee, and since then many patches of psoriasis had arisen. When I saw the child he presented a typical picture of severe epidermolysis bullosa—the pemphigus successif à kystes épidermiques of Darier. The dorsa of the hands and fingers, the elbows, knees, and feet were the areas most severely affected, but there were healed lesions on the trunk and on the ears. His markedly sunburnt skin was speckled in these sites with thin white scars, amidst which were numerous epidermal cysts. Here and there raw lesions showed red, and numerous recent bullæ, some containing blood, were present. The nails of the fingers and toes were reduced to shapeless knobs of horny material; the teeth were decidedly carious. The psoriasis patches were quite typical and were disposed on the knees, elbows, and back in guttate formation.

I was hesitant about using any of the stronger medicaments for the psoriasis in view of the susceptibility of the skin to any injury, but ¼ per cent. cignolin in ung. lanæ co. over a localised area to start with and subsequently on all the psoriasis lesions removed that disease. At the same time I tried the effect of calcium and parathyroid on the epidermolysis bullosa, with little apparent benefit up till the present time.

There are two points of interest in this case apart from the superimposition of psoriasis. The first is that there is no evidence of hereditary affection with regard to the epidermolysis bullosa; this is unusual. I have been at some trouble in investigating the family history of the child reported here, but the little patient appears to be an isolated sufferer in his family. The second feature of interest is in the consanguinity of the parents. G. B. Dowling has met with a similar phenomenon, which he mentioned in a discussion at the Royal Society of Medicine in December, 1932; and later (October, 1933), at the same place, Twiston Davies showed a case of epidermolysis bullosa in which the parents were first cousins.

Norwich.

SEROLOGICAL DIAGNOSIS OF LATENT MALARIA

By E. D. W. Greig, C.I.E., M.D., D.Sc., F.R.C.P. Edin.
LIEUT.-COLONEL, I.M.S. (RET.); LECTURER IN TROPICAL MEDICINE, EDINBURGH UNIVERSITY
C. E. van Rooyen, M.B., Ch.B. Edin.
HALLEY STEWART RESEARCH FELLOW, DEPARTMENT OF BACTERIOLOGY; AND
E. B. Hendry, B.Sc.
CHEMIST, DEPARTMENT OF THERAPEUTICS

A. F. X. Henry has demonstrated [1] the property of malarial sera to flocculate solutions of iron methyl-arsenate and melanin pigment contained in ox choroid membrane. The former test he termed "ferro-flocculation"; the latter, which was found to be more sensitive, "melanoflocculation." Henry maintained that the phenomenon was due to the interaction of melanin pigment, which behaved as an antigen, and a corresponding antimelanagglutinin developed in the sera of malarial subjects. He regarded the reaction as specific for malaria and of value in the recognition of the latent infection when parasites were absent in peripheral blood. Several continental workers have confirmed [2] the latter observation and we have obtained similar results.

A number of difficulties have however been encountered owing to the unsuitability of crude aqueous suspensions of ox choroid membrane for use as antigen, arising from its instability and the large amount of ox tissue derivatives contained in it other than melanin pigment. The test as employed by

[2] See Greig, E. D. W.: Trop. Dis. Bull., 1934, xxx., 483.

Henry merely signifies that the serum examined has or has not agglutinated the antigen in a single low dilution. No provision was made for assessing the degree of positivity exhibited by different sera or the same specimen at various stages during the course of an illness. We have attempted to overcome these difficulties by the substitution of human hair for ox choroid membrane as a source of pigment, and by alterations in technique.

TECHNIQUE OF THE NEW TEST

The melanin pigment solution is derived from human hair by hydrolysis with 50 per cent. HCl, followed by concentration in vacuuo and purification by dialysis in a collodion membrane. This has been found to give a pure and stable suspension of pigment. A set of nine dilutions of patient's serum is prepared ranging from 1 : 2 to 1 : 512 in distilled water. To each is added an equal volume (0·4 c.cm.) of pigment solution, and the series is incubated at 37° C. for 5½ hours before the reading is taken. Positive results are observed as white granular precipitates forming at the foot of the tube; the degree of positivity is determined by noting the highest dilution of patient's serum showing precipitation.

The rise and fall of the reacting principle in human malarial sera with melanin pigment may thus be quantitatively ascertained during an attack. The method was tested on benign tertian infection induced in cases of G.P.I. Preliminary observations showed that the reaction appears about the 5th–7th day following infection, although no parasites may be seen at this stage and the patient is afebrile. The maximum titre of 1 : 128 is reached about the 4th week and then rapidly declines following the administration of drugs. Control tests on 129 different non-malarial sera gave only 2 non-specific positive results.

It is probable that the phenomenon is not due to the interaction of antigen and antibody, for it can be shown that positively reacting sera may be inactivated by heating to 55° C. for half an hour and that the repeated immunisation of rabbits with melanin pigment fails to produce an agglutinin response. The occurrence of a reaction with positive sera and dioxyphenylalanine shows that the reaction is due to the melanin and not to any other substance.

Observations on the lipoid phosphorus content of the serum during the course of the infection show that its amount tends to vary inversely with the reacting titre of the serum to melanin pigment. We suggest that the term melanoflocculation test should be dropped and melano-precipitation reaction substituted.

These findings were submitted to a meeting of the Edinburgh branch of the Royal Society of Tropical Medicine and Hygiene on May 15th, 1934, and a full account of them will appear in the July issue of the *Transactions* of the Royal Society of Tropical Medicine and Hygiene.

MEDICAL SOCIETIES

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY

PROSSER WHITE ANNUAL ORATION *

Dr. J. M. H. MACLEOD, the president of the society, took the chair on June 27th when the annual oration was delivered by Dr. WILLIAM ALLEN PUSEY, emeritus professor of dermatology in the University of Illinois.

The PRESIDENT said that in 1921 Robert Prosser White established a Trust Fund to provide an honorarium for an annual oration on the progress of dermatology, the orator to be selected by the council of the St. John's Hospital Dermatological Society. It had been laid down in the original deed that the name of the founder should not be revealed until after his death. Prosser White had died in January of this year, and the lectureship was now known as the Prosser White Oration.

Dr. PUSEY took as his title

Disease, Gadfly of the Mind

He devoted special attention to the stimulus of skin diseases in the development of the mind. Socrates, he recalled, had in the deepest seriousness emphasised his function of intellectual gadfly as his great service to the Athenians, a function placed upon him by God and so important that he claimed the favours reserved for Athens' worthiest citizens. The human mind had to develop itself, and its making was not a psychological or a physiological study but an historical one. The need to surmount the difficulties of life had always been the spur that had urged man on to intellectual as well as to physical effort. In that sense man's troubles had made him. Few incentives to thought had earlier influenced or more constantly prodded man in his progress than the injuries, pains, and illnesses that had beset him. Hippocrates had recognised this. The early efforts of man to find relief from his miseries had done a great deal more than gradually accumulate empirical knowledge; they had begun his training in technical skill. From the earliest records medicine had been one of the chief concerns of the mind. The greatest heights of early independent thought had been reactions to the study of disease. From every point of view disease had been one of the greatest gadflies to scientific thought. Disease and its student medicine could properly claim to be among the great forces in the evolution of the human mind.

Skin diseases and dermatology could take a very large part of the credit of medicine, for they had constituted one of its major interests from the very beginning. Indeed, when civilisation emerged from the stage of history man had already been considering not only the diseases of the skin but also its care and beautification. The best illustration of the persistence of vitality of medicine in the Middle Ages was furnished by dermatology. At that time eight diseases had been regarded as contagious and five were predominantly skin diseases: bubonic plague, consumption, epilepsy, scabies, erysipelas, anthrax, trachoma, and leprosy. Leprosy had been largely responsible for the growth of hospitals and had given a new impetus to the objective study of disease. Since the diagnosis of leprosy changed the civil status of its victims, it was a matter of great civil importance. There was much evidence that the study of leprosy brought dermatology and general medicine to a higher plane of knowledge in this period. De Mondeville's description of the facies of leprosy was notable for accuracy of observation, vividness of description, selection of essential features, and evidence of a mind thinking in objective terms. By the end of the fifteenth century leprosy had been rapidly dying out, but it had been succeeded by the new plague of syphilis, which had done more than anything else to stimulate the objective study of diseases.

LANDMARKS OF DERMATOLOGICAL PROGRESS

A significant example in the last three hundred years was the work of Ramazzini on occupational dermatoses. To the list of things which the physician should inquire as laid down by Hippocrates, he added one more: "What trade is he of?" Another striking illustration was the description of chimney sweeps' cancer of the scrotum by Percival Pott in 1775. This was the pioneer landmark in the history of our knowledge of the causes of cancer, drawing attention both to tar and to long-continued irritation. In the skin, as nowhere else, was given the opportunity for the recognition and study of cancer in its early stages. Another landmark was the beautiful demonstration by Bonomo of the causal rôle of the itch mite in scabies. Ramazzini and Bonomo had been among the first to demonstrate clearly the direct action of local causes in the production of inflammatory diseases, and their work was an epochal step in the advance of knowledge of pathology.

---

* This oration will be published in full in the Proceedings of the Society.

The skin was a happy hunting-ground for the investigation of the facts, particularly the minute facts, of biology and medicine. Unna had pointed out in 1896 that this exceptionally favoured position of the dermatologist brought with it a serious responsibility: to analyse the histological details closely and not to rest until macroscopical and microscopical appearances had been brought into agreement. Cutaneous pathology, he had observed, must have a great bearing on general pathology. A good modern illustration of this was Sir Thomas Lewis's use of the cutaneous circulation to illustrate methods of physiological investigation and interpretation of the phenomena of the peripheral circulation and small blood-vessels in general. Another example was Cockayne's study of abnormalities of the skin and its appendages in the light of genetics. The successful study of the finer details of tissues dated from the perfection of section cutting and differential staining by Carl Weigert, who at first applied his technique to the study of the small-pox eruption. Unna had carried staining methods still further and incidentally had discovered plasma cells and described other new forms of connective tissue cell.

The general ideas of contagion and its causes were likewise in great part the result of the study of dermatology. Fracastor, with his strong interest in syphilis and skin diseases, had developed the idea that contagious diseases were due to micro-organisms. Hauptmann of Dresden and Langer of Leipzig had suggested independently in the seventeenth century that all skin diseases were of parasitic origin. The first fact in human microparasitology was Schönlein's discovery of the organism of favus. The demonstration by Hansen of the bacillus of leprosy in 1871, eleven years before the discovery of the tubercle bacillus by Koch, was one of the earliest observations of pathogenic bacteria.

Studies of the skin manifestations of exanthemata had profoundly influenced modern conceptions of infection and immunity. Fuller in 1730 had clearly indicated the specificity of infection. The skin had likewise been the site of the first studies of what was now called allergy and sensitisation. Jenner had pointed out the allergic relationship between small-pox and vaccinia, and a group of Englishmen and Scotsmen had made a remarkable series of studies on the skin towards the end of the eighteenth century. The acquired tolerance of the skin to the bites of parasites and various insects had early led to the production of artificial immunity and later to the study of immunity generally. The critical tests of immunity to-day had developed from investigations on the skin, and their practical application was made in the skin. The skin was said to possess a degree of immunity more than ten times as great as that of muscle, brain, or blood. It was quite possible that the studies of the cutaneous manifestations of allergies might open up new chapters in the knowledge of the pathogenesis of important diseases of internal structures.

From time immemorial the influence of the general health on the skin had been emphasised; perhaps over-emphasised, but the influence of the skin on the general health was a relatively new conception. It performed chemical functions of vital importance, particularly under the influence of light.

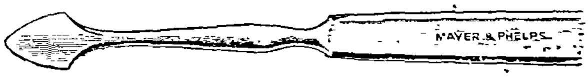
Knowledge of the relation between the skin and the ductless glands went back at least a century, to the time when Addison described the disease which bore his name. The skin itself was now being recognised as an organ of metabolic activity and Kreidl had even suggested that it had an internal secretion. Hertslet had suggested that it might be a hormone balancer. The endocrine and metabolic functions of the skin had been used empirically by Finsen.

Dr. Pusey's thesis, he said in conclusion, was that diseases had been among the greatest incentives in the making of the mind and that few diseases had as great an influence as those of the skin. He did not believe that this excursion was a fanciful or trivial speculation. There was nothing more important in the evolution of civilisation than those relatively few goads of the mind which had first lifted the human race out of barbarism. The great rôle that skin diseases had played in the making of the human mind was the great challenge to dermatology to be worthy of its heritage and of its great opportunity.

NEW INVENTIONS

A KNIFE FOR SUBMUCOUS RESECTION OF THE SEPTUM

THE knife, here illustrated, has been designed and used by me for the submucous resection of the septum. It is double edged at the sides and somewhat oval-shaped at its extremity. The incision in the mucosa begins in the uppermost angle of the nostril and is continued in one sweep right down to the floor of the nose. The lower cutting edge starts the incision, about half-way down the septum the extremity of the knife takes it up; then the upper cutting edge is engaged, and finally the extremity is again used to complete the incision on the floor of the nose. The advantages claimed are: facility of producing the incision with one single sweep and the impossibility of penetrating the septum, while it takes the place of a sharp dissector to detach the muco-perichondrium.



Mayer and Phelps, of 59-61, New Cavendish-street, W., are the makers of the instrument.

ARTHUR MILLER, F.R.C.S. Edin., D.L.O.

A NEW MENTAL HOSPITAL.—Mr. L. G. Brock, chairman of the Board of Control, laid the foundation-stone, last week, of a new mental hospital at Runwell, near Wickford, Essex, the former property of the corporations of East Ham and Southend. It is placed upon a site of 500 acres, and will eventually accommodate 1085 patients; at present it is being designed for 875. There will be a large nurses' home, and on a portion of the site there will be provisions for "parole" patients. The total cost will be £462,000.

REVIEWS AND NOTICES OF BOOKS

Forty Years of Psychiatry

By WILLIAM A. WHITE, M.D., Sc.D. New York: Nervous and Mental Disease Publishing Co. Pp. 154. $3.00.

Recent Advances in Psychiatry

Second edition. By HENRY DEVINE, M.D., F.R.C.P. London: J. and A. Churchill. Pp. 364. 12*s.* 6*d.*

1933 Year Book of Neurology and Psychiatry

Neurology. Edited by PETER BASSOE, M.D. *Psychiatry.* Edited by FRANKLIN G. EBAUGH, M.D. Chicago: The Year Book Publishers. 1934. Pp. 471. $2.25.

THE remarkable development of psychiatry during the last half century may be appreciated when one finds it summed up in the life and comments of an observer who has acted a prominent part in the promotion of this development. But the range of psychiatry is now so wide that the interests of even an unusually experienced man like Dr. White are of necessity limited. It is instructive to read first his account of what has happened in the United States, especially in regard to mental hospital administration and in the psychological approach to mental disorder; and then to go through a comprehensive survey of the present trends and knowledge, such as Dr. Devine supplies, and finally to glance at a cross-section of the current literary output in the 1933 Year Book of Neurology and Psychiatry.

Dr. White entered psychiatry when it was remote from general medicine, and he found the care given to the insane deplorable. He became superintendent of an important mental hospital (where there are at present 5000 patients), and he not only built it up with extraordinary ability but was among those in America who most energetically gave effect to the prevailing ideals—that mental disorder should be regarded as an illness, treated and investigated, given a large place in medical education, and brought into relation with other human problems, especially social ones. It might be supposed that the qualities requisite for the guidance of such an institution as St. Elizabeth's Hospital would hardly be associated with an ardour and receptivity for new, highly unorthodox ideas, but Dr. White early opened his mind to psycho-analysis and has espoused it with few reservations; he is one of those who see in it the most fruitful influence in modern psychiatry so far, and the most promising of further advance.

Dr. Devine gives a somewhat different picture. It is not that he is antagonistic; he is indeed sometimes so anxious to do justice to this school of thought that he falls into inconsistency, and one of the few points deserving of extension in his admirable book is the tacit assumption that there is practically no psychopathology other than that of the analysts. But since his task is to cover the whole field of psychiatry, he necessarily devotes much space also to those biological, metabolic, clinical, and experimental studies which have done so much to advance our knowledge. The three new chapters introduced into the second edition are concerned with heredity and with some clinical and chemical correlations. His fair presentation constantly reminds one how many are the aspects of this field, even when it remains strictly medical, and how difficult it is to tell which line of study will yield most, and which has fallen victim to bias, irrelevance, licence of hypothesis, or carelessness in verification.

Dr. Ebaugh's summary of current literature of the year is unfortunately heavily weighted on the side of American studies in what one may call the nebulosities of psychiatry—education, mental hygiene, social psychiatry, the psychiatric attitude and so forth; it has also the defect of being somewhat uncritical and of being written in a barbarous, careless English. It is useful in so far as it shows up the uncertainties in psychiatry, where so much is clinically fixed and useful and so little fundamental knowledge established. The contrast with neurology, the year's work in which is well presented by Dr. Bassoe in the same volume, is striking. Some might urge in excuse that neurology is a finite study, while psychiatry is living and in flux. But such a view would not only be unjust to neurology, but would ascribe to growth and vitality in psychiatry what is at least in part only evidence of a myopic and immature zeal on the part of workers with more knowledge of a special mode of investigation than of the actual material and problems of mental disorder to which they would apply it. It must be admitted that psychiatry needs a more complete background of accepted fact before scientific work can be readily communicable and discussion on it profitable.

Die Parasagittalen Meningeome

By Dr. H. OLIVECRONA, Stockholm. Leipzig: Georg Thieme. 1934. Pp. 144. M.24.

THE meningiomas form about 15 per cent. of all intracranial tumours and usually grow from an accessible part of the dura mater. Their diagnosis and accurate localisation are therefore of considerable importance. Dr. Olivecrona has presented in this monograph an elaborate study and analysis of his observations in 34 examples of parasagittal meningioma. He defines these as tumours springing from the wall of the superior longitudinal sinus alone, or from a combined site consisting of sinus wall and the adjoining dura covering the cerebral convexity. He includes also meningiomas of the falx both because these spring also from the sinus wall in many cases and because they present similar problems in operative technique.

The author divides his cases into three clinical groups according to whether the tumour arises from the anterior (10 cases), middle (14 cases), or posterior (3 cases) third of the sinus wall. In 7 cases the tumour was attached to the falx. A syndrome is outlined for each of the three groups, an outstanding feature in all groups being a long history. The symptoms in tumours in the anterior third are, as a rule, initiated by headache. The frequency of psychic disturbance of variable kind and intensity is stressed; such a disturbance was present in all except one example. Contralateral facial weakness, bilateral papillœdema, and hyposmia or anosmia are also common. Patients with tumours of the middle third of the sinus tend to have motor and sensory disturbances. Jacksonian attacks originating in the lower extremity are an outstanding feature. Psychic changes are rarer than in the first group, and general pressure symptoms develop late. Meningiomas of the posterior third of the sinus are seldom seen. Here hemianopia is a salient feature and, if the tumour is left-sided, sensory aphasic symptoms with alexia and agraphia will probably be found. The less constant signs and symptoms and the main points of differential diagnosis are discussed in reference to all the groups. Tumours of the falx are classified according to the third of the sinus from which they originate.

Many interesting points in the morbid anatomy of the tumours emerge from this study. It is remarkable that Olivecrona has encountered a bilateral tumour in as many as 13 of his cases; the tumour seems to have started on one side and to have extended across the midline either by a process of invasion of the sinus wall or by hooking underneath the free lower edge of the falx. The mechanism of sinus invasion is described and illustrated by a number of microphotographs, which make it clear that the wall of the sinus rather than the lumen is invaded. Even when the sinus is almost completely obliterated the tumour is separated from the lumen by the intimal endothelium. This process appears to be only an exaggeration of the normal tendency of the arachnoid cells to become invaginated into the dural sinuses, forming the so-called arachnoid villi.

This monograph is well balanced and complete from all aspects except that of histological pathology. It is promised in the text, however, that this subject will be dealt with in the near future by Prof. Bergstrand.

Principles of Gynæcology

Fourth edition. By WILLIAM BLAIR-BELL, B.S., M.D. Lond., F.R.C.S. Eng., F.C.O.G., Emeritus Professor of Obstetrics and Gynæcology in the University of Liverpool. Revised and largely rewritten with the assistance of M. M. DATNOW, M.D., F.R.C.S. Edin., M.C.O.G., and ARTHUR C. H. BELL, M.B., F.R.C.S. Eng., M.C.O.G. London: Baillière, Tindall and Cox. 1934. Pp. 848. 35*s.*

THIS text-book has been written primarily for the use of students, for whom Prof. Blair-Bell has set a high standard of scientific training and intelligence. He states definitely that the book does not pretend to provide material for the training of gynæcological specialists though it may well serve as a groundwork for students with this aspiration.

The advances made in gynæcological knowledge since the publication of the last edition have been recorded in this edition. Completely new sections on such subjects as physiological phenomena dependent upon internal secretions, and on certain pathological lesions—for example, endometriomata and ovarian neoplasms—have been supplied. There is also a full review of present-day knowledge of the nature and treatment of malignant disease. New chapters are those on the history of gynæcology and on the sociological questions of contraception and therapeutic abortion, and other ethical and medico-legal considerations which may arise in gynæcological practice. The 144 pages devoted to the section of operative procedures cover much ground, and contain such detailed illustrations of the operations described in the text that the reader can follow the steps of an operation by a study of the drawings alone. Indeed, the illustrations throughout the book are unusually apt. Of the two appendices, one deals with post-operative exercises and the second with the ætiological classification of the causes of certain gynæcological symptoms and manifestations; these should be useful not only to the student reading for an examination, but also to the practitioner responsible for a patient suffering from a gynæcological defect. The index is satisfactory and the printing excellent.

This is a text-book that has definitely made a contribution to the teaching of gynæcology.

Dynamics of Therapy in a Controlled Relationship

By JESSIE TAFT. London: Macmillan and Co., Ltd. Pp. 296. 12*s.* 6*d.*

THIS is an obscure work. The detailed accounts of the cases are interesting and instructive in themselves, and, like the author, we are uncertain as to how the results were achieved. The name relation therapy which she gives to her methods is not very illuminating. All treatment by psychotherapy is relational and depends upon transference. Where her method differs from Freud's is in the insistence on the present situation; resolution is achieved not by reductive analysis, but by the resolution of fear which paralyses the ability to see life as a whole. This fear motive is held to be ultimately derived from its prototype which is the traumatic experience of birth, according to the ideas of Otto Rank. Unfortunately, in the author's attempt to clarify by explaining the dynamics of therapy, she becomes completely submerged in a sea of words.

Eclampsia in England and Wales

By NORMAN PORRITT, M.R.C.S., L.R.C.P., Consulting Surgeon, Huddersfield Royal Infirmary. London: Humphrey Milford, Oxford University Press. 1934. Pp. 88. 5*s.*

THIS small book is written in support of a theory that an insidious form of lead poisoning plays a definite part in the ætiology of eclampsia.

Dr. Porritt first called attention over 40 years ago to the possibility of this form of lead poisoning and he quotes many examples of effects which he attributes to it apart from pregnancy. His theory of its significance in the causation of eclampsia is based largely on a statistical study of maternal mortality figures and on the similarity between the lesions of lead poisoning and those of pregnancy toxæmia. After explaining the cumulative effects of small quantities of lead particularly on the pregnant woman, he points out that a high maternal mortality from diseases other than sepsis coincides with a soft water-supply such as is found in North Wales and the North of England. In these areas, which show a high maternal mortality-rate, there is no increase in the deaths from sepsis, whereas the death-rate from other causes is excessive.

The author has long retired from practice and has not the facilities for proving or disproving his theory. On the evidence put before him the reader cannot fail to be impressed with the reasonableness of the argument and of the necessity for an extensive investigation in a soft water area where eclampsia is common. An explanation of the high maternal mortality in the "black areas" has been offered which can only be investigated on the spot.

British Journal of Children's Diseases

IN the issue of April–June (Vol. XXXI.) Dr. R. F. Guymer contributes a paper entitled Tonsillectomy: Before, During and After, based on a study occupying nearly six years of 182 cases living in the Kingston-on-Thames district. The dissection method was used in each case. The following points are considered: the presence or absence of subjective symptoms referable to the throat, the state of nutrition of the patients, and the average number of professional visits paid to each patient during each year before and after the operation. In no case did the tonsils show any signs of recurrence, and it is now two years since the last operation was performed.—Dr. F. Parkes Weber contributes Further Remarks on Cystic Dilatation of the Common Bile-duct as a supplement to his paper in the previous issue.—In an article on Cases of Median Nerve Palsy Produced by Attempted Intravenous Injections of Calcium Chloride, Dr. Harley Stevens records two cases in which the median nerves had been injured as the result of intravenous injections of calcium chloride when the median basilic vein was utilised. After discussing the manner in which the injury was produced and the regional anatomy he makes suggestions which should enable similar results to be avoided in future.—In his paper on Some Pædiatric Eponyms. v. Young's Rule, Dr. W. R. Bett gives a concise account, illustrated by a portrait, of the life and work of Dr. Thomas Young, who, in his Introduction to Medical Literature published in 1813, laid down the rule regarding the dosage of medicines in childhood.—The abstracts from current literature are devoted to urogenital diseases.

NATIONAL PHYSICAL LABORATORY

THE annual inspection of the laboratory took place on June 21st. As usual the arrangements made to explain the exhibits to visitors were admirable, highly technical apparatus being demonstrated with such skill that its object, if not its mechanism, became clear to those without specialised training. We select from nearly a thousand exhibits a few which show the wide range of work in progress in the various departments of the laboratory under the general direction of Sir Joseph Petavel.

X Ray and Gamma Ray Dosage.—The method used by the earlier workers, and still in wide use for measuring the quantity or "dose" of X rays given to a patient, was to expose a barium platinocyanide pastille to the rays; this pastille changes colour under their influence. Doses which give the same colour change do not always, however, correspond in their medical effects, and a few years ago a more precise definition of X ray quantity was adopted internationally, in which the electrical conductivity produced in air by the rays was taken as basis. Difficulties presented themselves, however, in the design of apparatus for measuring X rays in the new unit, the "röntgen (r.)." The National Physical Laboratory has now developed a standard apparatus, obtainable in portable form and giving results correct to 0·5 per cent.

The gamma radiation from radium differs from X rays only by its great penetrating power consequent upon its shorter wave-length. The difficulties of measuring these rays in r. units are greater than in the case of X rays, but experiments to this end are in progress.

New Acoustics Laboratory.—This laboratory of the Physics Department is now equipped and was on view. It contains a reverberation room and a pair of transmission rooms together with associated measurement rooms, and provides unique facilities for the study of the absorption and the transmission of sound. The rooms, which are asymmetric both in plan and elevation, will facilitate the study of noise transmission and abatement in relation to the design and construction of walls and floors of modern buildings, and the testing of acoustical absorbents.

The Measurement of Colour.—A preliminary model was shown of an instrument which can determine the colour of a specimen without any colour-matching by the eye of an observer. The eye is replaced by a photo-electric cell, in which an electric current is set up by light falling on the cell.

In the system of colour measurement developed at the laboratory—and now adopted internationally—any colour is expressed by three numbers. These numbers may be regarded, in non-technical terms, as measures of the proportion of redness, greenness, and blueness which contribute to the actual appearance of the colour.

In the new instrument, the photo-electric cell "sees" the colour under test through three coloured screens in succession, and the current which it generates is noted in each case. The relative magnitudes of these currents give the three numbers which measure the colour on the international system.

The new instrument is specially useful for rapid determinations of the comparative values of similar colours.

Prevention of Collisions during Fog at Sea.—An instrument has been devised at the laboratory which will give warning on board ship of the approach of other ships in fog.

Although this is actuated by wireless signals, its operation does not prevent ordinary wireless telegraphy, even on the same wave-length. The indicator consists of a glass disc marked "Fore and Aft," "Port and Starboard." Wireless signals from a neighbouring ship cause a luminous line to flash out on the disc in the direction of that ship. If the neighbouring ship is approaching the observing ship the length of the line increases; if the ships are heading for a collision the direction of the line will remain fixed, and the course of the observing ship may be altered to avoid danger of collision.

The device will show the exact direction of a neighbouring ship in foggy weather at any distance up to ten miles.

Automatic Steering of Ships.—Another novel and useful instrument developed in the radio department indicates automatically deviation of a ship from a set course. If the deviation is to starboard a green light is lit, if to port, a red light, while a white light indicates that the set course is being accurately followed.

This "compass" employs an entirely new principle. A jet of electrons is shot out from the filament of a cathode ray oscillograph, and is deflected to the east by the earth's magnetism. Two glass thimbles are disposed so that when the ship is on her set course the electron jet is divided equally between them. As the ship deviates from her course to port or starboard the electron jet is deflected so that it enters only one of the thimbles, and the red or green light is brought into circuit according to which thimble is receiving the jet, thus showing the helmsman which correction to apply.

Known methods of remote control can be incorporated to effect automatic correction of the course.

Measurement of Length in Terms of Light.—The completed apparatus designed and constructed at the laboratory for measuring the yard and the metre in terms of a wave-length of light was on view.

The lengths of the fundamental standards of the country have now been determined in terms of a wave-length of red light. This constant is itself only about one forty-thousandth of an inch long, but it can be measured so precisely that it enables us to control the yard to less than one-millionth of an inch. The important point as regards the use of a wave-length of light in this way is that its length is invariable and can always be reproduced.

Proposals have been made to define the standards of length of the world in terms of a wave-length of light, and international agreement is being sought to this end.

Effect of Wheels on Roads.—Suitable apparatus for measuring and recording road transport forces has been designed, and it is proposed to fit this apparatus to a series of vehicles. The first vehicle, a heavy six-wheeled lorry, ready for sending on the road, is exhibited.

BODY-BUILD AND FUNCTIONAL EFFICIENCY

CRITERIA of physical efficiency provide a perennial topic for discussion and an opportunity for ventilating opinions which are apt to be surprisingly divergent. Those interested in the subject may recall the correspondence in the *Times* in March of last year in reference to tests proposed for selecting candidates for the crews in the University boat-race; a correspondence to which several medical men with personal and clinical experience contributed. In general it was concluded that, so far, no method of estimating exceptional physical efficiency can be accepted as satisfactory. In our present issue, Group-Captain TREADGOLD returns to this problem and applies the results of a large series of observations to a consideration of the relationship between efficiency and body-build, more particularly in the young male adult. Functional efficiency in this connexion he reviews under three headings: . the capacity to endure severe or prolonged physical stress; the capacity to endure severe or prolonged mental stress; and the degree of resistance to disease. Body-build is an expression of the relationship between age, height, and weight, and is simply recorded as weight, with the expressions under-weight and over-weight according to the variations below and above the standards authoritatively accepted as normal.

The accepted entrants to the Royal Air Force fall into two distinct groups, according to whether they are likely to be trained for flying or not. The future pilots form a specially selected group and undergo a much more searching medical examination than the ordinary "airmen" recruits. From TREADGOLD'S graphs the remarkable fact appears that whereas in the latter (non-flying) group the number of under-weight men is double the number of over-weight, among the pilot recruits the figures are almost exactly reversed. This difference may be explained on the principle that the higher standard of fitness demanded in a prospective pilot results in the rejection of many who would be accepted under the less exacting requirements of general service. In addition, the candidates for flying are for the most part from a higher social class and have enjoyed dietetic and hygienic advantages during childhood and adolescence which make for a better physique. To investigate the relation, if any, between body-build and capacity to endure severe or prolonged physical strain, observations were directed to the airmen who competed in the Royal Air Force athletic championships and in such analysis a further differentiation was made into four groups: those competing in the tug-of-war contests, those in field events, those in the shorter distances on the running track from 100 yards to a quarter mile, and those in the longer distance events. Contemplation of the physique essential for such a contest as a tug-of-war prepares one to expect an overwhelming preponderance of the over-weight class. This feature is also prominent in the field events competitors, doubtless from the large contribution afforded by the "strong men" who put the weight and throw the discus and javelin. A like preponderance is evident among the sprinters, a type of athlete in whom a powerful musculature and well-developed frame are essential for the explosive maximal effort that must be put forth for a brief period. But among the long-distance runners extra body-weight must be a serious handicap, for here conservation of energy is all-important in contrast to the prodigal expenditure of the sprinter to whom expense (so to speak) is no object. Although, as has been pointed out by Dr. ADOLPHE ABRAHAMS in his investigations among the leading athletes of the world, there are a few striking exceptions to this rule, the body-build of the marathon runner is often conspicuously poor when one considers the work which is demanded. In relation to extreme physical exertion of another kind it is interesting to note that all the approved personnel of the recent Mount Everest Climbing Expedition were under-weight—a rather unexpected revelation considering the peculiar nature of the exertion with its associations apart from purely physical strain. It would probably be found that these highly specialised climbers, notwithstanding their body-build, had a large vital capacity as well as some special indefinable attribute.

The relationship of body-build to disease has an even closer application to medical work. Group-Captain TREADGOLD classifies diseases under infective (principally pulmonary tuberculosis, chronic otitis media, and rheumatic carditis), non-infective (including epilepsy and digestive disturbances), and psychic disorders (psychoses and psychoneuroses). In all three classes the under-weight subject preponderates, more especially in the first. (These figures, it must be added, refer to the general service men and not to the pilots, who exhibit differences of susceptibility from the special character of their work. It will at once occur to the critical reader that there is some disparity between these conclusions and the universal practice of life insurance offices which view the under-weight applicant as a whole with greater favour than the over-weight, whom they consider likely to live less long. The suggested answer to this is that the poorer functional efficiency of the under-weight person encourages him to lead a relatively sheltered life, and that the accompanying tendency to arterial hypotension provides a consequent immunity to some of the cardiovascular catastrophes of later life. From the point of view of sickness insurance, however, the under-weight must compare unfavourably with the over-weight in his greater liability to disease—a fact to which companies which specialise in sickness policies have not, so far as we are aware, paid any particular attention.

the rest of us valuable assistance in making up our minds, by testing the reasons, so far as they are yet established, for taking one view or the other. The discussions are succinct. Sentiment and tradition will ever influence intelligence, and Heaven forbid that such influence should disappear as worthless, but it is good that its force should be corrected by argument, so that action may follow on what, at any rate for the time being, appears reasonable. We believe readers will see that in the debate published this week the opposing speakers are not so far apart in their teachings as would be suggested by the conversations of the public.

The contrasting of written views is just now a commonplace technique in detective fiction, and no apology is needed for allusion to the methods of this popular form of literary activity although serious matters are under consideration. It is understood that the greatest minds to-day seek relaxation in the pages of these stories, thus following Bismarck whose favourite author was Gaboriau—or so we are always informed. But more dignified and venerable authority can be cited for the method of dialectic comparison. It is the method of Socrates, who, while he left to his great disciple the writing and expansion of the ideas, conducted his own courses of verbal instruction by the balancing of pros and cons. *Taking either side, and regarding the putting of* questions and the supplying of answers as the one way to advance knowledge, he was able to cancel or modify opposing theories; and, while protesting against the pursuit of knowledge for its own sake, he strove to arrive at generalisations through the establishment of particular propositions. That is the spirit in which the problems which lie before medicine should be approached, and it is the spirit which is growing up among modern seekers of the truth; and they, as we were reminded by a recent Harveian orator, are following, consciously or not, Greek example.

Presentations of controversial issues, similar to that published this week, will appear in our pages from time to time as occasion suggests, and the information so afforded will show on what sound grounds medical men may differ, while holding similar ideals for the advancement of the truth.

ANNOTATIONS

HEREDITY AND DISEASE

THE Buckston Browne prize essay for 1932 has been published[1] in book form with a few minor alterations. It consists of four sections, dealing generally with the history of medical genetics, modern methods of study in human genetics, original data collected by the author to illustrate some of the principles enunciated in the preceding section, and, finally, the future of human genetics and the relation of medicine to eugenics. It is hardly an introduction to the study of human genetics which will make an appeal to the general practitioner of medicine, who would be mystified by a great deal of special terminology which the author is not at pains to explain. But the serious student of genetics will find it stimulating, for Dr. Penrose brings to his own subject an extensive knowledge also of algebra and of clinical medicine, besides a ready pen and much special erudition.

So far as human hereditary diseases are concerned, it covers a small field. The future of human genetics, we are led to suppose in the last chapter, is rosy. "One of the chief aims of human genetics is to identify as many as possible of the Mendelian characters of man and to allocate the positions of those characters on the chromosomes." This aim, the author thinks, will ultimately come near to realisation through the extensive use of laboratory methods, serological and chemical, such as those which have been employed to demonstrate the heredity of the blood groups. But what will be the benefit to medicine of the mapping of the human chromosomes? Not great, says Dr. Penrose, who belongs to the school which lauds the method of human genetics but disparages its possible results. Genetic methods, according to him, may be useful in reducing somewhat the incidence of dominant autosomal and sex-linked characters, which cause such grave diseases as epiloia, split hand, and Huntington's chorea—all rare, be it noted. "But generally speaking," he says, "it is unwise to be *unduly optimistic about the results of eugenic measures* in medicine." The general effect of the book is therefore somewhat disappointing. The principle of random mating is introduced with a flourish as "one of the most valuable concepts in human genetics." Yet the proposition, is admitted that "human beings do not mate entirely at random." Gentlemen, we have been reminded, prefer blondes. Jews like to marry Jews and Catholics Catholics. As a rule people marry into the same social class as themselves, this being arranged by the parents in France. Geographical propinquity also plays a part. And the situation among primitive tribes, with their systems of marriage taboos and exogamy, is even less favourable to the theory of random mating. In fact, in practice, though not in theory, human mating is anything but random. The introduction of the principle of random mating is followed in most books on human genetics with the emission of a cloud of mathematical confetti, by which the reader is so impressed (or stupefied) that he fails to see that, under a façade of flawless algebra, dubious premises are surreptitiously concealed. Dr. Penrose kindly spares us most of the algebra, which, in a book with a clinical orientation, is a good thing, seeing that the principle of random mating (or at least the algebra) is chiefly concerned with recessive and sex-linked rather than dominant abnormalities for the prevention of which, according to Dr. Penrose, little is to be expected from genetic methods.

Despite the relative uselessness of these methods in preventing disease the help of the medical profession is earnestly solicited in the preparation of authentic pedigrees, in order, presumably, that the human chromosomes may be mapped. If Dr. Penrose's low estimate of the clinical value of the results is correct, the medical profession might be justified in contending that its energies could be better employed; but in our opinion he is unduly pessimistic about the possible results of genetic methods in preventive medicine. *In fact some of his own researches, unquoted in this* book, suggest how they could profitably be used. To give only one example: they are applicable to the subcultural group of mental defectives, which, according to Dr. Penrose, comprise about a quarter of the total inmates of the Royal Eastern Institution.

[1] The Influence of Heredity on Disease. By Lionel Penrose, M.A., M.D. London: H. K. Lewis and Co., Ltd. 1934. Pp. 80. *5s.*

ANTIMONY IN ENAMELLED WARE

THE Ministry of Health has published a report[1] by Dr. G. W. Monier-Williams on the risks of antimony poisoning when enamelled vessels are used for the preparation or storage of food. Outbreaks of antimony poisoning have arisen from the preparation of lemonade in such vessels, whether real lemons were used or so-called lemonade crystals in which tartaric acid replaces the natural citric acid of the fruit. There is no reason except cheapness why antimony should be found in enamelled ironware, since oxide of tin is a better material for giving the enamel the desired opacity. Tin is, however, the most expensive of the base metals and the use of antimony in its place may lessen the cost by 3 or 4 per cent. (say ½*d*. in the shilling) which would hardly be a sufficient inducement to the purchaser if aware of the serious effects of antimony poisoning. It is clear, from the evidence adduced by Dr. Monier-Williams, that the trioxide, Sb_2O_3 is more dangerous than either the tetroxide Sb_2O_4, or the pentoxide Sb_2O_5. The trioxide or sodium metantimoniate, $NaSbO_3$, is the only compound actually used, but as the enamel is subjected to a high temperature in the process of fluxing it on the iron of the vessel, all three oxides may actually be found in the finished article and in fact were so found. The question of immediate interest is not how much antimony a glaze contains, but how much it is likely to yield to food or drink prepared or stored in vessels coated with it. Two classes of tests were therefore done on hollow-ware articles found to be made with antimonial glaze: (1) analysis of the glaze itself; (2) estimation of the amount of antimony going into solution after allowing hot 2 per cent. tartaric acid to stand in the vessel for one hour with occasional stirring. It is noteworthy that the amount of antimony dissolved from the glaze, whether expressed as volume concentration in the acid solution or as weight per unit of surface exposed to its action, bore no constant ratio to the total amount found in the glaze detached from the vessel. This is no doubt partly due to the fact that a variable amount of the undercoat, which does not contain antimony, is usually chipped off with the actual glaze. Of 11 enamels examined 2 contained less than 1 per cent. of antimony in all states of oxidation, 3 between 1 and 2 per cent., 2 between 2 and 3 per cent., 1 between 3 and 4 per cent., 1 between 4 and 5 per cent., and 2 about 6 per cent. One small jug containing less than 1 per cent. yielded no antimony to tartaric acid; a large jug containing 2·1 per cent. yielded 138 mg. per litre, or 15·65 mg. per square decimetre (this was one of a batch which had caused poisoning at a London hospital); whilst a pie-dish containing over 3 per cent. gave 79·2 mg. per litre or 9·45 mg. per square decimetre, the antimony extracted being mostly in the form of the poisonous trioxide. The effect of repeated treatments with acid was not studied and it is conceivable that as the surface became rough the area of exposure would be increased and more antimony extracted. Having regard to the cases of poisoning (though happily none proved fatal) the prohibition of antimony in all classes of hollow-ware which might be used for food does not seem unreasonable. Some firms have used antimony compounds which they believed to be insoluble, and in some cases the antimony seems to have entered the glaze as an unsuspected impurity. But this circumstance affords little satisfaction to people who have been brought almost to death's door.

MORTALITY FROM PERNICIOUS ANÆMIA

FROM time to time various workers have brought forward figures suggesting that the incidence of pernicious anæmia differs between races. In particular it has been stated that the disease is unduly prevalent in the temperate zones of North America, Northern Europe, and the British Isles. In the minds of other observers there has been considerable doubt whether race really does play any important part in the distribution of its incidence and mortality. A recent study by Dr. Richard Friedlander[1] of 500 cases admitted to the Peter Bent Brigham Hospital (Boston, Massachusetts) between 1913 and 1932 appears to favour the existence of national differences. Of all the patients admitted to the hospital during the period of the survey (over 80,000) 0·62 per cent. had pernicious anæmia; subdivision by nationality shows that over 1 per cent. of the patients from Canada, Sweden, and Denmark had the disease and over 0·7 per cent. of those from Ireland and England as compared with only 0·18 per cent. of those from Russia, 0·17 per cent. from Italy, and 0·06 per cent. amongst negro patients. The weakness of this type of evidence lies in the absence of all knowledge of the type of population from which the cases are drawn. Mortality from pernicious anæmia shows, as may be seen in the statistics of England and Wales, a steady and considerable rise with age and an appreciably higher incidence in the female sex. In other words a population consisting of persons in the older age-groups, or with a preponderance of females, will certainly show a higher incidence than a young population. If, for instance, the Russian patients in the hospital are drawn from a young immigrant male population, their incidence of pernicious anæmia is certain to be low. For a convincing solution of the problem case-rates at ages are essential; proportional rates such as those quoted above cannot be more than suggestive. That they may be fallacious is indicated by a comparison of the figures given by Friedlander for England and Scotland. Of the English patients admitted to the hospital 0·88 per cent. suffered from pernicious anæmia, while of the Scotch patients there were 0·43 per cent., or only half as many. Yet study of the death-rates given in the reports of the Registrars-General for England and Wales and Scotland shows that in fact the Scotch suffer consistently higher rates than the English at every age, and at all ages have a rate over 30 per cent. above that of England and Wales.

Such a complete reversal of the real position in this case makes the validity of the other national differences very doubtful. Friedlander's own opinion is that not only is predisposition to the disease racial in character but that it is largely confined to those individuals with a diathesis characterised by a fair complexion, light hair, blue eyes, and achlorhydria. It should be possible to collect satisfactory evidence on the importance of constitution. An analysis of 51 cases, 36 of which were autopsied prior to and 15 since the advent of liver therapy, showed no change since the introduction of this method of treatment in the weight of the liver, but the earlier group showed a greater weight of the spleen than those treated by liver. Of all cases treated with liver since

---

[1] Amer. Jour. Med. Sci., May, 1934, p. 634.

1926, about 11 per cent. were known to have died. The definite decline in mortality in this country that followed in 1928 the introduction of the Minot-Murphy method of therapy was demonstrated by P. McKinlay.[2] Between 1921 and 1927 the standardised death-rate was, he found, to all intents and purposes constant. In 1928 an appreciable fall was recorded for both sexes, and this improvement in the comparatively short space of time succeeding the introduction of liver therapy naturally raised hopes of a still further decline in the death-rate when the treatment was extended to a still larger number of patients.

These hopes have unfortunately not been fulfilled. Since 1928 the rates (standardised for age) have steadily risen again and in 1932 were only approximately 15 per cent. below those registered in the three or four years preceding the new treatment. Comparison of the death-rates age by age shows that in 1928, when the treatment was widely adopted, the mortality was appreciably lower than in 1927 in each decade of life from 25 years onwards. Yet in 1932 the mortality of females in each age-group was more unfavourable than that recorded in 1928, though at ages 25–65 it is still much lower than the mortality in 1927. At ages over 65 years the females in 1932 have even higher death-rates than in 1927, the year in which liver treatment was introduced. Amongst males, the death-rates at each age over 45 are considerably higher in 1932 than in 1928, though only in old age, over 75 years, does the rate exceed that registered in 1927.

The fall in the death-rate that immediately followed liver treatment was very striking. The subsequent lack of improvement, and in most age-groups an actual deterioration, is a problem which demands attention. If, as Dr. L. J. Witts suggests on another page, the prognosis of pernicious anæmia is chiefly determined by the care and skill of the physician and the coöperation of the patient, it should be possible to reduce the death-rate considerably. Probably the most common mistake is under-dosage. It is heartening to note the opinion of one so experienced in the treatment of pernicious anæmia as Dr. Witts that if certain precautions are taken "a patient with pernicious anæmia probably has the same expectation of life and physical well-being as his fellow men."

INFLUENZAL MENINGITIS

SINCE the first authentic case of influenzal meningitis was described by Slawyk[3] in 1899, a considerable number of other workers have studied the disease. T. M. Rivers[4] in 1922 was able to collect records of 220 cases, while F. E. Koch and E. Krämer[5] in 1931 increased this number to 298. The disease must, however, be considerably more common than these figures would suggest. Recently Neal, Jackson, and Appelbaum[6] have reviewed 2727 cases of meningitis which they have seen in the past 23 years, and of these no fewer than 111 were due to the Pfeiffer bacillus. In its clinical and pathological manifestations influenzal meningitis presents a curious uniformity. By far the greater number of cases occur in infancy and early childhood, 60 to 80 per cent. being in children under two years of age. Most often the disease appears to be primary, though preceding or concomitant conditions, such as pneumonia or otitis media, which are by no means necessarily due to Pfeiffer's bacillus, are often observed. The symptomatology closely resembles that of meningococcal meningitis, and one of the most frequent initial symptoms in infants is gastro-intestinal disturbance. The cerebrospinal fluid is under pressure, is cloudy or purulent, has a high cell content, especially of polymorphs, and shows a variable increase in protein and often a marked decrease in sugar. Gram-negative bacilli, with the typical Pfeiffer morphology, sometimes accompanied by long thread forms, are seen microscopically, and can usually be cultivated on suitable media. The same organism can often be isolated from the blood stream, and from the purulent joint exudates which are sometimes observed as a complication of the disease. The organisms produce indol and resemble Pfeiffer bacilli of respiratory origin very closely. They differ from these, however, in their high pathogenicity for laboratory animals. Injected intraperitoneally into rabbits, guinea-pigs, rats, and mice, they frequently give rise to a fatal septicæmia and to purulent effusions in the serous cavities.

The disease is often prolonged, lasting usually 10–20 days, and having a very high mortality-rate—somewhere about 95 per cent. This fact renders all the more interesting the two cases, recorded in our present issue by Dr. S. C. Dyke and Dr. C. J. H. Little, both of which made a perfect recovery. Whether this was connected in any way with the age of the patients, 22 years and 8 years respectively, it is impossible to say. It is noteworthy that the meningeal infection seems to have been relatively mild, for in neither case were the organisms found microscopically in the cerebro-spinal fluid. The treatment of the disease has so far proved disappointing. In the United States the tendency is to perform frequent lumbar punctures and to inoculate anti-influenzal serum both intrathecally and intravenously.

SCIENTIFIC RESEARCH AND SOCIAL NEEDS

AT the suggestion of the B.B.C. Mr. Julian Huxley went on a tour through Britain to see what science was doing for human life; this led to a dozen wireless talks which have now been published in book form.[1] He considers in order the influence of scientific research in our universities and institutes on food, building, clothing, health, communications, war and international relations. The descriptive chapters contain a wealth of interesting though scrappy information about the recent applications of research to industry of various kinds; interspersed among them are four real or imaginary and rather tedious conversations wondering what it all means. The tone and atmosphere of the whole is perhaps best shown by the author's own conclusion as stated in the preface: "I became more and more impressed with the fact that both our existing structure of civilisation and our hope of progress are based on science." What exactly is meant by "science" is not clear; presumably an attitude of mind which prefers to have tolerably sound reasons for its beliefs and, where possible, to test them by experiment. If empirical experience is ruled out, then the word "fact" which Mr. Huxley glibly substitutes for "notion" is quite out of place; our existing civilisation is largely based on the shrewd appreciation by then ancients (and perhaps by our more remote ancestors) of such fundamentals as that fallowing increased the fertility of the soil, that close contact with excreta was objectionable, that cabbage was first-rate food, that human kindness was above rubies. "Science" may have discovered why some of these things are good, but it certainly did not find out that they were good nor is their incorporation into daily life due to its advocacy. What Mr. Huxley probably means is that, especially in recent times, deliberate scientific investigation has enabled many alterations to be made in the surface details of life. With this everyone will agree and almost everyone will be grateful for better food, better houses, better health, and the generally easier and richer existence which has become available. We deprecate, however, his implication that "science" is all that is necessary for salvation; it makes its substantial contribution to our comfort and convenience, but he claims too much for it; good men are useful too.

RESEARCH IN BACTERIAL CHEMISTRY

THE Medical Research Council announce the inauguration of new arrangements for further combined chemical and bacteriological investigations into the conditions which govern the life and multiplication of micro-organisms causing disease. These have been made possible by the generous coöperation of the Middlesex Hospital medical school, the trustees of the late Lord Leverhulme, and the Sir Halley Stewart Trust. Accommodation and facilities are being provided at the Middlesex Hospital in the Bland-Sutton institute of pathology and the adjoining Courtauld institute of biochemistry. The investigations will be directed by Dr. Paul Fildes, F.R.S., who has been appointed a member of the scientific staff of the Medical Research Council. The other workers are Mr. B. C. J. G. Knight, with a Halley Stewart research fellowship, and Dr. G. P. Gladstone and Dr. G. Maxwell Richardson, holding Leverhulme research fellowships. The arrangements took effect on June 1st, and the support given by the coöperating bodies is sufficient for an initial period of five years.

A BEQUEST TO A NON-EXISTENT HOSPITAL

IT is unfortunate that people who mean to leave money to a hospital should, in making their wills, sometimes use such an inexact description of the hospital as to defeat their generous object. A fresh case of this kind came to light last week on a summons before Mr. Justice Bennett. Thomas Stanley Forshaw, who died in 1930, left property (subject to a life interest) unconditionally to "the Middlesex Children's Hospital, Middlesex-street, London, W." What did he mean? There was in Middlesex no "Middlesex Children's Hospital." There was a Middlesex-street in London, but not in "London, W.," and there was no hospital in Middlesex-street. Consequently, as the judge remarked, there was no institution which bore the name or the address to be found in the will as the institution to which Mr. Forshaw gave the property. The Middlesex Hospital in Mortimer-street was able to show that Mr. Forshaw had taken an interest in its work; the evidence, it was suggested, pointed to the conclusion that Mr. Forshaw had the Middlesex Hospital in Mortimer-street in mind when he made the bequest. The judge, however, did not find the evidence conclusive. There remained a legal question to be decided—did the legacy fail and did the property pass to the next of kin as on an intestacy or would the court apply what is known as the *cy-près* doctrine? This mysterious-looking law-French expression means that the court will try to get so near (*si-près*) to the testator's intentions as it can; it will give an approximate interpretation to the language he has used. But courts are not prepared to apply the *cy-près* doctrine unless satisfied that the testator meant to benefit a particular charitable purpose rather than a particular institution. Mr. Justice Bennett declared himself not so satisfied. He found himself without any clue to Mr. Forshaw's intention apart from the words which named "The Middlesex Children's Hospital, Middlesex-street, London, W." As the address of a particular institution was so specifically set out in the bequest, the judge felt obliged to hold that the testator had an institution in mind and not a purpose. In the circumstances, the judge concluded, it was impossible to find the institution. The legacy therefore failed and the property went to the next of kin as if on an intestacy.

THE USE AND ABUSE OF A SALT-FREE DIET

FOR many years the salt-free régime has been used as a therapeutic measure particularly in disorders of the kidney. A series of communications from a score of continental physicians on the indications for and against this treatment appear in a recent issue of *La Vie Médicale.*[1] It is generally accepted that the use of salt-free diets arose from the work of Widal in France and Strauss in Germany. Widal found that in patients with œdematous nephritis salt administration increased and withdrawal of salt decreased the amount of œdema. In many cases this relationship was found to be so definite that variations in the degree of œdema could be produced at will by altering the intake of common salt, and the treatment of œdema by a salt-free diet achieved widespread and deserved popularity. Unfortunately this success in cases of dropsy led to the indiscriminate use of salt-free diets in other disorders. In chronic œdematous nephritis the value of a salt-free diet in reducing œdema is scarcely disputed. Many ambulant cases of chronic nephritis with swollen legs and puffy faces can be kept free from these discomforts merely by restricting the intake of common salt. Often it is enough if no salt is used in the cooking or at table, but sometimes it is also necessary to recommend salt-free butter and bread. In cases of dropsy so severe that the patient is bedridden a salt-free diet usually removes some but not all of the œdema.

Any amelioration of œdema is appreciated by the patient. In a prolonged, trying, and often hopeless illness it provides what appears to be tangible evidence of at least a partial recovery. In mild cases it allows the patient to undertake more bodily activity and in severe cases often relieves the mechanical discomfort due to stretching of the skin and subcutaneous tissues. Moreover, the complications of sepsis in œdematous limbs and of pulmonary œdema occur less frequently if the accumulation of large dropsical effusions is limited by a salt-free diet. While patients are usually more comfortable on a salt-free diet, however, it is doubtful whether this régime produces any durable improvement in their health, and it is therefore important to know whether any disadvantages are attached to its enforcement. In 1928 L. Blum observed in certain cases of nephritis a marked increase in blood-urea, previously normal or but moderately raised, when salt was withdrawn from the diet. It is scarcely surprising, therefore, that many physicians hesitate to recommend this diet to patients who already have a tendency to nitrogen retention in the blood. It seems, however, that, in chronic nephritis with œdema, nitrogen retention rarely in practice gives rise to the symptoms which are usually associated with a failure to excrete the products of nitrogen metabolism. A salt-free diet often causes loss of appetite and, it is said, digestive disturbances. The loss of appetite is in part due to the lack of taste in the food and may recover almost at once when salted food is given. In a few cases there may be a genuine interference with the digestive function. Nervousness, twitching movements of the skeletal muscles, and headache are also said to develop as a result of a salt-free diet. These symptoms do not, however, arise frequently, and when they do occur in nephritis it may well be that they are the results of early uræmia and not of salt deficiency.

---

[1] La Vie Médicale, April 25th, 1934.

A salt-free diet has been recommended in œdema due to causes other than chronic parenchymatous nephritis. Thus in dropsy due to congestive heart failure it appears that a reduction in the intake of salt decreases the rate at which the fluid accumulates and in some cases hastens the removal of œdema and ascites. The use of a salt-free diet in non-œdematous cases of nephritis as a rule is to be condemned, because there is no clear evidence of its value and because the nitrogen retention and the digestive disturbances which may attend its use may cause discomfort if not actual harm to the patient. A possible exception to this rule is in a condition called "chloruræmia," where there is an accumulation of chlorides in the blood. Chloruræmia occurs in non-œdematous cases of nephritis, and in these cases the high plasma chloride upon which the diagnosis depends can be reduced to normal limits by diminishing the intake of salt. Whether anything is to be gained by this procedure is not yet clear. In essential hypertension a salt-poor diet frequently produces a fall in the blood pressure. There seems to be no objection to its use, though the mechanism of this process is unexplained. The treatment of epilepsy by bromides may be reinforced by a salt-free diet, the chloride of the body is replaced by bromide and less of the bromide is excreted. It should be remembered in this connexion that the use of a salt-free diet in combination with bromide is equivalent to increasing the dose of bromide.

THE ORDER OF ST. JOHN

THE occurrence this week of the general assembly of the Order of St. John of Jerusalem reminds us of the close association between the Order and the medical profession, alike through the control of the ophthalmological hospital at Jerusalem and the organisation of the St. John Ambulance Brigade. After the religious service Sir John Duncan and Colonel J. L. Sleeman, respectively chief commissioners of the ambulance brigade and the brigade overseas, gave an account of the work of their departments during the past year. It was reported that nearly half a million calls upon the ambulance department at home had been made, including 17,000 motor accidents. A large number of patients had been carried by the motor ambulances of the brigade which has considerably extended the number of its divisions. The activities of the Order of St. John show that deep respect for medieval forms and formalities can accompany fine modern work for the public good.

A SERUM TEST FOR MALARIA

IN 1928 A. F. X. Henry showed that serum from cases of malaria had the capacity of flocculating melanin pigment, and that this property was apparently specific. This observation of Henry has received considerable support from the results of continental workers, but the form of melanin employed left much to be desired, since it was obtained from the choroid of an ox. Lieut.-Colonel E. D. W Greig, Dr. C. E. van Rooyen, and Mr. E. B. Hendry, working in the bacteriological department of Edinburgh University, have now succeeded in improving the technique of the test, and give a brief description of their method on another page. The melanin used by them is extracted from human hair readily obtained from the barber, and is in a stable colloidal solution, so that it can be put up in ampoules and applied in field tests. Sera from several cases of active and latent malaria respectively were found by the Edinburgh workers to give positive results, while out of 129 sera from non-malarial patients all except two proved negative. The future of this test will be watched with interest, as a trustworthy but relatively simple serum reaction for malaria would prove of great practical utility.

THREE professorial appointments in the British Post-Graduate Medical College, at Hammersmith, are announced in our news columns. Prof. F. R. Fraser and Prof. E. H. Kettle are leaving St. Bartholomew's Hospital to occupy the chairs of medicine and pathology respectively, and Dr. James Young is coming from Edinburgh to be professor of obstetrics and gynæcology.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 16TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 3 (last week 2); scarlet fever, 2483; diphtheria, 1186; enteric fever, 13; acute pneumonia (primary or influenzal), 863; puerperal fever, 35; puerperal pyrexia, 105; cerebro-spinal fever, 20; acute poliomyelitis, 2; acute polio-encephalitis, 1; encephalitis lethargica, 4; *continued fever, 1 (Cambridge)*; dysentery, 5; ophthalmia neonatorum, 70. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 25th–26th was as follows: Small-pox, 5 under treatment, 0 under observation (last week 3 and 0 respectively); scarlet fever, 1571; diphtheria, 1671; measles, 1547 (last week 1750); whooping-cough, 283; puerperal fever, 24 mothers (plus 8 babies); encephalitis lethargica, 268; poliomyelitis, 2; "other diseases," 219. At St. Margaret's Hospital there were 19 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 35 (11) from measles, 8 (2) from scarlet fever, 22 (7) from whooping-cough, 43 (11) from diphtheria, 43 (7) from diarrhœa and enteritis under two years, and 35 (4) from influenza. The figures in parentheses are those for London itself.

Bradford reported the only death from enteric fever. Liverpool reported 4 fatal cases of measles, Rochdale 3, no other great town more than 2. Four persons died of diphtheria at Liverpool, 3 at Bradford and at Leeds.

The number of stillbirths notified during the week was 251 (corresponding to a rate of 37 per 1000 total births), including 39 in London.

LONDON SCHOOL OF MEDICINE FOR WOMEN.—Prof. L. N. G. Filon, F.R.S., vice-chancellor of the University of London, will present the prizes of this school in the Albert Levy hall of the Royal Free Hospital at 3.30 P.M. on Wednesday, July 11th.

LONDON HOSPITAL MEDICAL COLLEGE.—On Tuesday next, July 3rd, the Queen is opening the new students' hostel attached to the London Hospital. A week later, on July 10th, Mr. Walter Elliot, M.P., the Minister of Agriculture, will distribute prizes in the medical college.

PROGNOSIS

A Series of Signed Articles contributed by invitation

VIII.—PROGNOSIS OF PERNICIOUS ANÆMIA

THE prognosis of pernicious anæmia is chiefly determined by the care and skill of the physician and the coöperation of the patient. The treatment of the disease is simple, but the penalty of inadequate treatment is severe. It is little advantage to a patient to be relieved of his anæmia only to develop paralysis later, but this has been the fate of many during the last ten years. Avoidance of this disaster does not require any special skill, but it does entail strict adherence to the rule that sufficient effective substance must be given to maintain the blood count constantly at a normal level. Intelligent patients often learn to estimate their own hæmoglobin and look after themselves efficiently. The majority need to remain under medical supervision, so that their hæmoglobin can be tested at least once every six weeks, and so that the onset of symptoms suggestive of subacute combined degeneration, such as paræsthesiæ or rheumatic pains in the limbs, can at once be countered by massive dosage of effective substance. If these precautions are taken, a patient with pernicious anæmia probably has the same expectation of life and physical well-being as his fellow men.

The immediate prognosis of pernicious anæmia is dependent on the severity of the anæmia and the presence of nervous or other complications. When the red cell count is below one million, the hold on life is always precarious and death may occur from syncope or from a trivial infection. Patients in this condition are to be regarded as medical urgencies, which demand prompt and vigorous treatment. The only treatment to be considered is the parenteral administration of liver extract, with or without transfusion of a pint of blood. The more experienced the physician, the less recourse will he have to transfusion, which is not free from risk in these collapsed patients. The ideal treatment in emergencies is probably the slow intravenous injection of 5 c.cm. of a reliable intravenous preparation of liver, followed by the daily intramuscular injection of 6 c.cm. of one of the intramuscular extracts. The intravenous injection should be given very slowly, preferably in about 20 c.cm. of warm normal saline solution. When the count is above one million red blood-cells per c.mm., transfusion and intravenous injections should be avoided and treatment confined to the injection of 2 to 4 c.cm. of an intramuscular extract daily. Improvement is usually visible in 24 to 48 hours and the patient should be out of danger of death from anæmia by the end of a week. Diminished resistance to infections, especially those of streptococcal origin, appears to persist until the red cells rise above three million per c.mm. Intensive treatment should therefore be continued until this level is reached, and the patient carefully sheltered from the risk of infection.

When the anæmia is complicated by infection, the outlook is grave and a guarded prognosis must be given. The blood picture is often atypical in certain features, and the response to the anti-anæmic principle may be inhibited by the infection. In these circumstances transfusion may become the treatment of choice. However ill the patient may be, hope of recovery should not be too soon abandoned; I have reported the case of a man in a relapse of pernicious anæmia who contracted staphylococcal septicæmia and recovered after a very severe illness in which six transfusions were given.

SUBACUTE COMBINED DEGENERATION

In an unfortunately high percentage of cases, especially those who have relapsed through omission of treatment after previous repair of the anæmia, the presenting symptom is not anæmia but subacute combined degeneration of the spinal cord. It is not my intention to minimise the gravity of this complication and it is obvious that nervous tissue which has been killed cannot be replaced. Nevertheless I do feel that the prognosis of subacute combined degeneration is often painted in too gloomy colours. All of us are familiar with the remarkable improvement which may occur after an attack of transverse myelitis or during a remission of disseminated sclerosis. The same improvement is possible in subacute combined degeneration. The stages of the lesion are, usually, subjective sensory involvement; objective sensory involvement with Rombergism and loss of vibration sense; ataxic paraplegia; and complete flaccid paralysis, usually complicated by infection of the urinary tract. Paræsthesia, like the lightning pains of tabes dorsalis, may be a troublesome symptom to overcome, persisting after the objective signs of spinal degeneration have disappeared; apart from this, sensory changes are relatively benign and complete recovery may occur, with the return of vibration sense and tactile sensibility. Spastic changes are more serious, but many completely paralysed patients have learnt to walk again, and in rare instances an extensor Babinski reflex may become flexor. Complete flaccid paralysis is usually a terminal event, and if the urine is also infected or bedsores are present, the very gravest prognosis should be given. The treatment of these spinal lesions is intensive parenteral liver therapy, with massage, re-education, and encouragement; large doses of iron may also be employed.

OTHER COMPLICATIONS

Apart from irreparable nervous changes, complete recovery should be made from an attack of pernicious anæmia, the hæmoglobin rising to 100 per cent. or higher and the patient feeling perfectly fit. If this happy consummation is not attained, search should be made for a complication. Of these the most important are iron deficiency, hypothyroidism, sepsis, and arterio-sclerosis.

Iron deficiency is probably more common in pernicious anæmia than we have hitherto appreciated. When regeneration of the blood takes place, the iron stores of the organism are soon depleted and may prove insufficient for complete repair of the anæmia. I have gradually swung over to the view that iron should always be given in pernicious anæmia in full doses by mouth until the hæmoglobin is normal, when it can be omitted.

Myxœdema, while not common, at times coexists with pernicious anæmia, and in such cases thyroid extract is necessary to restore the patient to complete health.

Focal sepsis is not given the same importance in the ætiology of pernicious anæmia as it was ten years ago, but there is no doubt that a septic focus may inhibit the response to liver treatment, and such a focus should be sought for in refractory patients. Refractoriness in other cases has been attributed to *arterio-sclerosis* and to disease of the liver. Some patients are certainly refractory, even though liver extract is administered parenterally. If the diagnosis of pernicious anæmia seems unquestionable, the indication is to give massive dosage of liver; C. R. Rhoads has described a patient who did not improve until 20 c.cm. of liver extract were injected daily by the intravenous route.

MAINTENANCE TREATMENT

With these reservations and qualifications, it should be possible to restore every patient with pernicious anæmia to complete health, and health should then be maintained indefinitely. The onset of subacute combined degeneration is always preventable if adequate treatment is given, as J. F. Wilkinson has so clearly shown in his large pernicious anæmia clinic in Manchester. Maintenance treatment with 1 oz. of desiccated stomach daily, or with the intramuscular injection of 2 c.cm. of liver at weekly or fortnightly intervals is now so cheap that failure to remain well is a reflection on the common sense of the patient or his adviser. Fear is sometimes expressed that the bone-marrow in pernicious anæmia may become aplastic and the patient may finally reach a stage in which he no longer reacts to liver therapy. This fear is groundless, for complete aplasia of the bone-marrow rarely if ever occurs in pernicious anæmia.

Sufferers from pernicious anæmia must ultimately die, even though they are cured of their anæmia, and evidence has been produced which suggests that they are more than ordinarily liable to succumb to carcinoma of the stomach. A. F. Hurst and others maintain that the achylia, which is the basic lesion of pernicious anæmia, is the result of gastritis from chronic irritation of the stomach, and they believe that this gastritis is sometimes a precancerous change, which terminates in a definite neoplasm of the stomach. The evidence for this theory is certainly suggestive, but not yet statistically convincing. After all, both achlorhydria and carcinoma of the stomach are common in the later decades of life, and we shall need to wait some years before we are persuaded that carcinoma of the stomach is commoner in patients treated for pernicious anæmia than in other men and women of the same age. It is wise for the physician to bear the possibility in mind and to attach special importance to the occurrence or recurrence of dyspepsia in a patient treated for pernicious anæmia. It would be wrong, however, to let the fear of malignant disease overshadow the success of the liver treatment, and at present I feel that the rather heroic programme of gastric lavage, suggested by Hurst to prevent the onset of carcinoma of the stomach in pernicious anæmia, is hardly justified.

SUBSTITUTION

Although I have spoken of the cure of pernicious anæmia, the treatment is essentially a substitution therapy, and the disease recurs when treatment is *omitted. In very rare instances complete cure* has taken place, the gastric secretion has returned to normal, and the patient has remained well without need for further treatment. This is so rare an event that it may for all practical purposes be disregarded in prognosis. Hurst has suggested that complete recovery of this type would be more frequent if septic foci were always removed from the mouth and throat, the stomach washed out as a routine, the diet kept bland, and the digestion aided by the prescription of hydrochloric acid. Most observers, however, are of the opinion that by the time pernicious anæmia develops the damage inflicted on the gastric mucous membrane is so extreme that there is little or no chance of its recovering the power of secreting the ferments which normally maintain the blood in a healthy state. Complete cure of pernicious anæmia will probably remain as rare as the complete cure of diabetes mellitus or myxœdema. To maintain health treatment must be continued indefinitely and with the utmost regularity.

L. J. WITTS, M.D., F.R.C.P.,
Assistant Physician, Guy's Hospital.

SPECIAL ARTICLES

LISTER INSTITUTE OF PREVENTIVE MEDICINE

(Concluded from p. 1310)

Work on Nutrition

DURING the last three years workers on *vitamin problems* in this Institute have devoted much time and attention to points connected with the standard adopted at the first meeting of the International Conference on Vitamin Standards and Units held in 1931. The subjects investigated have included the following:

Vitamin A: pure *crystalline carotene* as standard; influence on stability of temperature and of solvent used; the relative value of various methods of vitamin A estimation (Miss E. M. Hume and co-workers).

Vitamin B_1 (antineuritic): stability at different temperatures of the standard absorption product on acid fullers' earth from rice polishings (Miss H. Chick, D.Sc., Miss H. M. Jackson, and Mr. G. Prunty).

Vitamin C: suitability of pure ascorbic acid as standard *in place* of the fresh lemon juice previously recommended (Mr. S. S. Zilva, D.Sc., and co-workers). At the request of the Accessory Food Factors (Vitamins) Committee, the potency of ascorbic acid has been evaluated. The results obtained show that the activity of 1 mg. of ascorbic acid is equivalent to 20–30 international units (2–3 c.cm. of lemon juice).

Carotene as source of vitamin A.—Miss Hume and Miss H. Henderson Smith, in coöperation with Mrs. I. Smedley-MacLean, D.Sc., conclude, after testing specimens of coconut oil, which is used as a solvent for crystalline carotene, that the same sample of carotene dissolved in different samples of coconut oil does not always have the same biological value.

Recent researches have established the existence of many isomeric forms of carotene and of certain derivatives, all of which possess biological activity, the essential common factor being apparently the presence of an intact β-ionone ring with four conjugated double bonds attached. β-carotene differs from the other active *carotenes in having two such rings and in showing at least* twice their biological activity. It is necessary to establish more accurately the relative activity of β-carotene and that of the sample of carotene used as international standard, and also to ascertain the exact quantitative relation between the biological activity of pure β-carotene and the purest sample of vitamin A obtainable.

Effect of vitamin A deficiency on the eye.—Mrs. K. *Tansley Lythgoe, Ph.D. (Medical* Research Council grantee), has investigated the effect of vitamin-A deficiency on the development of the retina and of visual purple in young rats.

Mrs. Lythgoe's previous work had shown a delay in regeneration of visual purple to be one effect of vitamin A deficiency and the probable cause of the night blindness, characteristic of this dietary effect. The present work, still incomplete, indicates that defects in the structure of the retina and definite retardation of the first appearance of visual purple occur in suckling rats when the mother is suffering from a partial vitamin A deficiency. Evidence has also been obtained that administration of cod liver oil to young animals which have been deprived of vitamin A, restores the staining properties of the retina, but cannot repair any structural damage which may have occurred.

Vitamin D: origin and distribution in nature.—Miss A. M. Copping has continued her work on the origin of vitamin D in the ocean.

Further investigation of copepod material has shown that the dried material contained much more than 0·25 international units of vitamin D per gramme. This result would seem to afford a partial, if not complete, explanation of the rich depôts of vitamin D in the liver of the cod fish, which is said to feed largely on copepods at certain seasons of the year.

Evidence has been obtained that the vitamin D, which is abundantly formed when fresh green leaves are exposed to a powerful ultra-violet irradiation, tends to disappear when the material is kept, the rate of disappearance depending on the temperature.

Biological value of proteins.—Dr. Chick and Mr. J. C. D. Hutchinson have been studying the balance sheet method of studying the nutritive value of proteins.

In this method comparison is made of the relative values of proteins to maintain nitrogenous equilibrium in the adult rat. The special points of the study have been: the time required for "wash out" of residual nitrogen, when changing from high to low protein diets and vice versa; the influence of the level (proportion of total calories) at which the protein is present in the diet, the effect of heat and other agencies on the nutritive value of the protein. Most of the work has been done on caseinogen.

Pellagra.—The same workers have done experiments which provide another argument against the theory which would explain the association of endemic pellagra with the use of diets containing maize products as the staple cereal by an amino-acid deficiency in such diets. Dr. Chick and her collaborators have also examined the theory held by some authorities, that the occurrence of pellagra on diets composed largely of maize may be explained by a toxic substance contained in this cereal. Rats and mice have been reared on diets in which 90 per cent. of the calories was derived from maize products, without occurrence of any toxic symptom; nor were any deleterious effects noticed when the animals consuming these diets were exposed to ultra-violet or visible light from artificial sources.

BIOCHEMICAL INVESTIGATIONS

Calcification.—The mechanism of calcification in animal tissues has been further studied by Prof. R. Robison, F.R.S., and Dr. A. H. Rosenheim.

It has been shown that the second calcifying mechanism of hypertrophic cartilage is strongly inhibited by iodoacetate and by fluoride in very low concentrations. This suggests that the second mechanism, like the phosphatase, is enzymic in nature and that the two calcifying mechanisms may together form a complex enzyme system analogous to those of muscle and yeast.

In experiments with other tissues calcification was repeatedly obtained in aortæ of both rats and rabbits by prolonged immersion in highly supersaturated inorganic solutions. The deposits of calcium salts bore some resemblance to those described as occurring in these tissues in experimental hypervitaminosis D.

The oxytocic hormone of the posterior lobe of the pituitary gland.—The study of the chemical nature of the hormone has been actively pursued by Mr. J. M. Gulland, D.Sc., and his collaborators.

With Mr. T. F. Macrae he has begun experiments to identify the inactivating enzymes present in yeast and in trypsin preparations. They defined the criteria by which may be established the identity of a known enzyme which is suspected of inactivating the hormone. As a result of these researches it is apparent that the hormone is not proteinoid, as has been held hitherto by other investigators, but that, if it is peptide in character, its molecular weight is relatively small.

THERAPEUTIC SERA

Gas-gangrene antitoxin (B. welchii).—Within recent years an increasing interest has been taken in the serum treatment of acute peritonitis, intestinal obstruction and gangrenous appendicitis. The theory that has been formed attributes the characteristic toxæmia in these conditions to the action of the toxin of *B. welchii* and this view is supported by encouraging results that have followed the use of a specific antitoxin in this country. There are technical difficulties which complicate the methods of production of the serum. A fresh attempt has been made to simplify the preparation of the toxin and the antitoxin, and the results have been so consistently satisfactory that the methods can now be regarded as purely routine.

Serum for the treatment of poliomyelitis.—Coöperation with the Medical Research Council and the Public Health Department of the London County Council in the preparation and issue of a "convalescent" human serum for the treatment of poliomyelitis is being continued. The serum, when it has passed the necessary tests, is sent to the Western Fever Hospital, London, where early cases of the disease are admitted, and whence it is distributed for use in the treatment of patients who are in the preparalytic stage of the disease.

A new supply of serum from immunised horses has been obtained and found to possess very high virus-neutralising value in tests on monkeys. It is available for prophylactic use in contacts.

THE ECONOMICS OF MEDICAL PRACTICE IN CANADA

(BY A SPECIAL CORRESPONDENT)

THE medical profession in Canada is now grappling with some difficult problems, which have been intensified but by no means created by the economic depression. The conditions under which medical practice is carried on present features that have long been regarded by the profession as highly unsatisfactory, a view which for other reasons is shared by a large section of the general public, and the dissatisfaction has now reached a point at which even many who are ordinarily opposed to change are convinced that things cannot be suffered to remain as they are. The problems of medical service in Canada are in fact not unlike those in the United States, which have been described with great fullness of detail in the publications of the Committee on the Costs of Medical Care,[1] and they are ably summarised in an interesting paper read by Dr. Grant Fleming, professor of public health and preventive medicine in the McGill University, Montreal, at a joint meeting of the College of Physicians of Philadelphia and the American Academy of Political and Social Science held at Philadelphia on Feb. 7th last.

---

[1] See THE LANCET, 1933, ii., 614, 667, 722.

CARE OF "INDIGENTS"

Perhaps the most urgent problem that now presses for solution is that of the medical care of the "indigents"—the transatlantic term for the destitute. Under the British North America Act the responsibility for providing medical care for the indigents devolves upon the respective provinces, but although some provision has been made it usually takes the form of a grant to hospitals on a per caput per diem basis for hospital maintenance, no fees for medical service being included. In Ontario the municipalities are legally required to appoint medical practitioners to treat patients who are "unable, through poverty, to pay for the necessary attendance, and who are not cared for in a public or private hospital." But, according to Prof. Fleming, many municipalities have not fulfilled this obligation, and the medical treatment of the indigent is left to the local doctors. He tells us that "the responsible authorities and the public in Canada have come to take it as accepted fact that the medical profession will give their services, without charge, for the medical care of the indigents."

As the depression deepened so the burden on the doctors increased, and their feeling that they were being unfairly dealt with became acute when the Dominion Government, deciding at last to give financial assistance to the provinces for the relief of the unemployed, announced that the assistance would be limited to a contribution towards the cost of food, shelter, and clothing. The Canadian Medical Association, in an interview with the Prime Minister of the Dominion, submitted strong reasons for their view that the federal contribution should include provision for medical care, but Mr. Bennett, though he agreed that the doctors should be paid for their services, said that payment should be made by the provinces and not by the federal Government. The provincial Governments, however, with the exception of Ontario, have declined to act without a contribution from the Dominion. The Government of Ontario undertake to pay two-thirds of the medical care of persons on unemployment relief if the local municipality pay the remaining third, and the doctors in the province have agreed to accept one-half of their usual fees. Where this scheme has been adopted it has worked well, but many of the municipalities have refused to adopt it, and much unpaid work is still done by the medical profession.

DEMAND FOR ORGANISATION

There are signs that the unfairness of the position in which the doctors are placed is becoming better appreciated by the public, who in many places have viewed with approval the efforts of the profession to secure payment for the medical care of the unemployed. But there are signs also of a growing feeling that the ordinary methods of obtaining medical care by private individual arrangements on a fee for service basis are unsuited to modern conditions. The cost of medical care in Canada as in other countries has steadily increased with the advance of medical science and the growing complexity of medical treatment, and the great majority of the population are unable out of their own unaided resources to afford adequate remuneration for medical services, at all events in a severe or prolonged illness. The public is feeling its way towards some system of paying for medical care by a pooling of individual resources.

One of the most remarkable of such systems is that adopted by the province of Saskatchewan by an Act passed in 1930, which enables a rural municipal council to frame a "by-law empowering the council to engage the services of a legally qualified medical practitioner for the municipality, at a salary not to exceed five thousand dollars per annum, and to submit the same to the electors for their approval." By June, 1933, full-time doctors had been appointed by 37 municipalities, part-time doctors by 30, and 9 municipalities had adopted the by-law but had not yet made an appointment. The Saskatchewan system, which is not limited in its operation to the care of the indigent, has spread to other provinces; municipal doctors have been appointed by five rural municipalities in Manitoba and by three in Alberta. The system appears to have worked satisfactorily on the whole, although the doctors would prefer that the conditions of medical appointments should be controlled by the provincial Governments; at all events the system has not been discontinued in any place in which it has been adopted. Free treatment for tuberculosis is available throughout Saskatchewan, and in 1920 the provincial Government began to give grants to expectant mothers. In 1931 the number of mothers receiving grants was 3020, and the total sum distributed among them was $64,116, of which $26,465 was expended on medical services, which were rendered by 1766 doctors. Unfortunately the maternity grants were discontinued in 1932 for reasons of economy.

COMPULSORY HEALTH INSURANCE

During the last few years the subject of compulsory health insurance has been much discussed in Canada, and special attention has been devoted to the British health insurance system, not with the object of finding out all that can be said against it—an attitude too frequently met with in medical circles in the United States—but from a genuine desire to profit by the experience gained by the 22 years of its operation. The first provincial Government to take up the study of the subject was that of British Columbia, which in 1929 appointed a Royal Commission on State health insurance and maternity benefits. The British Columbia Medical Association, in giving evidence before the Commission, advocated a system of compulsory health insurance which should provide a complete medical service, in which all qualified medical practitioners should have the right to participate, with free choice of doctor and payment per attendance. The Commission recommended the early establishment of compulsory health insurance in British Columbia, and the Government formed after the recent general election is pledged to introduce legislation giving effect to the Commission's recommendations.

The province of Alberta has also appointed a commission to study health insurance, and last year the commission issued an interim report stating that in their opinion: "Adequate medical services for all the people of Alberta can only be secured through the operation of a contributory health insurance scheme." The College of Physicians and Surgeons of Alberta, in laying their views before the commission, said that there was a wide divergence on the subject among the medical profession in Alberta, but added that "in our opinion a considerable majority of the profession in this province would welcome a scheme of State health insurance which would include certain important provisions"—the provisions being similar those formulated by the British Columbia Medical sociation. The Government of Alberta have nounced their intention of introducing a scheme of alth insurance during the present year at a cost of 3 per insured person.

In Manitoba and Quebec the question has also been idied by representative bodies of the medical ofession. In 1930 the College of Physicians and rgeons in Manitoba and the Manitoba Medical sociation appointed a joint committee to study ate medical services and their findings are similar those formulated in the British Medical Association's heme for a general medical service for the nation. Quebec compulsory health insurance has supporters the profession, but there seems to be a feeling that a scheme is introduced it should conform to the rench system, in which the doctor is paid direct r the patient.

The Canadian Medical Association have instructed eir committee on economics "to prepare a plan plans for health insurance to be passed to the arious provincial associations for their consideration, iticism, and suggestions." The object of the ssociation is to ascertain the considered views of the hole profession as a basis for action in any ontingency that may arise.

A CHANGE COMING

In Canada the profession, it seems, is approaching he subject of health insurance with an open mind, nd with a desire to learn what has been done in other ountries, and to profit by the experience of those ountries so far as it can be applied to Canadian onditions. The discriminating approval given to he British scheme by the British Medical Association as naturally had a considerable effect upon instructed pinion in Canada. Prof. Fleming believes that the vast majority of Canadian doctors now think "that a change is coming and that a not inconsiderable percentage want a change." He believes also that "the public are going to insist upon having medical care arranged for on some basis whereby they can pay for it without being unduly burdened."

It is to be hoped that Prof. Fleming will expand his paper and publish it in a form in which it will be readily available. The problems of medical service are pressing in many countries, and it will be a real help to all students of the question to know what Canada is thinking and doing to ensure that her people shall be provided with the medical care they need.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

EDINBURGH FOOT CLINIC

Lord Elphinstone, the new president, at the recent annual general meeting of this clinic declared open the newly completed theatre. The total number of treatments at the clinic during 1933 amounted to 13,633 against 10,362 in the previous year, patients coming from all parts of Scotland. Mr. Robert Stirling, in moving the adoption of the report, referred to the rough-and-ready chiropody practised during the late war when the rule was "burst the blisters and cut off the knobs" and every callosity which offended the æsthetic sense or caused discomfort was ruthlessly attacked with a razor. In the civil population, he said, they had people of all ages who threw undue stress upon their feet, ranging from the youngster who was starting work for the first time and who had to spend long periods standing, to those of sedentary occupation whose developed weight threw a great strain on the arches of the foot. It was, he said, admitted that the highest efficiency in any profession was to be found in the training centre, the best practice being carried out under the shadow of the academic walls. Attached to the foot clinic there was a school of chiropody with a two years' course of training, at the end of which students who satisfied the examiners were awarded the diploma of the Incorporated Society of Chiropodists. The school, he said, had a reputation second to none in the country, and the clinic had always worked in harmony with the medical profession. Lord Elphinstone said that to judge by the rapid development of the last ten years, it seemed inevitable that the clinic would soon require to be open every day and all day to cope with the work.

WELFARE OF THE BLIND

Under the new Act blind persons are entitled to the old age pension at 50 years of age, and local authorities have power to frame welfare schemes. The majority of them have in fact done so, and thanks to the vigorous administration of the Department of Health the care of the blind is one of the best organised services in Scotland. This year the Scottish National Federation for the Welfare of the Blind has met in Aberdeen, with representatives from some 200 centres. The Federation, which has a first-class home-teaching agency, might well take some definite steps to deal with prevention. The time is overdue for such a policy. The State is interested in prevention, since it cannot afford to lose the potential productivity of any of its citizens. Local authorities are interested because they have accepted the principle of increased aliment to the blind. Education authorities are interested, because of the heavy charge on them for the education and training of blind children. Industrial workshops and other organisations for the blind are finding their task increasingly difficult to provide work for their trainees. And the blind themselves, however successful in minimising the sense of handicap or disability, are insistent that their numbers should not be added to. A national committee with intent to reduce the causes of blindness should include officers of the federation, with representatives of government departments, local authorities, education authorities, the Association of medical officers of health, and ophthalmic societies. It might work along with the English committee or independently. Mr. Anderson, the representative of Edinburgh, was in favour of a Scottish preservation of sight committee. Dr. George Mackay, who is a member of the advisory committee appointed by the Department of Health under the recent Act, has prepared a pamphlet on the care of the eye, of which 20,000 copies have been circulated. The federation itself has brought out an illustrated leaflet in an edition of 14,000 copies. Hard words were said at the meeting about the practice of hawking cheap spectacles.

DENTAL DISEASE IN GLASGOW

At the forty-ninth annual meeting of the Incorporated Glasgow Dental Hospital Dr. J. Forbes Webster, dean of the hospital, said that Glasgow was the worst city in Britain for bad teeth. Dental caries was general among young people of 14 years and upwards. The dental profession had spent money in propaganda to educate the public, and had set aside a percentage of their funds for that purpose, but little progress would be made until the problem had been tackled from the time a baby was born. Volume for volume, the saliva in a dirty mouth contained more disease germs than ordinary sewage; that was why a man was fined 40s. if he spat in a corporation tramcar. During the past year 45,383 teeth were extracted at the hospital, but only 8235 —one out of every seven or eight—were preserved by conservation work. If only the cases came into their hands earlier the proportion of teeth saved could be greatly increased.

EXHAUSTION AND MENTAL DISORDER

In his annual report of Glengall Hospital, Ayr County, Dr. Douglas McRae states that 60 per cent. of the cases admitted during the year were found *in a seriously exhausted condition requiring anxious* nursing attention. This figure, which is the same as last year's, is in striking contrast with the 25 per cent. rate that prevailed before the war. Another unsatisfactory feature is the fact that, in 60 per cent. of the men and 50 per cent. of the women, the mental illness had been established for over a year before the patient was sent into hospital; the corresponding figures for the last pre-war year (1913) were 40 and 27. A study of the types of mental affection in the cases admitted during the year gives a curability of 33 per cent. (men 30, women 36), just half the number of possible recoveries among the admissions of 1909–1913. *Either there is twice as much incurable insanity* in the general community to-day compared with 25 years ago, or the delay in sending cases until a hopeless chronicity is established has doubled. Alcoholic excess was evident in 12 per cent. of the men and 4 per cent. of the women as compared with 51 and 10 in 1913. One gathers from the report that methods of treatment of early cases are well in advance of public opinion and possibly of private practice generally.

IRELAND

(FROM OUR OWN CORRESPONDENT)

A CENTRAL FEVER HOSPITAL

A LETTER from the Hospitals Commission to the Dublin county council announces an important decision. The Commission has been examining the facilities for the treatment of fevers in Dublin, and has arrived at conclusions which it proposes to embody in a recommendation to the Minister for Local Government and Public Health. A scheme is to be put forward for the concentration of the treatment of fevers in a central fever hospital, controlled by a board of management. This will be representative of the public bodies on whom lies the statutory duty of providing adequate treatment of fevers, and also of the board of Cork Street Fever Hospital which has hitherto been the principal agency in Dublin by which that duty has been discharged. It is suggested that the board of management should consist of seventeen members—seven to be appointed by the corporation of Dublin, three by the County Dublin County Council, and seven by the board of Cork Street Hospital. The Commission also proposes to invite the principal medical bodies to associate themselves in an advisory capacity with the board of management. A measure of agreement has been reached with the authorities of Cork Street Hospital by which they will contribute from their assets towards the upkeep of the new hospital.

The proposals of the Commission, if carried into effect, will cause a great improvement in the treatment of fevers in Dublin. The Cork Street accommodation has long been inadequate, and many of the buildings are unsuitable. Its work was supplemented by "fever wings" at several of the general hospitals, a system which was very convenient for clinical teaching, but did not tend to limit the spread of infection. Dublin may now look forward to a really modern fever hospital adequate to its needs.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

PREOCCUPATIONS OF PUBLIC HEALTH OFFICERS

EVERY year the health commissioners of the various States meet with the provincial health officers of Canada and the officers of the U.S. Public Health Service in Washington. The conference held this year from June 4th to 8th constituted the thirty-second annual conference with the U.S. Public Health Service and the forty-ninth annual conference of the State and Provincial Health Authorities of North America.

Much attention was given to the nation-wide epidemic of amœbic dysentery, which originated (as described in THE LANCET of January 6th and April 7th) in Chicago during the World Fair. Dr. Herman N. Bundesen reported the measures taken to deal with the outbreak, and other speakers gave an account of the defective plumbing in the hotel whence infection spread. In the basement of this building were found cross-connexions between the condenser water-pipes of the CO_2 ice machines and the sewers; and there were also two leaks in the sewer-pipes from which sewage dripped directly into an open ice-water tank! The question arose why there had been no epidemic of typhoid fever under these conditions. The only plausible explanation is that the amount of residual chlorine in the city water supply was sufficient to destroy *Bacillus typhosus* but not the more resistant *Entamœba histolytica*.

The conference went on to record in favour of universal pasteurisation of milk in the following resolution carried *nem. con.*: "The conference recommends to the American people that all milk intended for *human consumption should be pasteurised.*"

The conference with the U.S.P.H.S. was welcomed personally by the Secretary of the Treasury (Hon. H. Morgenthau, Jr.) and was presided over by the Surgeon-General, Dr. Hugh S. Cumming, who described most profitably to the delegates his recent visit to England, and his investigation of the present administration of national health insurance in this country. Assistant-Surgeon-General C. E. Waller opened a discussion on the sanitary improvements that have been effected in various States through projects designed to relieve unemployment and subsidised by the federal government. In some of the southern States extensive and highly important drainage projects for the control of malaria have been carried through. Both there and elsewhere thousands of sanitary privies have been built, local funds supplying material, while the labour was paid from federal subsidy. These civil works projects, as they are called, have not, however, been everywhere equally successful. Sudden withdrawal of federal aid has left some communities with large stocks of material and no labour to make use of it. In other States projects have been undertaken independently of the State health department with unfortunate lack of skilled direction. Elsewhere again the State relief administration has proved less coöperative and sanitary projects have not been approved for subsidy. In general it was felt that in an emergency administration handling such vast sums of money and spending them so rapidly some defects in organisation were inevitable.

A discussion of the two types of small-pox was opened by a paper given by A. W. Hedrick, D.Sc., Johns Hopkins School of Hygiene. Dr. Hedrick recommended the separate notification of variola major and variola minor, but this recommendation was not very favourably received. It was felt that the distinction could not always be made; that classifying variola minor as a disease of secondary importance would lead to neglect in reporting it; that the assumption that only two strains of variola are in circulation is not yet justified.

THE SERVICES

INDIAN MEDICAL SERVICE ANNUAL DINNER

Sir Leonard Rogers presided at the annual dinner of the Indian Medical Service held at the Trocadero on June 20th, when there was a record attendance of 105 officers. There were present as guests, Mr. S. K. Browne, C.B., C.V.O., Mr. F. H. Brown, C.I.E. (*Times* Correspondent for India and the East), Dr. N. G. Horner (*British Medical Journal*), and Dr. Egbert Morland (*The Lancet*). Six officers on probation—Capt. A. A. Pullar, Lt. R. D. de Soldenhoff, Lt. R. L. H. Minchin, Lt. R. R. Prosser, Lt. T. K. White, and Lt. E. Parry—attended by invitation. The other members of the Service present were as follows:

Major-Generals: Sir John Megaw, K.C.I.E., H. R. Nutt, V.H.S., G. Tate, C I.E.

Colonels: H. Ainsworth, J. Anderson, C.I.E., R. F. Baird, Sir Samuel Christophers, C.I.E., O.B.E., F.R.S., J. K. Close, J. Crimmin, V.C., C.B., C.I.E., P. Dee, A. B. Fry, C.B., C.I.E., D.S.O., J. Fuller-Good, T. A. Grainger, C.M.G., C. R. M. Green, W. H. Leonard, C.B., K.H.P., F. P. Mackie, C.S.I., O.B.E., A. J. Macnab, C.B., C.M.G., J. McPherson, C.I.E., Sir Richard Needham, C.I.E., D.S.O., J. J. Pratt, Ashton Street, R. G. Turner, C.M.G., D.S.O., W. S. Willmore, C. N. C. Wimberley, C.M.G.

Lieut.-Colonels: W. G. P. Alpin, O.B.E., C. H. Barber, D.S.O., F. A. Barker, O.B.E., A. Buchanan, R. H. Candy, H. P. Cook, H. S. Cormack, M.C., D. Coutts, D. G. Crawford, J. M. Crawford, O.B.E., J. B. Dalzell Hunter, O.B.E., C. D. Dawes, C. Duer, H. R. Dutton, C.I.E., S. C. Evans, J. K. S. Fleming, C.B.E., C. A. Godson, M.C., G. F. Graham, V. B. Green-Armytage, A. F. Hamilton, C.I.E., J. B. Hanafin, C.I.E., H. Hingston, J. M. Holmes, E. V. Hugo, C.M.G., M. L. C. Irvine, S. P. James, I. Davenport Jones, H. C. Keates, H. Kirkpatrick, W. B. Lane, C.I.E., C.B.E., J. C. H. Leicester, C.I.E., I. M. Macrae, C.I.E., O.B.E., A. A. McNeight, E. C. G. Maddock, C.I.E., F. O. N. Mell, C.I.E., T. R. Mulroney, C. Newcomb, B. E. M. Newland, F. O'Kinealy, C.I.E., C.V.O., E. J. O'Meara, O.B.E., M. A. Rahman, H. Ross, C.I.E., D.S.O., W. S. J. Shaw, F. B. Shettle, O.B.E., G. M. C. Smith, C.M.G., W. C. Spackman, H. B. Steen, T. G. N. Stokes, H. Stott, O.B.E., J. Taylor, D.S.O., C. Thomson, E. O. Thurston, R. S. Townsend, M.C., A. G. Tressider, C.I.E., E. L. Ward, C.B.E., T. C. McCombie Young.

Majors: P. M. Antia, J. G. Bird, A. N. Bose, M.B.E., H. C. Brown, C.I.E., J. C. Chukerbuti, W. H. Crichton, J. A. Cruickshank, M.C., J. L. Donnelly, Sir T. Carey Evans, M.C., J. S. Galvin, N. H. Hume, G. R. McRobert, D. V. O'Malley, O.B.E., C. J. L. Patch, M.C., C. G. Seymour, E. A. C. Smith, H. Williamson, O.B.E.

Captains: D. C. Chopra, A. M. Fraser, R. T. Hicks, T. A. Malone, J. S. McMillan, Assa Singh, R. A. Wesson.

After giving the toast of The King-Emperor, the Chairman recalled the improvement in conditions of service in India during his lifetime, and his own efforts in the last five years as medical adviser to the India Office.

Sir Leonard Rogers said that to those like himself who entered the I.M.S. 40 years ago, pessimism about the future of the service might appear justified in so far as there were fewer opportunities for the favoured few in presidency towns to make small fortunes. But from the point of view of presenting favourable opportunities for good professional service he thought a much more optimistic view might be held. In some ways the conditions had improved: for example, on the military side, by the provision under the station hospital system of better conditions of work with increased responsibility and pay.

Another advance was in the provision of numerous whole-time and permanent medical research posts. Forty years ago there was not a single pure medical research laboratory in India except D. D. Cunningham's in Calcutta. Now good work of a practical nature was being done in the Bombay Plague Laboratory, in the Calcutta School of Tropical Medicine and in the Hygiene Institute built by the Rockefeller Foundation, in the plains in association with hospitals, and in the hill-top laboratories.

Sir Leonard went on to say that the I.M.S. did not lack good candidates to-day. He was convinced that, thanks very largely to the sympathetic backing of the India Office, the I.M.S. would maintain its traditions as the finest medical service the world had ever seen.

Sir John Megaw, in proposing The Chairman, omitted any reference to his researches, as they were common knowledge in the Service, but he recited the achievement of founding in Calcutta a research institute in the face of every possible pretext for economy and delay; an admiring business man had remarked to him: "Rogers ought to have been a company promoter." He spoke of physical activities in keeping with mental activities, which included bicycling in Bengal and catching a burglar with his own hand. His optimism for the Service was only justified, Sir John said, by the magnificent efforts which he had himself made. Towards the end of the dinner Col. J. Anderson achieved the impossible by telling some new stories and stimulated Col. P. Dee and Lt.-Col. F. O'Kinealy to tell others. The staff work of the dinner secretaries was gratefully acknowledged, Sir Thomas Carey Evans simply replying: "As long as you have enjoyed yourselves it is our reward."

ROYAL NAVAL MEDICAL SERVICE

Surg. Lts. to be Surg. Lt.-Comdrs.: L. J. Corbett and H. J. McCann.

The following appointments are notified: Surg. Lts. H. A. Clarke and H. E. B. Curjel to *President*, for Medical Dept., Admiralty.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. (D) W. R. Young to be Surg. Lt.-Comdr. (D).

The following appointments are notified:—

Surg. Lt.-Comdr. W. F. Lascelles to *Valiant*.

Surg. Lt. J. F. Heggie to *Leander*.

Proby. Surg. Lt. P. K. Fraser to *Victory* for R.N.B.

Proby. Surg. Sub-Lt. W. S. Miller to *Victory*, for R.N.B.

ROYAL ARMY MEDICAL CORPS

Maj. T. H. Twigg is restd. to the estabt.

ARMY RESERVE OF OFFICERS

Lt. P. R. Wheatley from R. Signals to be Lt.

INDIAN MEDICAL SERVICE

Temp. Lts. to be Temp. Capts.: M. Hafizuddin and K. V. R. Choudari.

Lts. W. M. E. Anderson, H. B. Wright, and J. Scott relinquish their prob. appts.

Lt.-Col. A. D. White retires.

ROYAL AIR FORCE

E. Donovan is granted a short service commission as Flight Lieutenant for three years on the active list.

Flight Lt. M. Pearson relinquishes his temporary commission on completion of service.

CONTROVERSIAL ISSUES

THE CASE FOR ABOLITION OF COMPULSORY VACCINATION OF INFANTS

THE efficacy of vaccination for the prevention of small-pox is, for all practical purposes, outside the field of medical controversy. Practical experience in the control of epidemics and the dispassionate examination of the records of outbreaks of the disease are alike convincing on the point. They likewise demonstrate that *infant* vaccination, no matter how thoroughly it may be done, merely shifts the age-incidence and reduces the total mortality among those who contract the disease ; it fails to afford protection against the spread of small-pox in a community. Indeed, it complicates the administrative control of the disease by increasing the proportion of abortive, and therefore undiagnosed, cases, since many of those who have lost complete immunity retain sufficient to modify the disease almost beyond recognition. The total incidence in a community of people vaccinated in infancy, but not revaccinated, may therefore be greater than among a completely unvaccinated population subject to the same vigorous epidemiological surveillance. Hypothetically, therefore, the total death-rate from the disease may be as high or higher, although the case-mortality is substantially reduced.

These comments are, of course, made with special reference to the disease in the virulent form which has come to be called variola major. They constitute the main if not the whole case, from the scientific point of view, against infant vaccination in a community exposed to a real and constant risk of infection with variola major, and it is not a very strong one. Under such conditions no security can be assured by any other means than universal infant vaccination and periodic revaccination.

The question which besets our minds is whether *the risk we run in this country* is really great enough to counteract certain other disadvantages of infant vaccination, especially under compulsion. We are now largely an unprotected people in this country by neglect of infant vaccination and by loss of the immunity of the vaccinated as the result of lapse of time—although allowance must be made for the probable immunising influence of the mild type of the disease, now called variola minor, during the last ten years. Yet, although variola major has found a footing in several parts of the country, it has failed to establish itself, with the exception of the Glasgow epidemic of 1920–21. This, of course, is no guarantee that it might not flare out under conditions of increased invasiveness and if the proportion of immunes were still further reduced. We have seen, however, that its administrative control is, on the whole, easier, especially at the outset of an epidemic, if it is not complicated by the modification brought about by remote vaccination. On balance, the danger does not appear to be so great as to justify the continuance of a measure to which there is a rooted objection, whether that objection is based on solid grounds or upon mere prejudice.

Is there, then, any valid argument of a medical nature against vaccination ? No reasonable person can deny that there is. Vaccinia causes a great deal of discomfort and a certain amount of malaise in an appreciable proportion of those subjected to it. It kills some of them. There is no reason to suppose that the Registrar-General's statistics in this connexion are subject to greater error than in relation to any other disease, and they show that 59 persons died of vaccinia in the ten years, 1923–32, in England and Wales. In the same period, when small-pox, in the form of variola minor, was exceptionally prevalent and several small outbreaks of variola major occurred, 226 persons died of the disease, or less than four times the number of deaths from vaccinia. The number of notified cases of small-pox (major and minor forms not distinguished) was 79,410, so that the case-mortality from small-pox was as low as 0·28 per cent. It is true, of course, that the fatality of vaccinia was far lower, for there were approximately 2,900,000 vaccinations, and the percentage case-mortality was therefore about 0·002. But the risk in vaccination is there. The larger the amount of vaccination the greater the actual number of deaths, and it is reasonable to question the right of a community to enforce it upon parents, when the other risk against which it protects the children—for a limited period of years—is so much less in total volume.

The people of this country have answered the question. Exemptions on the ground of conscientious objection have increased in number until they constituted 46·7 per cent. of all births in 1931. From 1905 to 1931 the percentage of vaccinations to births fell from 75·8 to 39·0. The decline has been continuous, with a slight interruption in the earlier years of the recent wave of variola minor, before the true character of that disease was generally realised either by the profession or the public. There is not the shadow of a prospect of a reinforcement of compulsion except in the face of a grave epidemic of variola major and then, if it were to be effective, compulsion would have to be extended to revaccination as well.

A law which is not observed is worse than no law at all. It would probably not be difficult to secure the vaccination of most of the present 39 per cent. of infants, without any power of compulsion. Undoubtedly, and naturally, compulsory vaccination when it was enforced created the attitude of antagonism to all forms of artificial immunisation which dies hard among the people. And yet it is upon such measures that we shall probably have to rely for the eradication of the air-borne diseases, such as diphtheria, scarlet fever (if it ever again becomes so severe in type as to make it worth while), measles, whooping-cough, and perhaps influenza. How can we expect parents to welcome the new prophylaxis, with its measured dosage and almost complete freedom from danger, if we continue to try—or pretend—to force them to accept the inoculation of a virus capable of multiplying itself and producing a lesion which may be the centre of pyogenic infection, and which has other fatal sequelæ ?

Compulsion there may have to be from time to time. We cannot be sure that variola major will always treat us lightly as it has during the present century. The Minister of Health has power to enforce vaccination at any time or in any part of the country by Orders made in terms of Sections 130 and 134 of the Public Health Act, 1875. In fact, it would be found that, in face of a real danger the people would demand vaccination and enforcement would be necessary to quite a limited extent. It will be said that many would contract the disease and die before they could be protected. They would also if every child was vaccinated, but not subsequently revaccinated, and much more so in our present state of pseudo-vaccination. In fact, with the modern organisation of the profession, the growth of health departments, and the establishment of clinics, vaccination of the whole community in a few weeks would not be an impossible proposition. It may more reasonably be argued that the production of the requisite quantity of lymph of the correct degree of maturity would present difficulties. It certainly would but, in practice, the country would be taken area by area, as the spread of small-pox—a disease with a comparatively long incubation period—is not rapid. The laboratories at the Ministry of Health have shown during the years 1923 and 1924 that rapid expansion of their output is possible. It will certainly be said that delay in vaccination will increase the risk of post-vaccinal encephalitis. That is the present view, although it seems to await confirmation. Some experience of the errors in death certification among young infants makes one a little sceptical on the point, and the complication is so rare that time is required for the gathering of sufficient data. In any case, it is not the most important of the fatal complications of vaccinia, and its importance would be relatively less in the presence of an invasion of variola major.

Generally, it is reasonable to maintain that the compulsory imposition of a procedure which involves some danger to health and even to life, however slight, is permissible only if it assures the protection of the community as a whole, and not merely the individual. Infant vaccination, without revaccination, affords no such herd protection. If obligatory vaccination is necessary it should include revaccination of those who have lost immunity. That, under ordinary conditions, is not practically attainable but, in circumstances of imminent risk, exercise by the Minister of his power to make such an Order would not be seriously opposed.

The truth of the matter is that compulsory vaccination against a hypothetical danger is an obstacle to the acceptance of immunisation against present risks. There would appear to be no hope of the widespread adoption of artificial prophylaxis against other diseases, so long as a living virus is associated in the public mind with the process and its use is even nominally enforced. The whole problem would be altered if a dead antigen for producing immunity against small-pox were discovered and vaccination thus brought into line with the more modern methods of prophylaxis. Even then compulsion would be more of a hindrance than a help.

THE CASE AGAINST THE ABOLITION OF COMPULSORY VACCINATION OF INFANTS

The question of compulsory vaccination was raised last year by the Council of the British Medical Association and a resolution calling for its abolition was sent to the annual conference where, however, an amendment was accepted and the Council was asked to consider the matter again. This reference back supported the contention of the meeting of the Association of Public Vaccinators whose members are regularly inside the homes of those directly concerned—that there is no general demand for any alteration of the law. Those who advocate abolition bring forward no solid argument but only a purely hypothetical assumption that entire freedom would act as a magnet towards vaccination. Experience on parallel lines entirely negatives this. What does compulsory vaccination mean in these days ? It means the possibility of exerting administrative pressure where needed by statutory officials. It does not interfere with those individuals who, however misguidedly, choose to "contract out" from vaccination by the conscience clause. It also means that there exists an organisation constituted by law which keeps in operation the machinery necessary for the control of small-pox. Remove the compulsory idea and there is nothing except small-pox to prevent the population from forgetting all about vaccination. It is only the regular visitation by administrative officers which counteracts this forgetfulness or indifference, and these officers will disappear if there is no law to administer. Is it not better to have the present average of 40 per cent. (in some places over 60 per cent.) of the infants coming along vaccinated, thus putting up a barrier, even though an incomplete one, rather than have no barrier at all against small-pox ? Most medical officers of health would feel much happier if they knew that there was a 40 per cent. barrier against, say, diphtheria. Backing away from compulsion will accelerate indifference and furthermore would be interpreted as meaning that vaccination was no longer necessary. The abolition of the compulsory clauses—which apparently is only called for by those behind the office desk or the laboratory bench, not by those who actually go into the homes of the people and are therefore in a much better position to judge the psychological attitude of parents to the matter—would mean that the whole matter would be left to a largely unthinking public. Though the main aspects of the question are (*a*) the municipal and (*b*) the domestic, yet the abandonment of compulsion would have both an international and a national bearing.

Internationally, if the abolition of compulsion means, as seems likely, the abandonment of all administrative pressure, the Public Health Committee of the League of Nations would find the balance of its work in connexion with the control of small-pox disturbed. One nation would have deserted and there would be a breach in the wall of solid defence which the near-by nations at any rate had set up. Their opportunities to gauge effects would be narrowed, and their orbit of observation curtailed, and this by the very nation which gave vaccination to the civilised world.

Nationally the abolition of compulsion might strain both social and commercial relations with other countries especially if small-pox continues. Moreover the steady work of the National Lymph Establishment would be unbalanced if it had only to hold itself in readiness for peak loads due to sudden outbreaks of small-pox, with only an infinitesimal weekly call and no returns bearing on the reactions of lymph. Would the nation feel happy in the knowledge that its field army of administrators and propagandists no longer existed ?—for without compulsion no army would be required.

Municipal outlook.—If the individual ceases to be protected, then greater protection must be provided for the community. Epidemics will come, and all must be in readiness. There was not long ago an outbreak in Lancashire of the severer type. It is much less costly to prevent by vaccination than to overtake by hospital isolation. Once having lost the idea of the force which compulsory administration implies, both vaccination and revaccination will be spurned, and the well-vaccinated towns will involuntarily be dragged down to the level of the others. Would this be fair ?

Domestic outlook.—As is well known, persons having a rooted objection to vaccination can "contract out" by making a statutory declaration. The remainder available for vaccination can be divided into three classes :

1. Those anxious to have it done.
2. The indifferent, who await the call of the vaccination officer and after explanation of the reasons for vaccination, agree.
3. Those who say they would rather not have it done at all, but have been remiss or too indolent to get exemption. Many of these also comply after explanation.

As a last resort the vaccination officer has still the power of enforcement though it is very rarely exerted. Under a voluntary system, vaccinations would be confined to a portion of the first category only and in the absence of a general atmosphere of vaccination some even of these might recant. The voluntary system would certainly add to the number of the unvaccinated the enormous mass of the indifferent and careless. Propaganda would depend entirely on the complexion of the local governing body.

Summarising then much that has been said above, the following observations may perhaps act as pointers as to why compulsory vaccination should be retained.

1. The removal of the atmosphere of compulsion even without its legal enforcement would in the opinion of those most likely to know immediately lead to a decrease in the number of vaccinations.
2. It is the general opinion of the vaccination officials who actually go into the homes of those concerned that the compulsory clause does not now prevent a single person from accepting vaccination.
3. Public vaccinators hear no suggestion that but for compulsion parents would accept vaccination. On the other hand they are frequently told that it ought to be compulsory.
4. Abolition would immediately influence many who now regularly accept vaccination. Parents would argue that if it is not compulsory it is not now necessary.
5. The abolition of domiciliary vaccination which the dropping of compulsion implies would remove the opportunity for interviews with parents, by means of which many have been satisfied of the value of vaccination. Clinics would not provide such opportunities, and health visitors, who would not regard vaccination as their first duty, would largely fail to carry conviction.
6. The suggestion that entire freedom of choice would increase the number of vaccinations is unsupported by past experiences. When the Royal Commission suggested a conscience clause it predicted that the number of vaccinations would increase ; instead there was an almost immediate drop in the numbers in some places. Every relaxation has been followed by a decrease.
7. Judged by the very few coming forward voluntarily for immunisation against diphtheria, a disease which is still regarded with awe by most people and is seldom absent in any community, vaccination against a rare disease is even less likely to be considered in the absence of small-pox or of propaganda.
8. Removal of compulsion will react detrimentally to progress in regard to other immunisations, for it will certainly be loudly proclaimed that vaccination—the sire of all immunisations—has been found to be useless, however untrue this may be.
9. The missing of vaccination in infancy, when the chance of harmful effects is infinitesimal, will defer the primary operation to a later period when at any rate it may give more discomfort, and, anyhow, according to the last Royal Commission, the greater possibility of danger.
10. In the opinion of practitioners and officers who go into the homes of the people, there is no general demand for abolition.

Finally, once abandon compulsion, which means live administrative domiciliary pressure, and there is nothing left but the dead hand of indifference. There can be no turning back.

PANEL AND CONTRACT PRACTICE

Insurance of School Leavers

THE possibility of extending health insurance to cover children from the time they leave school was considered in our issue of May 19th (p. 1086), where comments were made on a resolution of the Birmingham insurance committee which has been circulated for comment. The proposal has since been brought before the annual conference of the National Association of Trade Union Approved Societies, and this body has decided in its favour. The conference added a rider, however, that the whole of the contributions for children of 14–16 should be paid by the employer and the State—a suggestion which would place the beneficiaries in a privileged position. In the discussion it was stated that the Government had no intention of raising the school-leaving age, and that if Unemployment Insurance were to apply between the ages of 14 and 16 it was only fair that health insurance should also be available for the same period. Of the thousands under the age of 16 who were engaged in distributive occupations many, it was urged, were in need of medical attention but could not afford it. To this the reply might be made that growth and multiplication of public medical service schemes makes it untrue to say any longer that juvenile workers cannot afford medical attendance.

As yet, however, there seems to have been no official expression of medical opinion on the subject.

Change of Doctor

The regulations on change of doctor are still inconsistent with the wishes of the profession, which has always held that a disgruntled doctor and a dissatisfied patient are best parted as soon as may be. At present an immediate change can be effected only when both practitioners give their consent or when the patient moves outside the two-mile radius of his medical attendant's practice. When a patient wishes to change doctors, without consent and without moving, he has to give at least a month's notice before the beginning of each quarter. He writes to the insurance committee enclosing his medical card, and the committee returns the card with a slip (printed in red ink and gummed to the inside) authorising the change. He takes this card, with the slip in it, to the new doctor of choice, who signs it in accepting the patient for his list, and it has then to be returned to the insurance committee by the new doctor within seven days. After registering the transfer the committee sends the insured person a new card with the new doctor's name on it. The former doctor is responsible for medical treatment up to the time of effective change—i.e., the beginning of the quarter. But as the patient is dissatisfied with *him*—otherwise he would not have made the change—it is unlikely that he will go to him for advice, and the probability is that he will have to pay for medic[illegible]mand [illegible] necessary, obtained elsewhere.

It will be seen that one local transfer involves four postages, two of which are paid for by the insurance committee, and this gives much clerical work to the committee. The London insurance committee has recently published its latest figures both for local changes—i.e., without consent and without moving away—and for all kinds of transfer in the course of the last year.

Taking the local changes first, for the quarter ending March, 1934, out of 1,786,954 insured persons on the lists of medical practitioners and institutions there were 7031 requests for change of doctor (without consent or moving away); of these, however, only 4929 were effective, for 1576 were irregular 313 being attempted out of time. In other words about 40 out of every 10,000 insured persons request this local change of doctor but only 27 carry it out in every quarter.

When we consider all the changes—i.e., the total transfers effected for all reasons in the year March, 1933–4—we find that out of an average of 1,884,526 insured persons on the medical register there were 23,319 requests to transfer of which 17,167 were effective. Reducing these to simpler figures 124 out of every 10,000 insured persons request the transfer, and for 91 out of every 10,000 it is effected. The total number of transfers by consent for the years from March, 1930 to 1934 is 38,681—not quite 10,000 per year.

The regulations provide that, save chronic illness in which he is certifying incapacity once a month, a practitioner cannot give notice to the insurance committee to have his patient removed from his list as long as that patient is ill and receiving certificates of incapacity to work; but he can give notice at any other time. The reason for this regulation seems to be fairly obvious. There have, however, been two cases recently before a medical service subcommittee in which doctors have apparently tried to get rid of their responsibility to attend an ill insured person by saying to the relatives "I cannot come," "It is too far away" (although within two miles), "I never visit in that area," "Let me have the medical card and I will sign the consent to transfer and you can then get the services of an insurance doctor without having to pay."

Practitioners under the insurance scheme are paid a capitation fee to look after their patients whether they are well or ill and to seek to transfer a patient, directly he becomes ill, to some other doctor who has received nothing for him when well is definitely unjustifiable. There may, of course, be special and quite genuine reasons why Dr. B. cannot respond immediately to a call to see his patient Mr. P., but this does not make it permissible for Dr. B. to try to transfer the patient by consent to Dr. C., nor does it justify Dr. B. telling the relatives to try to get Dr. C. to attend. What he ought to do is ring up or send a note to Dr. C., asking him to attend Mr. P. on his behalf, and he should arrange to pay Dr. C. the proper fees for doing his work.

It often becomes obvious that a patient is never likely to get on well with his doctor. If so, the best plan is to give notice to have him removed from the list before there is any trouble.

OBITUARY

ARTHUR ANDREW MORRISON, C.M.G., M.D. Aberd.

WE regret to announce that the death occurred on June 14th of Dr. Arthur Morrison, lately British consular surgeon at Alexandria, and well known in Egypt through 50 years of work as doctor and public official.

Morrison was born in 1858 in Aberdeen and educated at the grammar school of that city and Marischal College. He graduated as M.B., C.M. in 1882, and in the following year went to Alexandria as assistant to the late Sir James Mackie. In 1886, the year in which he proceeded to the M.D. degree, he was nominated R.M.O. to the State Hospital at Suez, where he worked until 1891, when he rejoined Mackie in Alexandria, and a few years later succeeded him as British consular surgeon and delegate on the Quarantine Board. He was also appointed surgeon to the Deaconess Hospital, now and since the war known as the Anglo-Swiss Hospital. This hospital received many Australian sick on their arrival at the seat of war, while in 1915 the wounded in the Gallipoli campaign soon began to fill the beds. Morrison won admiration on all sides by the strenuous way in which he tackled the administrative difficulties, and by his great skill as an operating surgeon. At the conclusion of the war he organised the Anglo-Swiss Hospital as a modern British institution, furnishing a chemico-bacteriological department at his own expense, and when at the age of 70 he retired from practice with the distinction of C.M.G., he remained a medical director of the institution and retained his delegateship on the Quarantine Board. In memory of his wife, who was the daughter of Capt. W. H. Roberts, of Suez, and whom he married during his service at that port, he founded at the hospital an anti-rabies institute which has proved of great service to the country and which will constitute a fine tribute to his memory.

ALAN DEED BRUNWIN, M.D., B.Chir. Camb.

THE death occurred in St. Thomas's Hospital, London, on June 21st, of Dr. A. D. Brunwin, a consultant tuberculosis officer for the county of Lancashire.

Alan Deed Brunwin was born at Rayne, Essex, in 1879, and was educated at Felsted and Trinity College, Cambridge. He went to St. Thomas's Hospital to finish his medical training, and graduated as M.B., B.Chir. in 1906. He proceeded to the M.D. in 1909, taking also the D.P.H. Aberd., and after certain resident appointments he entered the Colonial Service as Government M.O., Fiji. He recorded his experiences there by contributions to the medical press upon filariasis and dysentery, but his stay in the islands was brief, and before the war he returned to England to act as assistant medical officer at the Westmoreland Sanatorium. In 1913 he joined the medical staff of the Lancashire county council as consultant tuberculosis officer, the appointment being held jointly with the Blackpool corporation. He joined up at the outbreak of war as a temporary officer in the R.A.M.C., and was later attached as heart specialist to the base hospital at Etaples, where he did useful work on electrocardiography. At the cessation of hostilities he was given control of one of the five large dispensary areas in Lancashire, containing a special hospital for pulmonary diseases in that city with dispensaries at Preston and Chorley. With the coöperation of the late Dr. Logan Stewart he did interesting pioneer work in regard to the treatment of tuberculosis by artificial light at centres established in the tuberculosis dispensaries, the results of which he later published.

Dr. Brunwin will be greatly missed by his immediate colleagues and by the general practitioners of his district with whom he was always on friendly relations. He is survived by a widow and two children.

CORRESPONDENCE

INFANTILE DIARRHŒA

To the Editor of THE LANCET

SIR,—I was much interested in the paper by Dr. Maizels and Dr. Jean Smith in your last issue. The profession have been slow in recognising the importance of this subject. The authors say that the mortality in enteritis is over 50 per cent. I agree with this estimate, and would add that these cases do not do well in hospital; they are very liable to become infected with other organisms whilst in the overcrowded wards. It is, moreover, well known that enteritis cases are very apt to infect a whole ward of children which previously showed no symptoms of intestinal disturbance. I therefore think that these enteritis cases should be kept out of hospitals as much as possible and treated in the early stages in their own homes. Unfortunately the profession are not of one mind in regard to the principles of treatment. This is largely due to our ignorance of what is taking place in the child's body, and we should be grateful for any light which can be thrown on the problem by recent biochemical research. Acidosis no doubt exists, but the degree of acidosis does not seem to influence the prognosis in these cases. At what stage in the disease does the acidosis show itself, and how are we to diagnose the condition clinically? It is of course quite impossible to make elaborate blood examinations in the home; it is useless to examine the urine; and by the time the child becomes restless and has air-hunger the case is probably hopeless. One fact of practical importance that emerges from these researches is that normal saline must not be given, since this increases acidosis; half-normal saline can be safely given combined with glucose. This latter practice was adopted many years ago by the clinicians, and it is satisfactory to have this opinion confirmed by the biochemist.

Ten years ago I started a scheme in North Kensington for treating cases of acute vomiting and diarrhœa in their own homes amongst those who could not afford doctors' fees. Details of the scheme appeared in THE LANCET (1927, i., 176). It was made a notifiable disease, and with the help of the district nurses the scheme has worked very well. It seemed to me that as the child was losing so much fluid from its body, and as that fluid must come from the blood stream, the obvious thing was to introduce as much water as possible directly after the vomiting ceased, with the addition of sodium chloride, as this salt forms such an important constituent in the blood. I chose half-normal saline because this is more rapidly absorbed from the intestine than full-strength saline. Bottles full of saline were given to the infant during the first 24 hours; the child was encouraged to drink as much as possible; for instance, a baby 3 months old will take a pint of fluid in the 24 hours. One teaspoonful of castor oil was given, and the bowel was washed out with saline. The next day a food low in fat and high in sugar was given. I tried at first various foods, such as diluted lactic acid milk; this, however, was not easy to prepare in the home. Protein milk was fairly successful, but ultimately I hit on malted milk, which seemed to suit these cases better than anything else. It consists of water 3·7, protein 13·8, fat 9, carbohydrate 70·8; it is a mixture of desiccated milk, wheat flour, barley malt, sod. bicarb., and contains no unaltered starch. The child is generally kept on this mixture for five or six days, and then a very gradual return is made to a well-balanced diet. At first cow's milk is added to the malted milk in half-drachm doses. The greatest danger in these cases is to prolong starvation beyond the second day. I find it makes a great difference in the prognosis if the treatment is delayed beyond the third day of the illness. The prognosis is much more favourable if half-normal saline has been taken by the mouth instead of plain water. The dehydration is enormously relieved in the great majority of cases and temperatures of 103°–104° F. gradually subside.

It was encouraging to have my clinical experience confirmed by biochemical research. In a paper which appeared in THE LANCET (1930, i., 286) on Alkalosis in Congenital Hypertrophic Stenosis, Maizels, McArthur, and Payne described the examination of 34 cases, of which 28 had an increased bicarbonate reserve at some period before operation. They say the body has need of the chloride ion. In the vast majority of cases that I have seen the vomiting begins before the diarrhœa, as they are usually infants suffering from a dietetic cause, and are probably at first at any rate suffering from alkalosis and not acidosis; hence the success of treatment in these cases where vomiting is the prominent symptom. In this district the nurses have attended 836 cases in ten years; 8 of these died whilst the nurses were in attendance, and 26 died in hospital, making a total of 34 deaths, about 4 per cent. I cannot help feeling that the death-rate from enteritis could be very greatly reduced if some such scheme as this were adopted in large towns with a good district nurse service.

I have seen occasional outbreaks of dysentery, chiefly the Sonne variety; these cases are rarely fatal. The bacteriologist can of course help us in the diagnosis of dysentery, but in most cases of enteritis no specific organism can be isolated. I have seen a great number of post-mortems on these cases at St. Mary Abbot's Hospital; the most marked characteristic was the fatty degeneration of the liver and kidneys. Very often there was no sign of inflammation in the intestine. I have seen five cases of otitis media where the diarrhœa soon subsided after the appearance of pus from the ear. I do not regard otitis media as a cause of enteritis, but as a complication.—I am, Sir, yours faithfully,

Kensington, June 26th. RONALD CARTER.

RHEOSTOSIS

To the Editor of THE LANCET

SIR,—In her interesting paper on Familial Chondrodystrophy with Rheostosis (THE LANCET, Jan. 20th, 1934, p. 122) Dr. Gwenda Hilton mentioned that the condition of the long bones in her case differed from that first described by Léri and Joanny (1922) as "melorheostosis" in that it was bilateral and affected both upper and lower extremities. However, what I now believe to be a certain case of melorheostosis (or "rheostosis" as Dr. Hilton rightly prefers to call it) was brought before the Section for the Study of Disease in Children, Royal Society of Medicine, in May, 1920, by Dr. E. A. Cockayne (*Proceedings*, 1919–1920, xiii., 132–136) before Léri and Joanny wrote on the subject. In Cockayne's case the bone condition was *bilateral* and all four extremities were affected. The radiographic report stated: "Both femora show marked irregular thickening with formation of new dense bone throughout their length. There is a similar condition of osteitis in both humeri, especially in lower part; small local areas of thickening are present in both tibiæ and in one fibula; bones of forearms, hands and feet are normal." The Wassermann reaction in the blood of the patient (a boy, aged 9½ years) and in that of his father was negative (his mother was dead). The radiographic appearance in the femora is well illustrated by one of Dr. Cockayne's figures.

I had forgotten that Dr. Cockayne had described the case I am referring to when I first read Dr. Hilton's paper. I am, Sir, yours faithfully,

London, W., June 21st. F. PARKES WEBER.

HYDATID DISEASE OF THE LUNG

To the Editor of THE LANCET

SIR,—In your issue of June 16th (p. 1281) Dr. R. G. Prosser Evans advocates expectant treatment of pulmonary hydatid disease, and he records a case so treated which fortunately recovered. It is, I think, unfortunate that the views of H. Dew do not appear to have been considered. Basing his judgment on an unrivalled experience in Victoria, Dew insists upon early operative interference in all subpleural cysts and only countenances expectant treatment in the case of deeply situated parabronchial cysts which are neither large or causing toxæmia. "The prognosis after operations for simple pulmonary cyst is," he writes, "universally good and the mortality is under 5 per cent.; it is not so good in suppurating cases in which the mortality varies from 15 per cent. to 20 per cent." ("Hydatid Disease," Sydney. 1928). These results have been obtained by general surgeons without any other special experience in thoracic surgery.

The inference that the operative mortality in children is unduly high cannot be allowed to pass unchallenged. Although having no personal experience of hydatid disease, I have removed successfully a pulmonary lobe from a child aged 3 years and at present have under my care a girl aged 13 years who has survived, without serious inconvenience, a resection of the entire left lung carried out nine weeks ago. The view that young subjects, as a rule, tolerate major thoracic operations at least as well—if not better—than adults, is supported by the experience of Haight, Nissen and Rienhoff[1] who have performed successfully total pulmonectomies on children, aged 13, 8, and 3 years respectively.

Thoracic surgery has made, in this country, very slow progress, and gloomy views as to its scope are likely to prove a further check if undisputed. Otherwise criticism of Dr. Evans's interesting and instructive case would be unnecessary.

I am, Sir, yours faithfully,

GEORGE A. MASON.

Newcastle-upon-Tyne, June 20th.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Royal Assent

IN the House of Lords on Friday, June 22nd, the Royal Assent was given to a number of Acts, including the Workmen's Compensation (Coal Mines) Act: the Statutory Salaries (Restoration) Act; and the Birmingham United Hospital Act.

Supply of Milk to School-children

The Milk Bill was considered by the House of Commons in Committee on June 19th. Captain BOURNE was in the chair.

Sir FRANCIS ACLAND moved an amendment to provide that not less than half of the moneys provided by Parliament should be expended in repayment to the Milk Board in respect of milk for consumption by children attending public elementary schools, or by mothers, or by children under school age attending clinics under schemes approved by the local public health authority.

After some debate.

Mr. ELLIOT (Minister of Agriculture) said that the proportion of money which they would spend for the purposes mentioned in the amendment was much more like six-sevenths than *one-half* or *two-thirds*. In view of this assurance he hoped that the amendment would not be pressed, because the mere existence of these words might be taken by the bodies concerned as an indication that the House of Commons desired them to reduce the amount of expenditure on milk for school-children, and so on, and to enlarge considerably the amount spent in milk publicity.

The amendment was withdrawn.

On the question that Clause 11 (Contributions from the Exchequer towards the expenses of milk marketing boards),

Mr. ELLIOT, replying to Sir S. Cripps, who asked for further information as to the expenditure of the money to be allocated under the clause, said that he intended to work on the schemes which had been in operation for some time under the National Milk Publicity Council. Those schemes, which were now supplying something like 900,000 children with milk, were working well and by building on the existing foundation they would have the benefit of previous experience. Milk was being supplied while the children were attending school and that was the line along which the initial arrangements, at any rate, would be made. The method was to supply a separate bottle to each child with a straw through which to consume the milk. That made sure of absolute cleanliness and of slow absorption of the milk, which made it more easily digested. They had set before themselves the ideal of at once halving the price charged to schools. Milk was at present supplied at one penny for one-third of a pint, and they hoped as soon as they got the sanction under this Bill to reduce that price for the milk to one half-penny. That would apply to all those who were already receiving milk and to all new entrants. They hoped that this would act as an excellent advertisement. The extent to which they could spread the milk at one half-penny depended on the arrangements the Board were able to make with the distributors.

The clause was ordered to stand part of the Bill.

The Committee stage was concluded and the Bill as amended was reported to the House.

Noxious Fumes in London Streets

In the House of Lords on Wednesday, June 20th, Lord KILMAINE called attention to the congestion of traffic in the London streets.

The Earl of DENBIGH said that one of the results of the awful congestion in the streets was the harm which was being done by the poisonous atmosphere. There were all sorts of regulations against cars being allowed to emit visible exhaust fumes, but what was the use of such regulations if nothing was done?

Earl HOWE said he did not believe that it was realised how much the air in the London streets was poisoned by exhaust fumes. He believed that the medical profession had carried out tests and they had found that there was an appreciable amount—he had heard quite high figures—of carbon monoxide in the blood of policemen who were employed in directing traffic. He believed that in New York they had attempted to tackle this matter and attempted to ventilate their streets through the drains and the sewers.

The Earl of PLYMOUTH, replying to the debate on behalf of the Government, said he would undertake to bring this matter to the notice of the Minister of Transport and he felt sure he would give it his consideration.

Public Health Services: Minister's Review

On Wednesday, June 20th, the House of Commons went into Committee of Supply on the Civil Estimates, Captain BOURNE, Deputy Chairman of Committees, in the chair.

On a vote of £13,639,924 for the salaries and expenses of the Ministry of Health.

Sir HILTON YOUNG (Minister of Health) said that this year there was an increase of £18,500 in the administrative expenses of the Ministry in connexion with slum clearance and rural water-supplies. There was an increase of £167,000 in respect of housing grants, and in respect of miscellaneous grants there was an increase of £199,000. Between the years 1919 and 1934 the Vote for the Ministry of Health had increased by the enormous figure of £58,000,000. Nearly half of the great increase in the vote had been caused by the De-rating Act. It had nothing to do with social services; it simply represented a change of expenditure from the local to the central pockets of the State.

Last year he dealt with the aspect of national health which was summarised in the word "nutrition," a matter in which it was difficult to give positive proofs. This year he would deal with the standard of national physique and health as shown by the incidence of disease in the country, and the resistance of the population to disease. On this matter it was possible to give very much more positive information, because it was reflected much more in actual figures. The most conclusive figure was the general death-rate, which was very sensitive to the general effects of epidemics and diseases. It took a sharp and marked rise in the influenza year of 1929. The general death-rate of the nation showed an encouraging downward tendency, which was the best proof of general maintenance of national health and physique. In comparison with five years before the standardised death-rate for 1932 stood 10 per cent. lower. That was an improvement in the death-rate after taking account of the fact that the population, owing to the falling death-rate, was annually getting older in its average age. The death-rate was a standardised death-rate which allowed for any increase in the age of the population. The next figure showed a more positive and encouraging result from the nation's great outlay of energy and money on health services, and that was the infant death-rate. During the last ten years, owing to the improvement in the infant death-rate, they had saved 40,000 more infants under one year than was the case at the beginning of the century, and the figures for the ten years at the beginning of the century were a great improvement on those of any preceding such period. This encouraging result was due, as the technicians said, to improvement in environment. The environment of an infant under one year was more than anything else its mother, and the improvement he referred to was, he believed, due basically to the improvement in the education of the mothers in the care of infants.

He offered a word of tribute to the magnificent work done by the 1340 antenatal clinics and the 2820 infant welfare centres. There was nothing which gave a firmer personal conviction of the value of health work than what one saw at these centres. Nor could he pass over the thousands of health visitors and nurses who carried from these centres the good work into the homes of the people. In the last fifteen years they had cut down the death-rate of children under 5 years of age from the three diseases most fatal to children—namely, bronchitis, diarrhœa, and measles—by more than one-half. If they looked not only to children but to adults they saw a good result from the faithful work of the medical profession and the hospitals, and of the administrators in the public health services over the whole field of local and central government. Where one person died of whooping-cough in 1932, nearly four died at the beginning of the century; where one died of diphtheria four died at the beginning of the century; where one died in 1932 of scarlet fever, over seven were dying at the beginning of the century. The most remarkable scientific result of all, attributable to the public health work, was shown by the fact that where one person died in 1932 of typhoid, the number who died at the beginning of the century was 22. The brilliant successes made in this field were shown whenever they came to outside carriers like water or milk, or some bug or insect, or food. The difficulties arose where infection was carried from person to person. It was known to science that there were constantly great waves of infection of these diseases passing through the public which never broke. The microbes were there and grew and declined, but the infection did not break in actual cases of disease. These waves were very difficult to check in order to stop a break of the disease. It followed from that, that since the difficulty of checking these diseases was greatest in cases where it was person to person infection; what they had to work on in order to prevent the diseases was to see that persons were not crowded too closely together. If they put their finger on overcrowding as an evil that clamoured for a national remedy they did so not only in a social sense, but in order to prevent disease. In the ten years up to 1933 the death-rate from tuberculosis had been decreased by 22 per cent. However far the success against tuberculosis was carried, they would never get rid of it until they finally got rid of the slums, which were the refuges of the disease.

The statistics as regards lunacy and mental deficiency might give a less favourable impression. The apparent increase in lunacy was deceptive, because it was a disease of advanced years; and it was probable that the increased average age of the population accounted for the increase of lunacy, rather than any actual increase of the disease. There had been an apparent enormous increase in mental deficiency, but this apparent increase was really due to better ascertainment. During the year there had been a most interesting and unanimous report on the difficult problem of sterilisation, and he was profoundly impressed by the strength of the reasons given by the committee in support of their recommendations as to sterilisation. As far as his own individual conscience was concerned he could see not the least difficulty in approving the recommendations of the Committee. But as regarded ministerial responsibility, they must remember that this was a novel question and one which had not yet been thought out by the mind and heart of the nation. At present, consideration was being given to the report by great organisations of national opinion, such as the churches. It would be wrong for him to propose any national policy in the matter until there had been sufficient time for the national mind and conscience to be cleared.

The maternity death-rate had not decreased like other death-rates during the last 20 years, and that was not satisfactory. They had obtained more knowledge of the question by intensive study, and they knew that the death-rate had not decreased owing to bad local patches in maternity welfare work. He urged the responsible authorities in those localities where the maternity death-rate was above the normal to follow up and intensify inquiries as to the cause of the local variation. There was an increase of 147 more antenatal clinics, and an increasing number of births now took place under the supervision of those clinics. There was also an increase in the number of maternity beds, and he wished to pay special tribute to the success of the London County Council in increasing their maternity service. The work done in connexion with the health services had been very much assisted by the systematic review of those services by the Ministry of Health. Two things were particularly sought in these reviews besides a general increase in efficiency. First they wanted to press forward with the movement inaugurated by the Act of 1929 for taking the treatment of disease out of the poor-law. Good progress had been made in the transfer of institutions dealing with ill-health from the public assistance to the public health committees in London, where 60 institutions had been taken out of the poor-law. Another great advantage was the specialising of institutions.

Referring to the drought, Sir Hilton Young said when the crisis was over they would profit by the experience of the great drought in order to see what could be done to insure against similar emergencies in the future.

The year had been one of tremendous activity in housing, and in particular with the slum clearance campaign. If this rate of acceleration was maintained they would achieve the programme of the White Paper in five years. But they must speed up the rate of demolition still more in order to reach that result. From his knowledge of the progress being made and the vigour which the local authorities were putting into the matter, he could say that unless there was any setback the rate of progress achieved encouraged one to believe that five years would see the programme substantially carried out. At the Ministry the town-planning and the housing work were now in a single department under an officer with the special status of Director of Housing. Forty thousand more houses were built in the half-year ended March 31st than in the preceding half-year, and 77,000 houses were built in the half-year for the lower-paid wage-earners. They were now building houses at the rate of 300,000 houses a year, and at the rate of 155,000 a year for the lower paid wage-earners.

Mr. GEORGE GRIFFITHS urged the Minister of Health to see that diabetic people who had fallen out of medical benefit should continue to get their insulin free, as they had done in the past.

Captain ELLISTON asked what the intentions of the Government were with regard to the British Post-Graduate Hospital and Medical School. He said that before the financial crisis of 1931 £250,000 had been voted for the provision and equipment of this hospital and school. After the crisis that sum was reduced to £100,000, but many leaders of British medicine hoped that now that the financial strain was less acute the Government would take a more liberal view of the possibilities in this connexion. They wanted to see in London a post-graduate medical school which was not only worthy of British medicine, but which would be a central rallying point for medical men from all parts of the Empire and the United States, which sent over hundreds of students every year to graduate in the medical schools of Paris, Vienna, Berlin, and Rome. They left London out because the teaching facilities here were so ill-organised and inadequate. There was in London material which would rival that of any capital in Europe.

The health departments of this country were so fully organised and equipped, and so ably administered, that there was very little more that could be done to increase their efficiency. It only remained to teach the public to make use of those facilities. He appealed to the Minister to advise local authorities that a small expenditure in education would mean a great saving in the cost of public health departments and in preserving the health of the people. It was a great hardship in the local government service that superannuation was in force in only some areas, and he urged that a measure enforcing universal superannuation for local government officers should be undertaken by the Government.

After further debate the further consideration of the Vote was adjourned.

Overhead Tramways and London Hospital

On consideration of the London Passenger Transport Board Bill, as amended by Select Committee, in the House of Commons on Wednesday, June 20th,

Dr. O'DONOVAN moved to leave out Clause 33 of the Bill, which gives power to work Aldgate to Grove-road tramway on the overhead system. He said that this tramway line ran through the biggest thoroughfare of London, having on one side the greatest hospital in London. It would be a pity if this clause should fasten upon the locality of Stepney a transport system which might be well suited to the large dormitory villages across the Lea, but trams should not be encouraged to carry these ancient trolleys up the fine Mile End-road. They would be noisy, and sleep was precious. This great road was already a road of slaughter, and the borough council and the people of the district felt that posts would not add to its safety.

Mr. JANNER said that it was not a light matter to interfere with a hospital such as the London Hospital.

Sir G. HAMILTON said that he knew that overhead equipment could be made practically silent. He was certain that if the London Hospital had any feeling against overhead equipment they would have let the promoters know.

Dr. O'DONOVAN said that he was a physician on the active staff of that hospital and his own patients slept in a ward aligned against the Mile End-road. If Sir G. Hamilton would offer new trams he would withdraw what he had said, but he knew these ancient vehicles.

Sir G. HAMILTON said that they were not dealing with the ancient trams, but with new overhead equipment. That equipment would not cause any noise which would disturb the patients of the London Hospital.

Dr. O'DONOVAN said that he would withdraw his amendment because there were other and constitutional means open to a borough council but not open to a Member of Parliament which could be employed to test the feeling of Parliament on this matter.

The amendment was by leave withdrawn and the Bill was read the third time.

The Milk Bill and Pasteurisation

On June 25th in the House of Commons the Milk Bill was considered on Report.

On Clause 9 (payments for securing pure milk-supply),

Sir S. CRIPPS moved an amendment giving the Minister of Agriculture and the Secretary for Scotland power to exercise the powers conferred on local authorities under the Diseases of Animals Acts, 1894 to 1927, or any orders or regulations made thereunder, in the case of default of any local authority. He said that there were counties where there was very little inspection of dairy herds, while in others it was more systematic. If this power was given it would be very valuable.

Mr. ELLIOT, Minister of Agriculture, said that the confusion that would be caused by saying that the Ministry of Agriculture should carry out a duty which normally belonged to a local authority would be the worst possible thing in the administration of this scheme.

After further debate the amendment was negatived by 209 votes to 49.

Noxious Fumes in London Streets

In the House of Lords on Wednesday, June 20th, Lord KILMAINE called attention to the congestion of traffic in the London streets.

The Earl of DENBIGH said that one of the results of the awful congestion in the streets was the harm which was being done by the poisonous atmosphere. There were all sorts of regulations against cars being allowed to emit visible exhaust fumes, but what was the use of such regulations if nothing was done ?

Earl HOWE said he did not believe that it was realised how much the air in the London streets was poisoned by exhaust fumes. He believed that the medical profession had carried out tests and they had found that there was an appreciable amount—he had heard quite high figures—of carbon monoxide in the blood of policemen who were employed in directing traffic. He believed that in New York they had attempted to tackle this matter and attempted to ventilate their streets through the drains and the sewers.

The Earl of PLYMOUTH, replying to the debate on behalf of the Government, said he would undertake to bring this matter to the notice of the Minister of Transport and he felt sure he would give it his consideration.

Public Health Services : Minister's Review

On Wednesday, June 20th, the House of Commons went into Committee of Supply on the Civil Estimates, Captain BOURNE, Deputy Chairman of Committees, in the chair.

On a vote of £13,639,924 for the salaries and expenses of the Ministry of Health.

Sir HILTON YOUNG (Minister of Health) said that this year there was an increase of £18,500 in the administrative expenses of the Ministry in connexion with slum clearance and rural water-supplies. There was an increase of £167,000 in respect of housing grants, and in respect of miscellaneous grants there was an increase of £199,000. Between the years 1919 and 1934 the Vote for the Ministry of Health had increased by the enormous figure of £58,000,000. Nearly half of the great increase in the vote had been caused by the De-rating Act. It had nothing to do with social services ; it simply represented a change of expenditure from the local to the central pockets of the State.

Last year he dealt with the aspect of national health which was summarised in the word " nutrition," a matter in which it was difficult to give positive proofs. This year he would deal with the standard of national physique and health as shown by the incidence of disease in the country, and the resistance of the population to disease. On this matter it was possible to give very much more positive information, because it was reflected much more in actual figures. The most conclusive figure was the general death-rate, which was very sensitive to the general effects of epidemics and diseases. It took a sharp and marked rise in the influenza year of 1929. The general death-rate of the nation showed an encouraging downward tendency, which was the best proof of general maintenance of national health and physique. In comparison with five years before the standardised death-rate for 1932 stood 10 per cent. lower. That was an improvement in the death-rate after taking account of the fact that the population, owing to the falling death-rate, was annually getting older in its average age. The death-rate was a standardised death-rate which allowed for any increase in the age of the population. The next figure showed a more positive and encouraging result from the nation's great outlay of energy and money on health services, and that was the infant death-rate. During the last ten years, owing to the improvement in the infant death-rate, they had saved 40,000 more infants under one year than was the case at the beginning of the century, and the figures for the ten years at the beginning of the century were a great improvement on those of any preceding such period. This encouraging result was due, as the technicians said, to improvement in environment. The environment of an infant under one year was more than anything else its mother, and the improvement he referred to was, he believed, due basically to the improvement in the education of the mothers in the care of infants.

He offered a word of tribute to the magnificent work done by the 1340 antenatal clinics and the 2820 infant welfare centres. There was nothing which gave a firmer personal conviction of the value of health work than what one saw at these centres. Nor could he pass over the thousands of health visitors and nurses who carried from these centres the good work into the homes of the people. In the last fifteen years they had cut down the death-rate of children under 5 years of age from the three diseases most fatal to children—namely, bronchitis, diarrhœa, and measles—by more than one-half. If they looked not only to children but to adults they saw a good result from the faithful work of the medical profession and the hospitals, and of the administrators in the public health services over the whole field of local and central government. Where one person died of whooping-cough in 1932, nearly four died at the beginning of the century ; where one died of diphtheria four died at the beginning of the century ; where one died in 1932 of scarlet fever, over seven were dying at the beginning of the century. The most remarkable scientific result of all, attributable to the public health work, was shown by the fact that where one person died in 1932 of typhoid, the number who died at the beginning of the century was 22. The brilliant successes made in this field were shown whenever they came to outside carriers like water or milk, or some bug or insect, or food. The difficulties arose where infection was carried from person to person. It was known to science that there were constantly great waves of infection of these diseases passing through the public which never broke. The microbes were there and grew and declined, but the infection did not break in actual cases of disease. These waves were very difficult to check in order to stop a break of the disease. It followed from that, that since the difficulty of checking these diseases was greatest in cases where it was person to person infection, what they had to work on in order to prevent the diseases was to see that persons were not crowded too closely together. If they put their finger on overcrowding as an evil that clamoured for a national remedy they did so not only in a social sense, but in order to prevent disease. In the ten years up to 1933 the death-rate from tuberculosis had been decreased by 22 per cent. However far the success against tuberculosis was carried, they would never get rid of it until they finally got rid of the slums, which were the refuges of the disease.

The statistics as regards lunacy and mental deficiency might give a less favourable impression. The apparent increase in lunacy was deceptive, because it was a disease of advanced years ; and it was probable that the increased average age of the population accounted for the increase of lunacy, rather than any actual increase of the disease. There had been an apparent enormous increase in mental deficiency, but this apparent increase was really due to better ascertainment. During the year there had been a most interesting and unanimous report on the difficult problem of sterilisation, and he was profoundly impressed by the strength of the reasons given by the committee in support of their recommendations as to sterilisation. As far as his own individual conscience was concerned he could see not the least difficulty in approving the recommendations of the Committee. But as regarded ministerial responsibility, they must remember that this was a novel question and one which had not yet been thought out by the mind and heart of the nation. At present, consideration was being given to the report by great organisations of national opinion, such as the churches. It would be wrong for him to propose any national policy in the matter until there had been sufficient time for the national mind and conscience to be cleared.

The maternity death-rate had not decreased like other death-rates during the last 20 years, and that was not satisfactory. They had obtained more knowledge of the question by intensive study, and they knew that the death-rate had not decreased owing to bad local patches in maternity welfare work. He urged the responsible authorities in those localities where the maternity death-rate was above the normal to follow up and intensify inquiries as to the cause of the local variation. There was an increase of 147 more antenatal clinics, and an increasing number of births now took place under the supervision of those clinics. There was also an increase in the number of maternity beds, and he wished to pay special tribute to the success of the London County Council in increasing their maternity service. The work done in connexion with the health services had been very much assisted by the systematic review of those services by the Ministry of Health. Two things were particularly sought in these reviews besides a general increase in efficiency. First they wanted to press forward with the movement inaugurated by the Act of 1929 for taking the treatment of disease out of the poor-law. Good progress had been made in the transfer of institutions dealing with ill-health from the public assistance to the public health committees in London, where 60 institutions had been taken out of the poor-law. Another great advantage was the specialising of institutions.

Referring to the drought, Sir Hilton Young said when the crisis was over they would profit by the experience of the great drought in order to see what could be done to insure against similar emergencies in the future.

The year had been one of tremendous activity in housing, and in particular with the slum clearance campaign. If this rate of acceleration was maintained they would achieve the programme of the White Paper in five years. But they must speed up the rate of demolition still more in order to reach that result. From his knowledge of the progress being made and the vigour which the local authorities were putting into the matter, he could say that unless there was any setback the rate of progress achieved encouraged one to believe that five years would see the programme substantially carried out. At the Ministry the town-planning and the housing work were now in a single department under an officer with the special status of Director of Housing. Forty thousand more houses were built in the half-year ended March 31st than in the preceding half-year, and 77,000 houses were built in the half-year for the lower-paid wage-earners. They were now building houses at the rate of 300,000 houses a year, and at the rate of 155,000 a year for the lower paid wage-earners.

Mr. George Griffiths urged the Minister of Health to see that diabetic people who had fallen out of medical benefit should continue to get their insulin free, as they had done in the past.

Captain Elliston asked what the intentions of the Government were with regard to the British Post-Graduate Hospital and Medical School. He said that before the financial crisis of 1931 £250,000 had been voted for the provision and equipment of this hospital and school. After the crisis that sum was reduced to £100,000, but many leaders of British medicine hoped that now that the financial strain was less acute the Government would take a more liberal view of the possibilities in this connexion. They wanted to see in London a post-graduate medical school which was not only worthy of British medicine, but which would be a central rallying point for medical men from all parts of the Empire and the United States, which sent over hundreds of students every year to graduate in the medical schools of Paris, Vienna, Berlin, and Rome. They left London out because the teaching facilities here were so ill-organised and inadequate. There was in London material which would rival that of any capital in Europe.

The health departments of this country were so fully organised and equipped, and so ably administered, that there was very little more that could be done to increase their efficiency. It only remained to teach the public to make use of those facilities. He appealed to the Minister to advise local authorities that a small expenditure in education would mean a great saving in the cost of public health departments and in preserving the health of the people. It was a great hardship in the local government service that superannuation was in force in only some areas, and he urged that a measure enforcing universal superannuation for local government officers should be undertaken by the Government.

After further debate the further consideration of the Vote was adjourned.

Overhead Tramways and London Hospital

On consideration of the London Passenger Transport Board Bill, as amended by Select Committee, in the House of Commons on Wednesday, June 20th,

Dr. O'Donovan moved to leave out Clause 33 of the Bill, which gives power to work Aldgate to Grove-road tramway on the overhead system. He said that this tramway line ran through the biggest thoroughfare of London, having on one side the greatest hospital in London. It would be a pity if this clause should fasten upon the locality of Stepney a transport system which might be well suited to the large dormitory villages across the Lea, but trams should not be encouraged to carry these ancient trolleys up the fine Mile End-road. They would be noisy, and sleep was precious. This great road was already a road of slaughter, and the borough council and the people of the district felt that posts would not add to its safety.

Mr. Janner said that it was not a light matter to interfere with a hospital such as the London Hospital.

Sir G. Hamilton said that he knew that overhead equipment could be made practically silent. He was certain that if the London Hospital had any feeling against overhead equipment they would have let the promoters know.

Dr. O'Donovan said that he was a physician on the active staff of that hospital and his own patients slept in a ward aligned against the Mile End-road. If Sir G. Hamilton would offer new trams he would withdraw what he had said, but he knew these ancient vehicles.

Sir G. Hamilton said that they were not dealing with the ancient trams, but with new overhead equipment. That equipment would not cause any noise which would disturb the patients of the London Hospital.

Dr. O'Donovan said that he would withdraw his amendment because there were other and constitutional means open to a borough council but not open to a Member of Parliament which could be employed to test the feeling of Parliament on this matter.

The amendment was by leave withdrawn and the Bill was read the third time.

The Milk Bill and Pasteurisation

On June 25th in the House of Commons the Milk Bill was considered on Report.

On Clause 9 (payments for securing pure milk-supply),

Sir S. Cripps moved an amendment giving the Minister of Agriculture and the Secretary for Scotland power to exercise the powers conferred on local authorities under the Diseases of Animals Acts, 1894 to 1927, or any orders or regulations made thereunder, in the case of default of any local authority. He said that there were counties where there was very little inspection of dairy herds, while in others it was more systematic. If this power was given it would be very valuable.

Mr. Elliot, Minister of Agriculture, said that the confusion that would be caused by saying that the Ministry of Agriculture should carry out a duty which normally belonged to a local authority would be the worst possible thing in the administration of this scheme.

After further debate the amendment was negatived by 209 votes to 49.

Sir A. WILSON moved the following amendment:

For the purposes of this Act the words "pure and free from the infection of any disease" means milk which has: (*a*) not been treated by heat in such a way as to destroy or modify its natural characteristics and to which no foreign matter such as water, skimmed milk, fat, or other substances have been added, and is (*b*) of a standard of bacteriological purity and of nutritional content which shall be fixed from time to time by the Minister of Agriculture and the Minister of Health after a public inquiry at the cost of the Milk Marketing Board.

He said that the amendment proposed first to exclude pasteurised milk or milk treated in other ways from the scope of the Bill and from the scope of milk to receive subsidy from Government funds. The Hopkins Report on which he pinned his faith was exceedingly lukewarm in its references to pasteurisation. It avoided saying that it was beneficial.

Sir FRANCIS FREMANTLE said he thought they were all agreed that they did not want pasteurisation to be used in order to give the people bad or unclean milk in any other way. They all agreed that they would infinitely rather that the children should have pasteurised milk than milk which contained the germs of tuberculosis and other diseases which they knew produced fatal diseases and resulted in the deaths of 2500 children every year. Pasteurisation was only the second best, but it was much better to have a second best than something which was worse. He did not think the amendment was required.

Mr. SKELTON (Under-Secretary of State for Scotland) said that if the amendment was accepted it would go far to prohibit the pasteurisation of milk. There was no intention that any development of pasteurisation should take the place of the cleaning up of the herds so far as this clause was concerned. It might well be that under this Bill it would be worth while to make some investigation into the proper method of pasteurisation. The main method in which the money would be spent, however, would be in the cleaning up of the herds. To make the granting of money for the purpose of cleaning up the herds dependent on the milk reaching a particular standard of bacteriological purity and nutritional content seemed to take them very far away from the vitally important purpose of this clause. He asked that the amendment should not be pressed.

Sir A. WILSON withdrew his amendment.

The Report stage of the Bill was concluded.

HOUSE OF COMMONS

National Health Insurance: Children Leaving School

WEDNESDAY, JUNE 20TH

Captain FULLER asked the Minister of Health if he would consider the desirability of amending the National Health Insurance Act so as to include all persons within its scope who, on leaving school, would enter into insurable employment at 14 under the new Unemployment Bill.—Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) replied: I would refer my hon. friend to the reply given to a similar question on April 19th last.

Mr. RHYS DAVIES: Is the hon. Member aware that a large number of associations which have considered this problem have recently decided to make representations to the Ministry on the urgency of bringing these children within the national health insurance scheme; and will he look into the matter once again?

Mr. SHAKESPEARE: We shall certainly consider all representations that are made.

Diphtheria Immunisation

Mr. GROVES asked the Minister of Health how many cases of diphtheria and deaths from that disease had occurred in Dewsbury in immunised children since immunisation was first started in that town; and how many months had elapsed since the last inoculation before diphtheria developed in these cases.—Sir HILTON YOUNG replied: According to information furnished by the local authority, the number of cases of diphtheria and deaths therefrom occurring in "immunised" children was in—

	1932.	1933.	1934. Jan. 1st to June 13th
Cases ..	13	26	23
Deaths ..	4	2	3

The following Table shows the length of time which elapsed between the date of last inoculation and the *development of the disease*:—

Months.	1932.	1933.	1934.	Months.	1932.	1933.	1934.
2	3	—	—	13	—	1	—
3	3	3	—	14	—	2	2
4	2	2	1	15	—	3	—
5	3	—	1	16	—	—	1
6	2	1	—	17	—	—	3
7	—	1	—	18	—	5	—
8	—	3	—	19	—	1	1
9	—	2	—	20	—	1	1
10	—	—	—	21	—	—	5
11	—	—	3				
12	—	1	5		13	26	23

THURSDAY, JUNE 21ST

Sale of Contraceptives to Poor Persons

Mr. POTTER asked the Minister of Health whether at any of the centres established under his regulations contraceptive appliances were supplied at reduced prices or at the public expense to poor patients.—Sir E. HILTON YOUNG replied: I have not made any regulations on this subject, but have indicated to local authorities the extent to which, as I am advised, they are empowered under the statute law to make arrangements for the giving of contraceptive advice at institutions provided by them. The question of making a charge for any appliances supplied *by the local authorities is a matter within their discretion* and I have no complete information on this subject.

Mr. MOLSON: Would it be impossible for the Minister without legislation to relax the conditions which at present apply?

Sir HILTON YOUNG: That would depend upon the proposed relaxations. If the hon. Member has any in mind perhaps he will give me an opportunity of learning his views on the subject.

Appointments

City of London Maternity Hospital: GILBERT, BARTON, M.B., B.S. Lond., Resident Medical Officer; BERGER, B., M.B., B.Ch. Edin., Assistant Resident Medical Officer.

DATNOW, MORRIS, M.D. Liverp., F.R.C.S. Edin., M.C.O.G, Honorary Assistant Gynæcologist to the Royal Southern Hospital, Liverpool.

DUNBAR, J., M.B. Ch.B. Glasg., Surgeon at the Glasgow Roya Infirmary, Lecturer in Clinical Surgery at the Glasgow University and Hon. Consulting Surgeon to the Victor Infirmary, Helensburgh.

HEARN, R. J., M.D. Camb., assistant deputy corner for Cent District of London.

KNOTT, F. A., M.D. Lond., M.R.C.P. Lond., D.P.H., Dire of Bacteriological Department and Lecturer in Bacteriol Guy's Hospital.

London Fever Hospital.—The following appointments announced: WILLCOX, Sir WILLIAM, M.D., F.R.C.P. Lo and LAKIN, C. E., M.D., F.R.C.P. Lond., F.R.C.S. E Senior Physicians; HUNT, T. C., D.M. Oxon, M.R. Lond., and SMITH, K. SHIRLEY, M.D., F.R.C.P. Lo *Assistant Physicians.*

MACDONALD, GEORGE, M.B. Edin., D.P.H. Lond., Med Officer of Health to the Borough of Battersea.

MCGIBBON, J. E. G., M.B. Lond., D.L.O. Eng., Honorar Laryngologist and Aurist to the Royal Southern Hospital Liverpool.

Manchester Royal Infirmary.—The following appointments ar announced: BRYCE, A. GRAHAM, M.D. Manch., F.R.C Eng., Honorary Assistant Surgeon; BOLTON, N. M.B. Manch., F.R.C.S. Eng.; HOLT, R. L., M.B. Manc F.R.C.S. Eng.; SIMMONS, H. T., M.B. Manch., F.R.C.S. E WATKINS, K. H., M.B. Manch. and Lond., M.S. Lo F.R.C.S. Eng., Chief Assistants to the Surgical Units.

UNDERWOOD, E. A., M.B. Ch.B. Glasg., D.P.H., Medical Offic of Health, Shoreditch.

WYATT, R. B. H., M.B. Birm., D.P.H., deputy coroner fo Central District of London.

MEDICAL NEWS

University of Oxford

On June 21st the degree of D.M. was conferred on I. E. Harding.

University of Cambridge

On June 19th the degree of B.Chir. was conferred on S. J. Hadfield.

Dr. O. A. Trowell, university demonstrator in physiology, has been elected a fellow of St. John's College.

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B., B.CHIR.

Part I.: Surgery, Midwifery, and Gynæcology.—A. G. V. Aldridge, T. G. Armstrong, K. C. Bailey, R. H. Bailey, G Bates, H. H. Bayley, D. A. S. Blair, C. H. T. Bond, J. G. Chappel, L. A. Collins, F. H. Culshaw, F. J. Curtis, R. H. Dale, T. M. Daniel, S. M. Davidson, H. E. Dimsdale, W. H. Ekin, F. I. Evans, J. D. Fergusson, H. A. Hamilton, W. H. C. M. Hamilton, J. W. Hannay, E. E. Harris, G. R. Hawkes, N. G. Hulbert, R. M. Jones, A. M. Lester, F. D. M. Livingstone, E. B. McDowall, K. W. Martin, R. S. Morris, J. H. Moseley, W. S. Nutt, N. C. Oswald, J. R. Owen, A. R. Pope, M. S.-M. Rayner, J. S. Ross, A. G. Salaman, S. K. Sen, D. A. Smith, L. W. Spratt, R. J. Still, F. B. Turner, R. W. D. Turner, P. A. Walford, J. H. Walters, W. H. C. Watson, N. Whittaker, and W. F. Young.

Part II.: Physic, Pathology, and Pharmacology.—R. H. Bailey, A. M. Barrett, C. H. D. Bartley, H. H. Bayley, R. L. Benison, A. T. Blair, T. B. L. Bryan, R. C. F. Catterall, C. M. Cavell, J. R. Chambers, A. C. E. Cole, J. Collinson, J. G. Connell, A. H. Dunkerley, J. F. Edwards, C. E. Elliott, W. A. Elliott, F. I. Evans, S. M. Evans, J. D. Fergusson, R. I. N. Greaves, G. D. Hadley, E. A. M. Halsted, L. A. Hawkins, J. D. Hay, G. T. Hindley, N. G. Hulbert, A. Innes, B. S. Jones, R. A. Ke[illegible]en, A. M. Lester, R. E. K. Levick, M. W. Lloyd Owen, C. [illegible] Martin, L. C. Martin, M. K. Martyn, H. B. May, W. G. Q. Mil[illegible] G. S. W. Organe, B. H. Page, C. G. Pantin, C. G. Parsons, J. P. S. Peck, G. T. Pitts, T. A. Ratcliffe, W. F. Richards, M. A. Rugg-Gunn, S. B. H. Saunders, T. L. H. Shore, M. S. Spink, R. J. Still, D. J. Thompson, A. S. Till, R. W. D. Turner, J. H. Walters, G. L. Ward, M. Williams, H. W. Williamson, W. H. Wilson, and R. M. Yeo.

University of London

At a meeting of the senate on June 20th Prof. L. N. G. Filon, F.R.S., was re-elected vice-chancellor for the year 1934–35. It was resolved that on foundation day, 1934, honorary degrees should be conferred, among others, on Prof. Karl Pearson, F.R.S., and Sir Cooper Perry, M.D.

Three chairs at the new British Postgraduate Medical School were filled by the appointment of Dr. F. R. Fraser as professor of medicine: Dr. James Young as professor of obstetrics and gynæcology: and Dr. E. H. Kettle as professor of pathology. The appointments are dated from October 1st or as soon thereafter as may be practicable.

Dr. Fraser, who is at present university professor of medicine St. Bartholomew's Hospital, was born in 1885 and educated Edinburgh Academy and Christ's College, Cambridge, where obtained first-class in the natural sciences tripos (Part I . graduated in medicine at Edinburgh in 1910, and was appointed assistant in medicine at the hospital of the Rockefeller Institute, New York, in 1912, and assistant physician to the Presbyterian Hospital in 1914. After serving in France and at the Hampstead Heart Hospital he became consulting physician to Rhine Army. In 1920 he was appointed assistant director the medical professorial unit at St. Bartholomew's Hospital, later in the same year he succeeded Sir Archibald Garrod as director. In 1925 he re-visited the medical schools in U.S.A. Canada at the invitation of the Rockefeller Foundation, in 1927 gave the Goulstonian lectures of the Royal College of Physicians of London, taking as his subject cardiac dyspnœa. 1928 he lectured in Australia at the invitation of the Melbourne Postgraduate Com[illegible] again visited the United [illegible] Vanderbilt University. was [illegible] Commission till 1933. [illegible] rature have related to [illegible], heart disease, and exophthalmic goitre.

Dr. Young is obstetric physician to the Edinburgh Royal Maternity Hospital and gynæcologist to the Edinburgh Royal Infirmary. Born in 1883, he was educated at Heriot's School and the University of Edinburgh, where he graduated M.B. medicine in 1905. He obtained the fellowship of the Royal College of Surgeons of Edinburgh in 1908, and he has been a fellow of the British College of Obstetricians and Gynæcologists from its foundation. Since 1920 he has been lecturer in clinical obstetrics and gynæcology in the University of Edinburgh. "Textbook of Gynæcology" is now in its third edition and he collaborated with Munro Kerr, Haig Ferguson, and James Hendry in the "Combined Textbook of Obstetrics and Gynæcology." Dr. Young has devoted his attention specially to maternal mortality, and in collaboration with Prof. Miles Phillips and Dr. W. H. F. Oxley he wrote the section on the maternity services of Holland, Denmark, and Sweden, in the final report of the Departmental Committee on Maternal Mortality and Morbidity. For many years he has carried out investigations into the toxæmias of pregnancy and he has written a book incorporating the results of research on histological changes in the uterus during menstruation and pregnancy. During the war years he served in the Royal Army Medical Corps, and for some time was lieut.-colonel in command of a field ambulance in the 52nd Division. He was awarded the D.S.O.

Dr. Kettle has been university professor of pathology at St. Bartholomew's Hospital for the past six years. Born in 1882 he entered St. Mary's Hospital from Skipton School in 1901, and graduated as M.B. Lond. in 1907. After four years as pathologist to the Cancer Hospital, London, he returned to St. Mary's as first assistant pathologist in 1912. His text-book on "The Pathology of Tumours" first appeared in 1916, from which year, until the end of the war, he was attached as a civil surgeon to the 3rd London General Hospital. In 1920 he became pathologist to St. Mary's Hospital, and in 1924 went to Cardiff as professor of pathology and bacteriology in the University of Wales. While at St. Mary's he began the studies of infection and immunity which have led to the experimental researches on silicosis and other industrial diseases on which he is now especially engaged. His earlier published work is chiefly concerned with cancer and splenomegaly. Prof. Kettle has been examiner in pathology in the Universities of London, Cambridge, and Wales, and is at present examiner at Bristol and Glasgow. He was elected F.R.C.P. Lond. in 1931.

Dr. S. P. Bedson was appointed university professor of bacteriology (Goldsmiths' Company) at London Hospital medical college in succession to Prof. William Bulloch, who retires on Oct. 1st.

Dr. Bedson, who was born in 1886, has been senior Freedom research fellow at the London Hospital for the past eight years. Educated at Abbotsholme School and the University of Durham, he graduated in science in 1907 and in medicine in 1912. After post-graduate training at the Pasteur Institute he worked at the Lister Institute in London as British Medical research fellow in the year before the war. From August, 1914, to March 1916, he held a commission in the Northumberland Fusileers, and was wounded at Gallipoli. On transference to the Royal Army Medical Corps he was put in charge of bacteriological laboratories, and early in 1919 became assistant advisor in pathology to the Fifth Army. After two years in the bacteriological department of the Durham University College of Medicine he was appointed assistant bacteriologist to the Lister Institute in 1921, and was later seconded for work on foot-and-mouth disease. His research work has been principally on the blood-platelets and purpura and on filtrable viruses.

Dr. A. B. Appleton, fellow of Downing College and university lecturer in anatomy at Cambridge, was appointed to the university chair of anatomy at St. Thomas's Hospital, in succession to Prof. W. E. Le Gros Clark, as from Sept. 1st.

Dr. Appleton entered Downing College in 1907, and in the following year was elected a foundation scholar. He gained an entrance scholarship at St. Bartholomew's Hospital in 1911, having taken first classes in both parts of the natural sciences tripos. On qualifying in 1914 he was appointed a demonstrator of anatomy in Cambridge, but in October of that year went to France on active service with a commission in the Royal Army Medical Corps. After serving in Malta, Macedonia, and again in France, he resigned his commission in 1919 and was appointed senior demonstrator of anatomy at Cambridge: he was appointed lecturer in 1926. He was awarded the Raymond Horton-Smith Prize for his M.D. thesis in 1922 and the Symington prize of the Anatomical Society in 1923. His research work has been chiefly on the muscular system and the development and growth of bone.

The title of emeritus professor of bacteriology was conferred on Dr. William Bulloch, F.R.S., on his retirement from the Goldsmiths' Company's chair of bacteriology at the London Hospital, and that of emeritus professor of ethnology on Dr. C. G. Seligman, F.R.S., on his retirement from the university chair of ethnology at the London School of Economics.

The date of the appointment of Prof. Karl Pearson as Heath Clark lecturer was changed from 1934 to 1935, and Dr. L. W. Hackett, assistant director of the international health division of the Rockefeller Foundation, was appointed for the year 1934.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—R. M. Outfin, Guy's Hosp. and Univ. of Bristol.

Medicine.—G. A. Bell, Guy's Hosp.; G. W. Bender, St. Mary's Hosp.; P. E. Cresswell, Univ. of Oxford and Guy's Hosp.; C. McK. Johnston, King's Coll. Hosp.; S. Klein, Univ. of Vienna and St. Mary's Hosp.; and A. Lassman, Univ. of Manch.

Forensic Medicine.—G. W. Bender, St. Mary's Hosp.; P. E. Cresswell, Univ. of Oxford and Guy's Hosp.; C. McK. Johnston, King's Coll. Hosp.; and S. Kay, Univ. of Toronto.

Midwifery.—W. C. Campbell, Univ. of Birm.; W. McC. Graves Morris, Guy's Hosp.; H. W. John, St. Mary's Hosp.; S. Kay, Univ. of Toronto; and G. F. Metcalf, Univ. of Leeds.

Having completed the final examination, S. Kay and G. F. Metcalf have been granted the diploma of the society entitling them to practise medicine, surgery, and midwifery.

University of Leeds

Mr. E. R. Flint has been elected to the chair of clinical surgery in the university.

Mr. Flint qualified in 1905 and graduated at Leeds University in the following year, proceeding to the Fellowship of the Royal College of Surgeons of England in 1912. He held resident appointments at the Leeds General Infirmary and elsewhere, and before joining the honorary staff was surgical tutor at the Infirmary. He delivered Arris and Gale lectures before the Royal College of Surgeons of England in 1923 and 1930—his subjects being abnormalities of the hepatic and cystic arteries and bile-ducts and the association between gall-bladder lesions and hepatitis—and a Hunterian lecture on preoperative procedure appeared in our columns last year. Mr. Flint is surgeon to the General Infirmary at Leeds and for some years has acted as honorary demonstrator of physiology at the Leeds School of Medicine. On his new appointment he will retain his position as director of surgical research.

University of Glasgow

On June 20th the honorary degree of LL.D. was conferred on Prof. René Leriche of the faculty of medicine of Lyons. The following ordinary degrees were also conferred :—

D.Sc.—William James Hamilton, M.B., and Thomas Nicol, M.B.

M.D. (with honours).—D. Baird and J. M. Johnston ; (*with* [illegible] ain, W. Blyth, [illegible]

The history of medicine prize has been awarded to Dr. W. J. Rutherford.

Dr. Archibald Harrington has been appointed to the Muirhead chair of medicine in succession to Prof. W. K. Hunter, who is to retire on September 30th.

Dr. Harrington graduated in medicine at the University of Glasgow in 1900 and became M.D. in 1903. After holding numerous junior appointments at general and special hospitals in Glasgow, he was appointed assistant physician, and later physician, to the Glasgow Fever Hospital, Ruchill. He also served on the honorary staff of the Bellahouston Hospital. Elected F.R.F.P.S. in 1912, he is at present visiting physician to the Royal Infirmary and lecturer and examiner in clinical medicine in the university. His published work deals with a large variety of medical problems.

Epsom College

Lord Leverhulme, the new president, took the chair at the 81st annual general meeting of the governors of the college, which was held at the office, 49, Bedford-square, W.C.1, on June 22nd. In presenting the council's annual report he emphasised the importance of the appeal for new governors in order to enlarge the activities of the foundation. He pointed out that possibly no profession felt the effects of a period of depression more acutely than the medical profession, whose voluntary work in such times was as much increased as their private practice was diminished. It was all the more necessary, therefore, to help as many as possible of the large and ever-growing number of applicants for pensionerships and foundation scholarships. This year the list of successful foundationers contains the names of boys whose fathers practised in Glasgow, Stepney, Shropshire, Peterborough, London, Sierra Leone, and the military and naval medical services. A list of the successful candidates appeared in our last issue.

Medical Reunion in Vienna

The dates of this reunion, which was announced in our issue of June 9th (p. 1264), have been changed, and it will now be held from July 29th to August 4th.

Fellowship of Medicine and Post-Graduate Medical Association

Dr. Clark-Kennedy will give a lecture-demonstration on High Blood Pressure at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, on Tuesday, July 10th, at 2.30 p.m. A week-end course in general medicine and surgery will be given at the General Hospital, Southend-on-Sea, on Saturday and Sunday, July 7th and 8th. There will be a course in dermatology at the Blackfriars Skin Hospital from July 9th to 21st, and a course in urology at the All Saints' Hospital from July 9th to 28th. Dr. Peter Kerley will give three X ray demonstrations for M.R.C.P. candidates at the rooms of the Medical Society of London at 8.30 p.m. on Monday, July 2nd, Wednesday, July 4th and Friday, July 6th. On Saturday, July 14th, Dr. W. J. O'Donovan will give a demonstration of dermatological cases at 3 p.m. at the National Temperance Hospital. Further particulars may be had from the secretary of the Fellowship, Wimpole-street, London, W.1.

Royal Medico-Psychological Association

The ninety-third annual meeting of this association will be held from July 4th to 6th at the Guildhall, Northampton, under the presidency of Dr. D. F. Rambaut, superintendent of St. Andrew's Hospital, Northampton, who will deliver a presidential address entitled Some Mental Treatments. Other speakers will include Mrs. Eleanor C. Slagle, director of occupational therapy in the New York State department of mental hygiene (occupational therapy) ; Dr. Henry Yellowlees (modern psychiatry and mental hospitals); Dr. Rolf Ström-Olsen (results of treatment by prolonged narcosis) ; and Dr. D. C. L. Paddle (lumbar puncture and the cerebro-spinal fluid in 2000 mental defective cases). The secretary of the association is Dr. R. Worth, Springfield Mental Hospital, near Tooting, London, S.W.17.

Training of Nurses: Committee of Inquiry in Scotland

The Secretary of State for Scotland has appointed a committee "to enquire into the training and system of registration of nurses in Scotland and to recommend what amendments, if any, should be made in the Nurses Registration (Scotland) Act, 1919, or the rules made thereunder, and what other steps, if any, should be taken to improve the existing system of training and registration." The members of the committee are : Sheriff A. Campbell Black, K.C. (chairman) ; Dr. W. L. Burgess, medical officer of health, Dundee ; The Lady Susan Gilmour Queen's Institute of District Nursing ; Dr. Mary R. Knight, medical superintendent, Paisley District Asylum ; Mr. T. B. M. Lamb, Scottish Education Department ; Sir Henry Mechan, Western Infirmary, Glasgow ; Dr. John Reid, medical superintendent, County Hospital, Motherwell ; Miss Elizabeth D. Smaill, matron, Edinburgh Royal Infirmary ; Miss Christina Whyte, matron, Robroyston Hospital, Glasgow ; and Dr. John Young, Falkirk and District Royal Infirmary. The secretary of the committee is Mr. W. T. Mercer, of the Department of Health for Scotland, 121a, Princes-street, Edinburgh, to whom all communications should be addressed.

Silicosis and Asbestosis

The Home Secretary has given notice that he proposes to amend paragraph 12 of the Silicosis and Asbestosis (Medical Arrangements) Scheme, 1931, which provides for the initial medical examination of workmen newly engaged for employment in certain occupations. Copies of the draft amending scheme may be had on application to the Industrial Division, Home Office, Whitehall, London, S.W.1.

Oxford Ophthalmological Congress

This congress meets at Keble College, Oxford, on the evening of next Wednesday, July 4th, and on the following morning after a welcome by the Master, Mr. Cyril Walker, there will be a symposium on functional diseases of the eye, the speakers including Sir Farquhar Buzzard, Mr. F. Williamson-Noble, and Dr. William Brown. Mr. R. Affleck Greeves will report a case of retinal glioma treated by radium externally. In the afternoon Dr. H. W. Barber is to give an address on the ætiology and treatment of some conditions affecting the eyelids, and there will be a number of demonstrations ; in the evening the annual dinner will be held in Keble College. On the morning of Friday Dr. Thomson Henderson will speak on the constitutional factor in myopia, and Mr. Arnold Sorsby on the pre-myopic state, and Prof. Joseph Meller, of Vienna, will deliver the Doyne memorial lecture on tuberculosis and its relation to spontaneous post-traumatic and sympathetic ophthalmia. Communications in the afternoon include papers on the influence of diet in ophthalmic practice (Dr. Oliver Pratt), thermoplasty of the extra-ocular muscles (Mr. Bernard Chavasse), and the ætiology and treatment of congestive glaucoma (Mr. J. Jameson Evans and Mr. P. Jameson Evans [illegible] Saturday morning Mr. F. Ridley will speak on the clinical significance of the composition of the tears, and Mr. L. H. Savin on uveoparotid fever. The address of the hon. secretary, Mr. C. G. Russ Wood, is Hill House, Abberbury-road, Iffley, Oxford.

Medical Diary

formation to be included in this column should reach us roper form on Tuesday, and cannot appear if it reaches ater than the first post on Wednesday morning.

SOCIETIES

YAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, July 3rd.
Annual General Meeting of the Society. 5 P.M.
FRIDAY.
Obstetrics and [illegible] Discussion in conjunction [illegible] y on Sex: Its Nature [illegible] from Biological and Legal Points of View. To be opened by Prof. F. A. E. Crew, Dr. H. Gardiner-Hill, Sir Bernard Spilsbury, and Lord Riddell. Members of the Section of Medicine are specially invited.

ICO-LEGAL SOCIETY.
See under ROYAL SOCIETY OF MEDICINE.

TH-WEST LONDON POST-GRADUATE ASSOCIATION.
WEDNESDAY, July 4th.—Visit to the Heritage Schools, Chailey, Sussex. Mrs. C. W. Kimmins.

FORD OPHTHALMOLOGICAL CONGRESS.
THURSDAY, July 5th, to SATURDAY.—Annual Meeting at Oxford.

YAL MEDICO-PSYCHOLOGICAL ASSOCIATION.
WEDNESDAY, July 4th, to FRIDAY.—Annual Meeting at Northampton.

ECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LLOWSHIP OF MEDICINE AND POST-GRADUATE EDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, July 2nd, to SUNDAY, July 8th.—PRINCE OF WALES'S HOSPITAL, Tottenham, N. All-day Course in Medicine, Surgery, and the Specialties.—NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W. All-day Course in Cardiology (open to non-members).—CHILDREN'S CLINIC, Cosway-street, Marylebone-road, N.W. Course in Children's Diseases.—GENERAL HOSPITAL, SOUTHEND-ON-SEA. Week-end Course in Medicine and Surgery. All day, Sat. and Sund.—MEDICAL SOCIETY OF LONDON, Chandos-street, W. Demonstrations of X Rays by Dr. Peter Kerley, at 8.30 P.M. on Mond., Wed., and Frid. (Specially suitable for M.R.C.P. candidates.)—PANEL OF TEACHERS. Individual clinics in various branches of medicine and surgery are available daily.—Courses of instruction, clinics, &c., arranged by the Fellowship of Medicine are open only to Members and Associates unless otherwise stated.

IVERSITY OF BIRMINGHAM.
TUESDAY, July 3rd.—3.30 to 5 P.M. (at the Children's Hospital), Dr. J. M. Smellie: Pulmonary Fibrosis and Allied States.
FRIDAY.—3.30 to 5 P.M. (at the Queen's Hospital), Mr. R. K. Debenham: Minor Operative Procedures.

Vacancies

For further information refer to he advertisement columns

berdeen, P.H. Dept.—Asst. M.O.H. £600.
berdeen University.—Lecturer in Morbid Anatomy. £400.
ccrington Victoria Hospital.—H.S. £150.
yr County Hospital.—Res. H.S. At rate of £125.
angor, Caernarvonshire and Anglesey Infirmary.—Jun. H.S. At rate of £100.
th, Royal United Hospital.—H.S. and Out-patient and Cas. O. Each at rate of £150.
irkenham C.B.—Res. Asst. M.O. £350.
irmingham and Midland Eye Hospital.—Third H.S. At rate of £100.
ambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
ambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency Officer. At rate of £130.
hester, Barrowmore Hall, Great Barrow.—H.P. At rate of £100.
esterfield and North Derbyshire Royal Hospital.—H.S. At rate of £150.
lchester, Essex County Hospital.—H.P. £150.
nnaught Hospital, Walthamstow, E.—H.S. At rate of £100.
genham Urban District Council.—M.O.H. £900.
rizes, Wilts County Mental Hospital.—Med. Supt. £900.
rham County Hospital.—Two H.S.'s. Each £150.
Ham Memorial Hospital, Shrewsbury-road, E.—Hon. Ophth. Surgeon.
Ham and Southend-on-Sea Mental Hospital.—Med. Supt. £900.
inburgh Corporation, Venereal Diseases Scheme.—Clin. M.O. £750.
olkestone Royal Victoria Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £150 and £120 respectively.
oucester, Gloucestershire Royal Infirmary, &c.—H.P. and H.S. Each at rate of £150.
imsby and District Hospital.—Sen. and Jun. H.S.'s. £200 and £150 respectively.
ildford, Royal Surrey County Hospital.—H.S. £150.
ampshire County Council.—Asst. County M.O. £600.
ospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. At rate of £50.
ospital Français, 172, Shaftesbury-avenue, W.C.—Physician to In-patients. Also Otolaryngologist for Out-patient Dept.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W. Res. H.P. At rate of £100.
Hospital for Sick Children, Great Ormond-street, W.C.—Three Out-patient Surgical Registrarships. Each £200.
Huddersfield Royal Infirmary.—2 H.S.'s. Each at rate of £150.
Hull Royal Infirmary.—Cas. O. At rate of £150.
Hull Royal Infirmary.—Third H.S. At rate of £150.
Indian Medical Service.—Commissions.
King Edward Memorial Hospital, Ealing.—Jun. Res. M.O. At rate of £150.
Leamington Spa, Warneford General Hospital.—Res. H.S. to Cas. and Special Depts. At rate of £150.
Leicester, Leicestershire and Rutland Mental Hospital, Narborough. Sen. Asst. M.O. £550.
Lincoln County Hospital.—Jun. H.S. At rate of £150.
Llanelly and District Hospital.—H.S. £150.
London Hospital, E.—Hon. Asst. Anæsthetist.
London Homœopathic Hospital, Great Ormond-street, W.C.—Res. M.O. £100.
London Lock Hospital, 91, Dean-street, W.—Surg. Reg. £100.
Manchester, Ancoats Hospital.—H.S. to Special Depts. At rate of £100.
Manchester, Booth Hall Hospital for Children.—Dept. Med. Supt. £550. Res. Surg. O. Also Jun. Asst. M.O.
Manchester, Christie Hospital and Holt Radium Institute.—Radiological Asst. M.O. £450.
Manchester, Crumpsall Hospital &c.—Deputy Med. Supt. £600. Res. Surg. O. £400. Res. Obstet. O. At rate of £300. Also Two Jun. Asst. M.O.'s. Each at rate of £200.
Manchester Royal Children's Hospital.—Res. M.O. At rate of £125.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Manchester, St. Mary's Hospital.—Three H.S.'s to Special Depts. Each at rate of £50.
Manchester, Withington Hospital, &c.—Deputy Med. Supt. £600. Res. Surg. O. £400. Also Three Jun. Asst. M.O.'s. Each at rate of £200.
Mansfield, Harlow Wood Orthopædic Hospital.—Two H.S.'s. Each at rate of £175.
Margaret-street Hospital for Consumption and Diseases of the Chest, W.—Hon. Asst. Phys. and Hon. Asst. Radiologist.
Middlesex C.C.—Dist. M.O.'s and Public Vaccinators. £50 and £100.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Asst. Cas. O. Also Jun. Res. M.O. At rate of £125 and £100 respectively.
Miller General Hospital, Greenwich-road, S.E.—Cas. O. At rate of £150.
National Temperance Hospital, Hampstead, N.W.—Hon. Asst. Surgeon.
Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. and H.S. At rate of £100.
Newcastle-upon-Tyne Hospital for Sick Children.—Res. Surg. O. £250.
New Zealand, Wellington Hospital Board.—Res. Surg. O. £400.
Northampton General Hospital.—H.S. to Ear, Nose and Throat Dept. At rate of £150.
Plymouth, S. Devon and E. Cornwall Hospital.—Res. Anæsthetist and H.S. to Spec. Depts. At rate of £120.
Prince of Wales's General Hospital, W.—Hon. Physician to Children's Dept.
Princess Elizabeth of York Hospital for Children, Shadwell, E.—Dermatologist.
[illegible] næsthetist. £150.
[illegible] *Portland-street, W.*—
[illegible] te of £150.
[illegible] to X Ray Diagnostic Dept.
St. John's Hospital, Lewisham, S.E.—H.P. and Cas. O. Each at rate of £100.
Salisbury General Infirmary.—H.S. and H.P. Cas. O. Each at rate of £125.
Scarborough Hospital and Dispensary.—H.S. At rate of £175.
Sheffield Children's Hospital.—H.S. Also H.P. Each at rate of £100.
Sheffield Royal Infirmary.—M.O. to Assist Medical Director at Sheffield Radium Centre.
Sheffield Royal Infirmary.—Ophth. H.S. At rate of £80–£100.
Shoreham-by-Sea, Southlands Hospital.—Asst. M.O. Temporary Asst. M.O. £350.
Southampton, Royal South Hants and Southampton Hospital.—Cas. O. At rate of £150.
Southend-on-Sea General Hospital.—H.S. At rate of £100.
Southern Rhodesia Medical Service.—Government M.O. £600.
Stockport Infirmary.—H.S. £150.
Taunton and Somerset Hospital.—H.P. At rate of £100.
Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. Surgeon.
Willesden General Hospital, Harlesden-road, N.W.—Hon. Phys. to Skin Dept.
Witham, Essex, Royal Eastern Counties Institution.—Med. Supt. £600.
Wolverhampton Royal Hospital.—H.P. At rate of £125. Also Asst. Res. M.O. and H.S. to Spec. Depts. Each at rate of £100.
Worcester Royal Infirmary.—H.P. £160.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Liverpool, Garston, Lancs.; and at Mullion, Cornwall.

NEW WING OF KING GEORGE HOSPITAL, ILFORD. On Saturday last the foundation-stone of a new wing was laid by Mr. Henry T. Becker, who has given £25,000 towards the cost. The wing will accommodate 58 patients.

NOTES, COMMENTS, AND ABSTRACTS

JOINT LUBRICATION

BY ERIC SHIRLEY JONES, M.R.C.S. Eng.

AN animal joint and a machine bearing have this in common: each consists of two accurately opposed solid surfaces separated by a film of fluid lubricant. The importance which the engineer attributes to this film is well known. He recognises two separate states of lubrication[1]:

(*a*) *Fluid film or "perfect" lubrication*, in which a film of liquid lubricant one or two thousandths of an inch thick separates the solid surfaces. In this state friction is independent of load, and is only dependent on the viscosity, or resistance to shear, of the oil film. This is the state of lubrication aimed at by all machine designers, and is the state which almost certainly obtains in a healthy joint working under favourable circumstances.

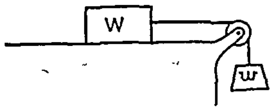

FIG. 1.—Measurement of coefficient of friction for two plane surfaces.

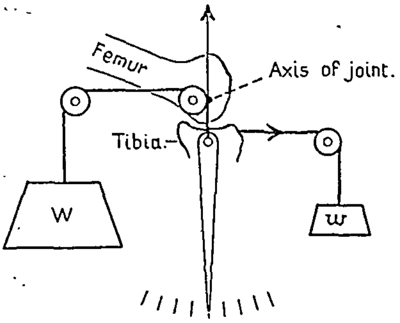

FIG. 2.—Measurement of coefficient of friction of a joint.

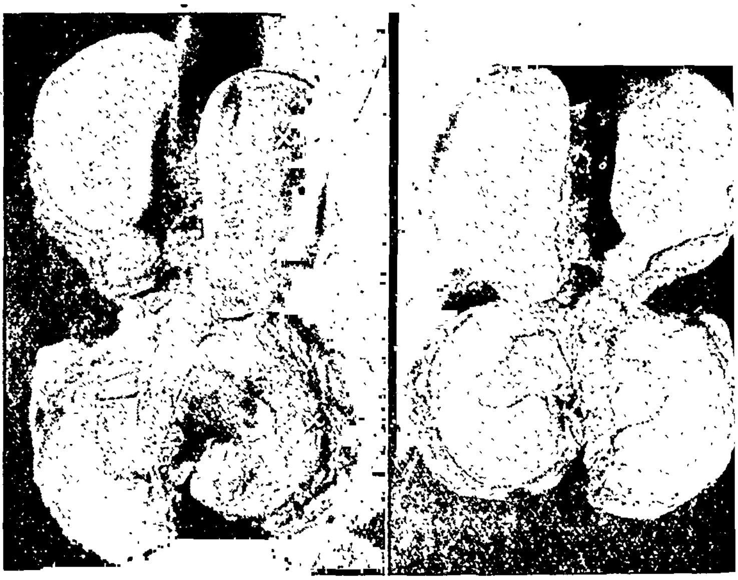

FIG. 3.—Test joint (left of Figure) and control joint (right). The test joint sho signs of wear over the areas marked x.

(*b*) *Boundary layer lubrication.*—The molecules of oil in contact with a metal surface become "adsorbed" to the metal and act, no longer as a liquid, but as a greasy solid. The state of affairs when two such layers are in contact is called "boundary layer" lubrication. In this state friction is proportional to load, and follows the ordinary laws governing solid friction. The viscosity (resistance to change of shape) of the oil no longer counts, but another property called "oiliness" becomes the dominant factor in friction reduction.

The engineer recognises this state as an unavoidable evil, which will occur under conditions of heavy load, low speed, or at stopping and starting. It is probable that this state also occurs in joints. The cracking of joints on being moved after rest is difficult to explain unless we assume an absence of the fluid film.

The essential characteristics for a fluid lubricant appear to be three:

1. It must wet the surfaces to be lubricated.
2. It must possess viscosity to prevent its being squeezed out under load.
3. It must possess "oiliness" to prevent friction when boundary layer conditions occur.

Synovial fluid obviously satisfies the first condition. In the following results (Table I.) viscosity has been measured by the Hess viscometer. This instrument consists of two parallel capillaries, along which w and the fluid to be measured are simultaneo aspirated. The result is expressed in times viscosity of water. Forkner[2] has found viscos of synovial fluid to range from 2·91 to 4·79 in hea and from 2·7 to 16·7 in chronic arthritis. Pembert agrees with these figures, and some of the appen results are in fair agreement. Kling[4] has shown the viscosity of synovial fluid is due to its mu and that, when this is removed, the viscosity d to that of a simple exudate.

My attempts to measure "oiliness" of synovial under "boundary layer" conditions have so far fai although surfaces of glass, ebonite, wood, cast i rubber, and articular cartilage have all been tried.

THE COEFFICIENT OF STATIC FRICTION FOR TW PLANE SURFACES

When the small weight (w) is just large enoug cause the large weight (W) to move, the coeffic of static friction $\mu = w/W$. (Fig. 1.) This fractio independent of the load W, and depends only on character of the surfaces.

Since a joint has curved surfaces it is essential t the resultant of the load (W) shall pass through axis of the joint. Otherwise the load will ca movement and vitiate the result. To satisfy th conditions, a horse's stifle joint was set up in a fra so that the femur was fixed and the tibia free move. (Fig. 2.) Through the tibia was passed a st pin, and cords from this were passed over pulleys the loads (W). These pulleys were on an adjusta carriage, and this was adjusted until the tibia wo remain in any position through a small arc, show that the resultant of the weights (W) passed through axis of the joint. Capsule and ligaments were sever and the measurement was taken working downward, prevent a sticking tendency that otherwise develop

	w/W	= μ (coefficient of frictio
With synovial fluid ..	$\frac{10}{448}$ ounces	= 0·02.
With normal saline ..	$\frac{9}{448}$,,	= 0·02.
Surfaces allowed to dry	$\frac{122}{448}$,,	= 0·27.
